THE
GARDENERS' DICTIONARY:

CONTAINING

The BEST and NEWEST METHODS

OF

CULTIVATING and IMPROVING

THE

Kitchen, Fruit, Flower Garden, and Nursery;

As also for Performing the

Practical Parts of AGRICULTURE:

INCLUDING

The MANAGEMENT of VINEYARDS,

WITH THE

Methods of MAKING and PRESERVING WINE,

According to the present Practice of

The most skilful Vignerons in the several Wine Countries in *Europe*.

TOGETHER WITH

DIRECTIONS for PROPAGATING and IMPROVING,

From REAL PRACTICE and EXPERIENCE,

ALL SORTS OF TIMBER TREES.

THE EIGHTH EDITION,

Revised and Altered according to the latest SYSTEM of BOTANY; and
Embellished with several COPPER-PLATES, which were not in some former Editions.

By PHILIP MILLER, F. R. S.

Gardener to the Worshipful Company of APOTHECARIES, at their Botanic Garden
in *Chelsea*, and Member of the Botanic Academy at *Florence*.

. . . . *Digna manet divini gloria ruris.* VIRG. Georg.

L O N D O N,

Printed for the AUTHOR;

And Sold by JOHN and FRANCIS RIVINGTON, at No. 62, *St. Paul's Church-yard*; A MILLAR,
J. WHISTON, W. STRAHAN, J. HINTON, R. BALDWIN, B. WHITE, L. HAWES and
W. CLARKE and R. COLLINS, W. JOHNSTON, T. CASLON, S. CROWDER, T. LONGMAN,
B. LAW, C. RIVINGTON, J. DODSLEY, W. GRIFFIN, T. CADELL, T. LOWNDES,

M. DCC. LXVIII.

To the Most Noble

H U G H,

Duke and Earl of NORTHUMBERLAND,

E A R L P E R C Y,

Baron WARKWORTH of Warkworth Castle,

**Lord Lieutenant and Custos Rotulorum of the Counties of
MIDDLESEX and NORTHUMBERLAND,**

Of the City and Liberty of WESTMINSTER,

And of the Town and County of NEWCASTLE upon TYNE,

VICE ADMIRAL of all AMERICA,

And of the County of NORTHUMBERLAND,

One of his MAJESTY's Most Honourable Privy Council,

Knight of the Most Noble Order of the GARTER,

And Fellow of the ROYAL SOCIETY.

MAY IT PLEASE YOUR GRACE,

OUR Grace's kind Acceptance of two former Editions of this Work, has emboldened me to lay this at Your Grace's Feet, as a public Acknowledgment of the many useful Observations and Instructions, which Your Grace has at several Times communicated to me for its Improvement. If I have been so happy as to employ them in such manner, as to merit Your Grace's Approbation, I shall have less Reason to doubt that of the Public; since the most skilful Persons in this useful Branch of Science, pay the highest Regard to Your Grace's Judgment.

The many Improvements which Your Grace is annually making so happily upon Your various Estates, sufficiently demonstrate Your Grace's superior Judgment; but more particularly in a Country almost destitute of Timber: Where, if Your Grace continues planting, so ardently as for several Years past, the whole Face of the Country will be much altered for the better, and Your Grace's Estate thereby greatly improved.

That Your Grace may long live to continue these Improvements, and to be an Example to others, is the sincere Wish of

Your GRACE'S

Most obedient humble Servant,

CHELSEA,
March 1, 1768.

Philip Miller.

P R E F A C E.

THE GARDENERS DICTIONARY having already gone through several editions, it may reasonably be supposed, the public are well acquainted with the nature of it, which renders it less necessary to enlarge on that subject. The author therefore thinks himself obliged to return his thanks for the kind reception his work has met with.

But as there may be some, who may think that the republishing it is doing them an injury, especially those who have purchased a former edition, it may not be amiss to make some apology for this.

When the first edition was published, gardening was then much less known than at present; and therefore, as the knowledge of the art increased, it became more necessary to enlarge on the subject, by adding the new improvements to the former, without which it would have been deemed imperfect; for as the author's situation in life rendered him capable of being well informed of the progress made in the art, by his great correspondence both at home and abroad, he thought it would not be displeasing to communicate those improvements to the public: in doing which, he has been careful not to publish any thing imparted to him, until he was fully satisfied of the facts by experiments.

Others have suggested, that printing the improvements separately would give ample satisfaction in this point; but the author had made trial of former purchasers some years past, by publishing several sheets of new articles, by way of Supplement, for which there was scarce any demand; so that the few which were sold, would not defray the expence of paper and printing.

As the number of plants now cultivated in England, are more than double those which were here when the first edition of this book was published, the mentioning of them, together with their culture, could not well be avoided in a work of this nature, therefore the author hopes his care in inserting them will not be censured.

From the title of this book it may seem to be only a Dictionary on the art of gardening, but all the branches of agriculture are included in it, in a more complete manner than can be found in any other book extant, though written wholly on the same subject. Nor are the instructions here given for performing the work in every part taken up hastily, or upon slight experiment; but most of them are the result of more than twenty years practice in different parts of England, where the author has been permitted to superintend and direct the whole: therefore he can assure the public he has been very cautious in recommending any thing, which he is not thoroughly convinced to be true.

It is amazing to see, in most of the books which have been published concerning husbandry, that scarce any of the compilers have taken the least notice of the common practice of sowing eight times the quantity of Corn upon land that is necessary, to the great expence and detriment of the farmers, who are so wedded to their old customs, as not to be convinced of the error: for so obstinate are they in this matter, that unless the whole ground be covered with the blades of Corn by the spring, they judge it not worth standing, and in consequence thereof frequently plough up their Wheat and winter Corn, to sow the land with Barley, or other Lent Corn; whereas, if the former had been left standing, it would have produced a better crop than any land can do where the blades are very thick, as the author has frequently observed. I have mentioned this to several farmers, but the answer has constantly been, that on rich ground a thin crop of roots will often produce a large crop of Corn, but on poor land it will not pay cost, which is a very great absurdity; for how is it possible, that bad land can supply proper nourishment to a greater number of roots than better ground? and where this practice is observed, seldom more than three or four bushels are reaped from one sown; whereas, where the same quantity is sown upon the same, or a like soil, and has room to grow, the produce will be at least six or seven bushels. Yet I have seen growing upon land not very good, and uncultivated, for more than twenty years, which and was sown with

Wheat in drills, where three gallons of seed were allowed to an acre, a produce of nine quarters per acre; now this is no more than an eighth part of the seed usually sown by farmers, who seldom reap more than one-third of this produce; by which it appears plainly, that in the common method of husbandry, there is at least eight times the quantity of seed sown upon the land that is necessary. How great a saving this would be in a whole country, I leave every one to judge, especially in scarce years, when Corn is dear; and what an expence is occasioned by the contrary practice to the farmers, who notwithstanding seem unwilling to alter their ancient customs. These matters are treated of under the articles AVENA, HORDEUM, SECALE, and TRITICUM.

Nor are the common farmers better managers of their pasture lands; for on them they seldom are at the trouble of rooting up bad weeds, which frequently over-run them; these are often permitted to scatter their seeds, by which the land is stocked with a supply of weeds for seven years or more, tho' the utmost care be taken afterward to destroy them: but tho' there are some farmers who may be supposed more careful in this respect, yet these leave in their head lands, and on their banks, hedge-rows, and the sides of ditches, a sufficient number of weeds to stock their fields when the seeds are permitted to scatter: beside, these pastures have rarely a sufficient quantity of manure allowed them, especially where there is much arable land; nor is the dressing laid on at a proper season; the general rule with most of the farmers being to carry and spread the dung upon their pastures, soon after the crop of hay is taken off the ground; and as this is done in summer, the heat of the sun draws all the moisture from it, whereby the greater part of its goodness is evaporated and lost. But as these points are more fully treated of in the body of this work, the author desires the reader to refer to them.

On the article of TIMBER perhaps many may suppose, the author has been too diffuse in his instructions; but if those who are of that opinion will only consider, how material an article this is to the welfare of this country, he flatters himself they will change their sentiments, especially when they reflect upon the great waste that has been made of it for many years past; as also that the persons now employed by the government to cultivate and improve it, deriving their own profits from the waste of timber, seem to think, that as their predecessors have long practised it, they have a right to do the same; this is now carried to so great an extravagance, that unless a speedy stop be put to it, the government will be greatly distressed for their marine. For although this practice began in the Royal Forests, &c. yet several of the nobility and gentry, who had very great quantities of timber growing upon their estates, have destroyed a considerable part of theirs also; therefore, from a due regard for the public, the author has treated of the best methods for propagating and preserving timber, which he hopes may not be displeasing to the generality of his readers.

The several plants here proposed for trial in the British dominions in America, are such as there is reason to believe will succeed in those parts where the experiments are desired to be made, and confined to such only, as may be of utility to the public, and real advantage to the inhabitants of those countries: furthermore, these experiments are proposed to be tried upon plants which will not succeed well in England, so as to render their culture practicable, and therefore will not interfere with the growth or trade of this country, and the consumption of which is very great here, many of them being of very considerable use in our manufactures, which cannot be carried on without them; as namely the Safflower, Indigo, and several other sorts used in dyeing, none of which will thrive in this country to advantage, with many medicinal drugs, which, if introduced into the islands of America, will certainly thrive there as well as in their native soils. Coffee and Chocolate grow equally well there; but the former being gathered before it is ripe, ill dried, and brought over to England in ships freighted with rum and sugars, the effluvia of these commodities are imbibed by the Coffee, whereby it is rendered less valuable: as to the latter, it was formerly cultivated by the Spaniards in the island of Jamaica, when they were in possession of it, so as to furnish the inhabitants with a quantity sufficient for their own consumption; whereas the English inhabitants now resident there, purchase it of the Spaniards: these articles therefore require the public attention, for if the above commodities may be easily produced in the British colonies in America, they will not only supply us with such as are genuine, but also turn the balance of trade, greatly to the advantage both of Great-Britain and her colonies.

It is also a great neglect of the inhabitants of the sugar islands in America, to commit the care of their plantations to overseers, who at best go on in their usual course, planting eight or ten sugar canes in each hill, so that if five or six of them grow, they will be so close as to spoil each other; for whenever these plants are stunted in their growth, they are soon attacked by vermin, which spread and multiply so greatly, as frequently to destroy the whole crop, or at least very much to damage it; and this they lay upon inclement seasons, calling it a blight, whereas it proceeds from their own covetous custom. A gentleman of learning, who had a considerable estate in Jamaica, which was bequeathed to him upon his arrival there, was determined to make trial of the horse-hoeing husbandry among

P R E F A C E.

among his canes. Accordingly he set out one acre of land in the middle of a large piece, which he caused to be planted with canes at five feet distance, putting but one to each hill; these grew to a very large size, and when ripe were cut, as also an acre from the best part of the piece in which the others were planted: each of them then were boiled separately to examine their produce, which was nearly equal in the weight of sugar; but where the plants grew single, the juice was boiled with a ninth part of the fuel which the other required, and he sold the sugar for six shillings per hundred weight more than he could get for the former. This shews what advantages may be expected, if the possessors of lands were careful to make trials.

The alterations made in the catalogues of trees and plants which are added at the end of the book, have been done to prevent swelling the work to too great a size, therefore their specific differences are not inserted at full length; but as their generical titles are mentioned, and the figures to each species denote them according to their respective species referred to in the body of the book, the reader is desired to turn to the several genera, where under each article, their species with their respective titles are inserted at length, as also their culture and natural places of growth. The use of these catalogues, especially to such as are not acquainted with the art of gardening, but particularly to those who set up for designers of gardens, may be of great service; for if this part of planting were duly attended to, there would not be so many absurdities committed, as are now to be found in most of these designs, where we often see some of the smallest growing shrubs placed, where the largest trees should have been planted.

In the whole of this performance, the author has principally aimed at rendering the instructions given, as clear and intelligible as possible to the practitioners, as well as to those who are less acquainted with the art; in every particular he has observed all possible regard to truth, not having advanced any thing as such, but what he has been fully convinced of by his own experience: he hopes therefore for indulgence from the public, for any imperfections or omissions which may appear in the book, since in a work of so great extent, it cannot be expected to be absolutely perfect, though it is humbly hoped there will not be found in it many faults.

Some errors of the press have accidentally crept in, occasioned by the author's other necessary avocations, which frequently called him into the country during the time it was printing; but as most of these are corrected, and are not besides of themselves of great importance, he hopes the candid reader will pardon them.

The Gardeners Kalendar, inserted in most of the former editions, is in this omitted, many editions of that piece having been printed in octavo; it is presumed therefore that few persons who have any inclination for the innocent diversion of gardening, are without it; and as the adding any thing to this work would have swelled it greatly, which the author wishes he could have still further shortened; and moreover it having been observed to him, by many of his friends, that few persons would chuse to turn over so large a volume, to find in it the articles they may have in a portable one, the omission of the Kalendar was thought more advisable.

In the last edition of this work, the author adopted in a great measure the system of Linnæus, which was the prevailing method of ranging plants then in use among botanists; but as many of the plants which were treated of in the Gardeners Dictionary, were not to be found in any of Linnæus's works then published, Tournefort's system was also applied to take in such as were not fully known to Dr. Linnæus; but since that time the learned professor having made great additions to his works, and those additions being generally consulted for the names of plants, the author has now applied Linnæus's method entirely, except in such particulars, where the Doctor not having had an opportunity of seeing the plants growing, they are ranged by him in wrong classes; as for instance, the *Ilex* or *Agrifolium* is ranged in his fourth class, with those plants whose flowers have four stamina or male organs, and four stigmas or female parts of generation; whereas those plants have male flowers upon some, and female upon other plants. The *Laurus* Linnæus has placed in his ninth class, with those plants whose flowers have nine stamina or male organs of generation, and one female part; but these plants should also be ranged in his twenty-second class, for all the species of this genus have male and female flowers on different plants. These, with some other alterations from Linnæus's system, have been made in this edition, where the author has given his reasons for so doing, which he hopes will be approved by the public.

Many plants are likewise omitted in this edition, several of them natives of England, but rarely cultivated in our gardens; as also many varieties accidentally arising from seeds, as are most of those with double flowers, which, if enumerated, would have swelled the book to an immoderate size; however, most of these varieties are casually mentioned, to inform the reader of their respective difference, which the author hopes will be deemed sufficient. But as the variety of fruits, as well as of esculent

P R E F A C E.

lent plants, have been most of them, at least the fine sorts, greatly improved by culture, they are fully treated of under their proper genera.

On this article a long series of observations has been made by the author, who for near fifty years has applied himself closely to this subject; for as many former botanists have enumerated a great number of varieties as so many species, the study of botany was thereby rendered greatly perplexed; some of the modern writers on this subject, by going into the contrary extreme, have abridged the species almost as much. Indeed it must be allowed, that ascertaining the real specific difference of plants, would be of great service to the science of botany; but this cannot be done otherwise, than from many years experience in their culture, especially by observing the varieties which arise from the same seeds, as also the difference produced by different soils and situations, which is frequently so great as to perplex very good judges in this matter. There are likewise many other varieties which have arisen from seeds, saved from plants, and grown near others of a different species, by which means they have partaken of both; but these hybridine plants rarely producing any seeds afterward, the alteration goes no farther.

Mentioned in this

W O R K.

A ROOT, *Radix*, is that part of a plant, by which it naturally receives its nourishment.

There are several sorts of these, as

A fibrous Root, *Radix fibrosa*, is that which consists only of fibres. See plate 1. fig. 3.

A tuberous Root, *Radix tuberosa*, is that which consists of an uniform fleshy substance, and is of a roundish figure. See plate 1. fig. 1, 2. where it is cut horizontally through the middle.

A bulbous Root, *Radix bulbosa*, is that which consists of several coats involving one another, as is shewn plate 1. fig. 4, 5. or of several scales lying over one another, as in plate 1. fig. 6. The first of these is called a tunicated Root, the last a squamous Root.

A granulous Root, *Radix granulosa*, is a kind of grumous root, with small knobs resembling so many grains of Corn. See plate 1. fig. 7.

A testiculated Root, *Radix testiculata*, is a double tuberous root, consisting of two fleshy knobs resembling a pair of testicles. See plate 1. fig. 8.

An asphodel Root, *Radix asphodeli*, is a kind of grumous root, whose fleshy fibres swell into large knobs toward the bottom, resembling the dugs of animals. See plate 1. fig. 9.

A grumous root, *Radix grumosa*, is one which is composed of several fleshy knobs ending in fibres. See plate 1. fig. 10.

A Stalk, *Caulis*, is a part of a plant, receiving the nourishment from the root, and distributing it into the other parts with which it is clothed, not having one side distinguishable from the other. The stalk of a tree is called the trunk or stem, i. e. *Caudex*.

A Branch, *Ramus*, is the division of a stalk. In trees it is generally called a bough.

A Pedicle, *Pediculus*, is that part of a stalk, which immediately sustains a leaf, a flower, or a fruit. Dr. Linnæus has distinguished these. Those which sustain the leaves he calls *Petiolus*, and those which sustain the fruit, *Pedunculus*.

A Spike, *Spica*, is a part of a stalk thick set with flowers or fruits, in such a manner as to form an acute cone. See plate 1. fig. 12.

A Thyse, see *Thyrus*, differs from a spike in that the flowers or fruits are set more loosely on it, so that there are spaces visible between them.

A Panicle, *Panicula*, is a stalk diffused into several pedicles sustaining the flowers or fruits. See Plate 1. fig. 11.

An Umbel, *Umbella*, is the extremity of a stalk or branch, divided into several pedicles or rays, beginning from the same point, and opening in such a manner as to form an inverted cone. See plate 1. fig. 13. When the pedicles (*a*), into which the stalk is divided, are subdivided into others of the same form, upon which the flowers or fruits are disposed (*b*). The

first order (*a*) is called rays, the second (*b*) Pedicles. That umbel which consists of one pedicle only is called a simple umbel. See fig. 15. plate 1. That which is composed both of rays and pedicles, is called a compound umbel, as fig. 13.

A Corymbus differs from an umbel, in that the rays or pedicles are disposed in such a manner, as to form a sphere. See plate 1. fig. 14.

A twining stalk, *caulis volubilis*, is one which twists about any prop or tree without the help of tendrils.

A climbing Stalk, *Caulis scandens*, is that which fastens itself to any prop or neighbouring support by the help of tendrils.

A creeping Stalk, *Caulis repens*, is that which lies on the ground, and propagates itself by emitting roots at the joints.

A trailing, or procumbent stalk, *Caulis procumbens*, is that which lies on the ground unless it is supported, but does not emit roots.

A Tendril, *Capreolus* or *Clavicula*, is a part of a stalk, or rather a branch from the side of a stalk, placed opposite to the leaf, which curls and lays hold on any adjacent body, and thereby supports the stalk, as in the Vine, &c.

A Fruit, *Fructus*, is that part of a plant which contains the seed with its covering. Of this there are many different forms.

A Cone, *Conus*, is a dry seed-vessel, consisting of several ligneous parts, adhering closely together, and separating when ripe. Of this there are several sorts which differ in their form and texture, as in plate 2. fig. 1. is a cone of the Pineaster, whose ligneous scales end in sharp protuberances, which open by the warmth of the sun in the spring, and easily emit the seeds. Fig. 2. plate 2. shews the cone of the Cedar of Libanus, whose scales are smooth, lying close over each other, and drop off, leaving the middle column on the branches. Fig. 3. plate 2. exhibits a cone of the Fir-tree, whose scales are smooth, and the form oblong. Fig. 4, 5. plate 2. shews the cone of the Cypress, which is of an irregular spherical form, and the scales separate, emitting the seeds from between them. Fig. 6. plate 2. represents the cone of the Pine-tree, whose scales terminate in blunt protuberances.

Dry Seed-vessels, according to the number of cells into which they are divided, are called Unicapsular, Bicapsular, Quinquecapsular, &c. See plate 2. fig. 8, 9.

An Apple, *Pomum*, is generally understood to be a fleshy fruit inclosing several hard seeds in the center; but it is very difficult to know what the ancients meant by the title Pomum, for this title is frequently used in their writings to express things of different forms, therefore this epithet should be only applied to those fruits which are umbilicated, and contain many seeds. See fig. 11, 12. plate 2.

b

Acini

An EXPLANATION of the Technical Terms of BOTANY.

- Acini is by some supposed to be the berries of Grapes and Currants, but is used in a more extensive sense by most of the writers on botany, who stile the small protuberances of Mulberries, Strawberries, &c. fig. 7. plate 2. Acini.
- A Cluster, *Racemus*, is a stalk divided or branched into several pedicles, sustaining the flowers or fruits thick set together in an oblong form. See fig. 12. plate 2. The first of these conditions distinguishes it from a spike, the last from a panicle.
- A Pod, *Siliqua*, is a long membranaceous seed-vessel, either flat or round, containing one or two rows of seeds. See fig. 13, 14. plate 2. Some of these are jointed, each of the swellings containing one seed, as is shewn, fig. 15. plate 2.
- The Seeds of Corn and Grass are called Grains, *Grana*. The leaf which covers the grain is called Chaff, *Gluma*, fig. 16. plate 2. *a* The Beard, *Arista*. *b* is a small needle proceeding from the chaff. The chaff which has no beard is called naked.
- A Plum, *Prunum*, is a fleshy vessel inclosing a hard brittle shell, in which is one or two seeds.
- A Nut, *Nux*, is a seed covered with a hard, dry, brittle shell.
- A Flower, *Flos*, is the organs of generation of both sexes, adhering to a common placenta, together with their common coverings, or of either sex separately, with its proper coverings, if it have any.
- Flowers are either male, female, or hermaphrodite. The male flowers have stamina and summits, but have no ovary or style. Female flowers have an ovary and style, but have no stamina or summits. Hermaphrodite flowers have both organs of generation.
- The Ovary, *Ovarium*, or *Germen*, according to Linnæus, is the rudiment of the fruit. See *a*, fig. 13. plate 3. and so is properly the female organ of generation.
- The Style, *Stylus*, is a body accompanying the ovary, either arising from the top of it. See *b* fig. 13. plate 3. or standing as an axis in the middle with the embryos of the seeds round it, fig. 12. plate 3. and *c* is the stigma.
- The Empalement, *Calyx*, is generally understood to mean, those less tender leaves, which cover the other parts of the flower. See fig. 11. *a*, plate 3. These, according to Mr. Ray, are of an herbaceous colour.
- The Petals, *Petala*, are those tender fine-coloured leaves, which are the most conspicuous parts of a flower. See fig. 11. *b*, plate 3.
- The Stamina or Filaments, according to Linnæus, which some call Chives, are those slender threads which generally surround the style. See *c*, fig. 11. plate 3.
- The Summits, or Apices, which Linnæus calls *Anthera*, are those bodies which contain the farina fecundans, or prolific powder, analagous to the male sperm in animals; these generally terminate the summits. See *d*, fig. 11. plate 3.
- Flowers, according to the number of their petals, are called monopetalous, dipetalous, tripetalous, tetrapetalous, &c.
- A regular monopetalous flower is that in which the petal is not at all divided. See fig. 1. plate 3. or if divided, the segments are equal, as in fig. 2. plate 3.
- An irregular monopetalous flower, is that in which the parts of the petal are unequal, as in fig. 3. plate 3. these Dr. Linnæus calls ringent flowers. Mr. Ray, Tournefort, and others, call all those monopetalous flowers, whose petals are connected at their base, and fall off without separating; but Dr. Linnæus calls them tetrapetalous or pentapetalous, when the petal is divided into so many parts near the bottom.
- A regular polypetalous flower, is when the petals are equal in size, and agree in position, as in fig. 3. plate 3.
- An irregular polypetalous flower is when the petals do not agree together in figure and position. See fig. 9, 10. plate 3.
- A labiated, or Lip-flower, *Flos labiatus*, is an irregular monopetalous flower, divided usually into two lips, as in fig. 6. plate 3. The upper lip *a*, is called the Crest, *Galea*, and the under one *b*, the Beard, *Barba*. Sometimes the crest is wanting, as in fig. 4. plate 3. and then the style and stamina supply its place. This is by some called an unlabiated flower.
- A papilionaceous Flower, *Flos papilionaceus*, in some measure resembles a butterfly with its wings extended. See fig. 5, 7. plate 3. It always consists of these four parts: the standard, *Vexillum*, *a*, which is a large segment or petal; the two Wings, *Alæ*, *b*, which compose the sides; and the Keel, *Carina*, *c*, which is a concave petal or segment, resembling the lower part of a boat; the keel is sometimes of one petal or segment and entire; sometimes it consists of two petals or segments adhering pretty closely together.
- A Floret, *Flosculus*, is a little tube expanded at the top, usually into five segments. See fig. 17, 20. plate 3. and sitting upon the embryo of a single seed *a*; from the inner part of the floret arise five stamina *b*, which uniting together form a sheath *c*; from the embryo of the seed *a*, arises a style *d*, which passes through the sheath *c*, to which it is connected, and is terminated by a bifid stigma which is generally reflexed, *e*. These are hermaphrodite.
- A Semifloret, *Semiflosculus*, is tubulous at the base, and afterwards expanded in form of a tongue. See fig. 18. plate 3. These generally form the rays or compound flowers, and are female.
- A compound Flower, *Flos compositus*, is that which is composed either of florets, fig. 19. plate 3. or semiflorets, fig. 15, plate 3. or both together, fig. 16. and fig. 20.
- A Disk, *Discus*, is an aggregate of florets forming, as it were, a plain surface, as in fig. 19. plate 3. Such flowers are called discous flowers.
- A Ray, *Radius*, is several semiflorets set round a disk. See fig. 16. *a*, plate 3. in form of a radiant star. Such flowers are called radiated discous flowers; those which have no such ray, are called naked discous, as fig. 19. plate 3.
- A headed flower, *Flos capitatus*, is that which is composed of florets and semiflorets collected into a roundish head, and are all inclosed in one common scaly empalement, as in fig. 14. plate 3.
- A whorled Flower, *Flos verticillatus*, is when the flowers are collected in whorls round the stalks at the base of the leaves, as in fig. 20. plate 3.
- A Moss Flower, which rises on a slender foot-stalk from the plant, fig. 27. plate 3. with the head (or *Capitulum*), fig. 28. and the cover (or *Calyptra*) which opens and falls off when the seeds are ripe.
- A Cone cut through the middle longitudinally to represent how the seeds are lodged between the scales. See fig. 22. plate 3.
- Fig. 24. plate 3. shews the parts of a flower, *a* is the empalement, *b* the germen, *c* the style, *d* the stigma, *e* the stamina, *f* the summit, and *g* the same entire.
- Fig. 21. plate 3. shews a flower with several nectariums which sit close to the germen *a*.
- Fig. 25. *a* shews a germen, *b* a style, and *c* a stigma.
- Fig. 26. shews a grain of farina fecundans magnified.

Different Structures of flowers.

Plate 3.

Plate 4.

P L A T E IV.

Contain the figures which explain the System of Dr. Linnæus, who classes the plants by the number of stamina in their flowers.

- F**IG. 1. shews a flower with one stamina and one style, which he titles *Monandria Monogynia*.
 Fig. 2. shews a flower with two stamina and one style, which he titles *Diandria Monogynia*.
 Fig. 3. shews a flower with three stamina and one style, which he titles *Triandria Monogynia*.
 Fig. 4. shews a flower with four stamina and one style, which he titles *Tetrandria Monogynia*.
 Fig. 5. shews a flower with five stamina and one style, which he titles *Pentandria Monogynia*.
 Fig. 6. shews a flower with five stamina and two styles, which he titles *Pentandria Digynia*.
 Fig. 7. shews a flower with six stamina and one style, which he titles *Hexandria Monogynia*.
 Fig. 8. shews a flower with six stamina and three styles, which he titles *Hexandria Trigynia*.
 Fig. 9. shews a flower with seven stamina and one style, which he titles *Heptandria Digynia*.
 Fig. 10. shews a flower with eight stamina and one style, which he titles *Octandria Digynia*.
 Fig. 11. shews a flower with nine stamina and one style, which he titles *Enneandria Monogynia*.
 Fig. 12. shews a flower with ten stamina and one style, which he titles *Decandria Monogynia*.
 Fig. 13. shews a flower with twelve stamina and one style, which he titles *Dodecandria Monogynia*.
 Fig. 14. shews a flower with more than twelve stamina, but less than twenty, and these arise either from the petals or the empalement, and with one style, which he titles *Icosandria Monogynia*.
 Fig. 15. shews a flower with a great number of stamina and one style, which he titles *Polyandria Monogynia*.
 Fig. 16. shews a flower with two long, and two shorter stamina, and one style, which he titles *Didynamia*.
 Fig. 17. shews a flower with four long and two shorter stamina, and one style, which he titles *Tetradynamia*.
 Fig. 18. shews a flower with five stamina, which are connected with the style in one body, which he titles *Monadelphia Pentandria*.
 Fig. 19. shews a flower with ten stamina and one style, which are joined at the base into one body, which he titles *Monadelphia Decandria*.
 Fig. 20. shews a flower with many stamina joined in one body, with a many-pointed style, which he titles *Monadelphia Polyandria*.
 Fig. 21. shews a flower with six stamina joined in two bodies, which he titles *Diadelphia Hexandria*.
 Fig. 22. shews a flower with ten stamina, nine of which are joined together at their base, and the other is separated, with one style. This he titles *Diadelphia Decandria*.
 Fig. 23. shews a flower with many stamina, which are connected at their base into several clusters or bunches, which he titles *Polyadelphia Polyandria*.
 Fig. 24. shews a single floret of a compound flower. These which are hermaphrodite have five stamina and one style, which are connected at their base. This class he titles *Syngenesia*.
 Fig. 25. shews a flower whose stamina are connected with, and seem to proceed from, the style, which is divided into two parts. This he titles *Gynandria*.
 Fig. 26. shews a flower of the sixteenth class, which is of a different figure from those before represented. The stamina of this stand round the column formed by the style.
 Fig. 27. shews a floret of the compound flowers sitting upon the germen or embryo of the seed, with the two reflexed stigmas on the top of the style.

T H E

GARDENERS DICTIONARY.

A B I

BEL E-tree. See **POPULUS**.
ABIES; the Fir-tree.

The name is derived from *abeo*, to extend or advance. Others say, it is derived from *abeo*, to go away, because the bark splits, and, as it were, falls away, or is broke off easily.

The **CHARACTERS** are,
The male flowers are dis-

posed in a loose bunch, having no corolla, but many stamina, joined in form of a column at their base, but separate above, having erect summits. The female flowers are collected in an oblong cone, each scale including two, which have no corolla, a small germen with a single stigma. These are succeeded by membranaceous winged seeds.

Dr. Linnæus, professor of botany at Upsal, whose system is generally followed at present, ranges this genus in the ninth section of his twenty-first class of plants, which includes such as have male and female flowers, placed at distances on the same tree, whose stamina are joined together in form of a column.

To this genus he joins the Pine, Cedar, and Larch-tree, supposing them only different species of one genus; however, as there is great difference in the culture of these trees, we shall choose to continue the former method of arranging them under their different genera. It may not be amiss however to observe, that in the former editions of Linnæus's *Genera Plantarum*, these plants were ranged under the article *Abies*, but in the last edition he has thought proper to place them under *Pinus*.

The **SPECIES**, which are at present to be found in the English gardens, are,

1. **ABIES** (*Alba*) foliis subtus argenteis apice emarginatis, conis erectis. *Fir-tree whose leaves are white on their under-side, and indented at their points, commonly called Silver Fir.* *Abies taxi folio, fructu sursum spectante.* Tourn. Inst. R. H.
2. **ABIES** (*Picea*) foliis subulatis mucronatis levibus bifariam versis. *The Norway Fir, or Pitch-tree.* *Abies tenuiore folio, fructu deorsum inflexo.* Tourn. Inst. R. H.
3. **ABIES** (*Balsamea*) foliis subtus argenteis apice sub-

A B I

emarginatis bifariam versis. *The Balm of Gilead Fir.* *Abies taxi foliis, odore balsami Gileadensis.* Raii Hist. App.

4. **ABIES** (*Canadensis*) foliis linearibus obtusiusculis submembranaceis. *The Newfoundland White Spruce Fir.* *Abies foliis piceæ brevioribus, conis parvis biuncialibus laxis.* Rand.
5. **ABIES** (*Martiana*) foliis linearibus acutis, conis minimis. *The Black Spruce Fir of North America with very small cones.*
6. **ABIES** (*Americana*) foliis linearibus obtusiusculis bifariam versis conis subrotundis. *The Hemlock Spruce Fir.*

There is also another sort of Fir, which has been of late years introduced from North America, by the title of Red Spruce Fir of Newfoundland; but so far as we can judge by the young trees now growing in the English gardens, it appears to be only a variety of the Black Newfoundland Spruce Fir. There was also many years past a tree of the China Fir, growing in the garden of Mr. Morgan of Westminster, which is mentioned by Dr. Pluknet, but being in a bad situation it made little progress, the smoke of London being very hurtful to all sorts of evergreen trees; but whether it was killed in that garden, or removed to any other, I do not know, for the ground has been built upon many years.

The first and second sorts of Firs are very common in gardens and plantations of evergreen trees.

The first grows in great plenty about Strasburgh, and other parts of Germany; from whence the turpentine is brought to England. But it is supposed, that most, if not all of these were originally planted; however, the most beautiful of these trees are now growing upon mount Olympus, from whence I have received cones, which were upwards of a foot in length. These are certainly natives of the place. Dr. Tournefort, in his travels, mentions the Firs of mount Olympus as the most beautiful trees in the Levant.

The second sort, which is very common in the woods of Norway, is the tree that affords the white deals, and grows in the vallies where the soil is very deep.

There are two varieties of this species, greatly differing in the length and colour of their leaves, as also the size of their cones; one of which has been distinguished by nursery-gardeners, under the title of
A Long

Long Coned Cornish Fir. The leaves of this are whiter, and much longer than the others; the cones are also of a greater length than those of the common sort, so that by the appearance of the trees, any person might suppose them to be a distinct species. But from the seeds which were carefully taken from this sort, both varieties of plants have risen, therefore they must be only deemed varieties.

From this tree the pitch is drawn, and hence it had the title of *Picea*, or Pitch-tree.

The third sort was formerly growing in the Bishop of London's garden at Fulham; and of late years there has been a great number of the trees raised from the seeds which have been brought from America. This sort makes very little progress after eight or ten years growth; the only place in which the trees have made any figure, is at his Grace the Duke of Bedford's at Woburn-abbey in Bedfordshire.

The fourth sort is a native of North America, from whence the seeds have been brought to England, and great numbers of the plants raised. This is called by the inhabitants in America, the White Spruce Fir. It grows naturally on the mountains and higher lands, and arrives to a much greater size than most of the other sorts. Those in the gardens of the late Duke of Argyle, at Whitton near Hounslow, are by much the finest I have seen: but there must be some trees of a greater age in Devonshire, unless they have been destroyed; for in the year 1724, I received some branches of this tree full of cones, from a gentleman of that county, who had several of the trees then growing, which were of a considerable size.

The fifth sort grows naturally on moist land, in many parts of North America, but rarely arrives to the size of the fourth: however, the inhabitants of America use the branches of both indifferently in making of Spruce-beer, from whence the trees obtained the title of Spruce-trees.

From both these species of Fir, exsudes a fine clear turpentine of a strong scent, which the native Indians use to cure green wounds, and also for some internal disorders; and of late years the English physicians in North America, have likewise adopted it into their practice.

The sixth sort is also a native of America, from whence the seeds have been brought into Europe. This tree does not thrive well in any part of England, nor in many places of America; though in some particular spots I have been informed there are very large high trees now growing. It is a native of many parts of North America.

These trees are all raised from seeds taken out of their polyspermous cones. The way to get out the seeds is, by exposing the cones to a gentle fire, which will cause their squamous cells to open, and readily emit the seeds: but they should not be exposed to too great a heat, for the cones of all the Firs open much easier than those of Pines, especially those of the Silver and Balm of Gilead Firs, which, if permitted to hang late in the autumn, fall to pieces and scatter their seeds. This ought not to be done until the time of sowing them, which is best performed the latter end of March.

These plants should be all raised in a nursery, where they may be protected from the birds, otherwise they will be in danger of being destroyed when they first come up. For as they bring up the husk of the seed on the top of the plant, the birds, in picking off the husk, will break off the tops of the plants, whereby a whole bed may be lost in a few hours, if not carefully guarded from them.

The best time for sowing these seeds, is about the latter end of March, or the beginning of April, according as the season is more or less forward, on a bed of light earth, covering the seeds about half an inch deep with the same mould. If this bed be netted over to keep off the birds, it will be a sure method of preventing them from destroying the young plants at their first coming out of the ground, at which time they should likewise be screened from

the sun in the middle of the day, by covering the beds with mats, because too much sun frequently destroys the plants when they are young. In this bed the plants should remain until the following spring, when there should be a number of beds prepared in the nursery to receive the seedlings. In the beginning of April they should be transplanted into the beds, at the distance of six inches row from row, and in the rows at three inches asunder, setting them in a quincunx order. In removing these plants, they should be very carefully raised up with a trowel, so as not to break off the fibres of their roots; nor should they be kept long out of the ground. During the time they are out, their roots should be covered, to prevent the wind from drying their fibres; and in planting, the earth should be pressed close to their roots, to prevent the air from penetrating to them. If the season proves dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; the beds should also be covered with mats, to screen the plants from the sun, and drying winds, until they have taken good root; after which time they will require little farther care, than to keep them clean from weeds. In these beds the plants may remain two years, at the end of which they should be transplanted into an open spot of ground, for their roots will in that time meet quite over the beds. This ground, to which they are to be removed, should be well trenched and cleared from all noxious weeds, and made level. The beginning of April, just before the plants begin to shoot, will be a good time to remove them. In taking up the plants, great care should be taken not to tear off or injure their roots; nor should too many of the plants be taken up at one time, but rather plant them as fast as they are taken up, that they may be as little time out of the ground as possible. For the drying winds, which usually happen at this season, will greatly injure the roots of these plants, if much exposed thereto.

The distance at which they should be placed in the nursery, should be four feet row from row, and in the rows two feet asunder. This distance may by some be thought too great; but if it be considered how much their roots spread in the ground, as also that when they are planted nearer together, it will be very difficult to take up the plants again without cutting and tearing off their roots, especially if they are not all taken up clean at the same time: these considerations must have greater weight than that of the loss of a little ground, with all who have any regard to the future welfare of the plants. In planting them, it will be advisable to draw a line cross the ground, and to dig out a trench of a foot wide, into which the plants may be placed at the distance of two feet asunder. Then fill the earth into the trench, covering the roots of the plants with the finest part of it, scattering it carefully between the roots; and when the whole trench is filled in, press the earth gently down with your feet; but by no means tread it too hard, especially if the ground be strong, or apt to bind too close.

When the plants are thus planted, if the season should prove dry, they ought to be watered, in order to settle the earth to their roots; and if this be repeated three or four times, (if the season should continue dry) it will greatly promote their taking new root, and secure them from the injuries of the drying winds. In this nursery the plants may remain two or three years, according to the progress they shall have made; and during this time, the ground between the plants should be constantly kept clean from weeds, and dug between the rows every spring; in doing of which, care must be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nursery. When they are transplanted into the places where they are to remain, the necessary care to be taken is, in taking them up, not to injure or cut off their roots, and to let them be as little time out of the ground as possible;

and

and while they are out, to guard their roots from the drying winds. The surest time for removing these trees is about the beginning of April; for though they may be, and often are, removed with success at Michaelmas, yet the spring is the more sure season, especially in moist land.

Most of the kinds of Firs may be removed at the height of six or seven feet; but those of two feet high are much better to transplant, and will in a few years gain the ascendant of taller trees: I would not, therefore, advise the transplanting of these trees when they are much above two feet high, especially if they have stood in the nursery unremoved. For then their roots will have extended themselves to a distance, which must be cut in taking them out of the ground; and where great amputation is used either to the roots or branches of these trees, the quantity of turpentine which commonly issues from these wounds, will greatly weaken the trees. There is another advantage also in planting them when small, which is that of not requiring staking to secure them from being blown down by strong winds, which in tall trees is a great trouble or expence. And whoever will give themselves the trouble to observe, how much trees of two feet high exceed in growth those which are removed at a much greater height, will, I am sure, be convinced of the truth of what is here said.

The common Spruce Fir is what affords the white deals. The trees grow in the deep strong soils of Norway and Denmark; but will grow likewise in almost any soil or situation in England, provided it be not within the reach of the smoke of great cities, which is very injurious to all these sorts of trees; nor do they thrive near so well in dunged land, as in fresh uncultivated soils. The disrepute these trees have been under for some years past, has been occasioned by their being planted too close together, or too near other trees, whereby the air has been excluded from their branches, which has occasioned most of their under branches to decay; so that when viewed from the ground under their branches, they have a greater appearance of dead than living trees. But where they have been allowed a good distance, and planted in a strong fresh soil, they have had their branches quite feathered within six or eight feet of the ground, and that too in trees upward of sixty feet high; therefore should not be planted nearer than twelve feet apart, nor should they be so near, where the plantation is more than three rows deep. In this case, eighteen or twenty feet asunder will be full near enough, especially where the trees are designed to have their branches feathered near the ground, in which one of the beauties of these trees consists.

The Silver Fir requires a stronger land than the Spruce, for in dry ground they seldom make any great progress; and many times, even after they have arrived to a considerable size, are destroyed by very dry seasons, where the soil is shallow, or too dry. But when they are planted in a proper soil, they grow to a very large size, and are extremely beautiful, having the under side of their leaves white, and the upper side of a dark green colour.

This sort of Fir, however, is frequently injured by frosts, when they happen late in the spring, especially while the plants are young. For when these are planted in a warm situation, they are apt to shoot pretty early, and if any sharp frosts happen after they have pushed, the young shoots are killed; so that they lose a year's growth, and are rendered so very unsightly, that many times they have been pulled up and thrown away. In cold situations, however, where they do not begin to shoot so early, they are not subject to this disaster; and, in many such places, these trees grow to a large size, and have their beauty. I have sometimes seen some fine trees of this sort of Fir, which grew upon natural bogs, where, by extending their roots, they had drained the ground to a considerable distance round them. There were some trees of this kind lately growing in England, upwards of ninety feet high.

The method of raising the other sorts of Firs.

About the latter end of March, or the beginning of April (according to the forwardness of the season, by which every person must be guided) prepare a very moderate bed, in length proportional to the quantity of seeds to be sown, and where there are frames which can be spared for this purpose, these may be placed upon the bed; but where these are wanting, the bed should be cradled over with hoops, that they may be covered with mats or canvass; then plunge the bed full of small pots, such as are commonly sold about London for four shillings and two pence per hundred. These pots should be filled with light undunged earth, and the interstices between the pots may be filled up with any other earth which is nearest to the place; then sow the seeds in these pots, covering them about half an inch with the same light earth. In drying winds the bed should be covered, to prevent the earth from drying too fast, which would prove hurtful to the seeds; nor should the seeds have too much wet, which would be equally injurious to them: therefore the earth should be but seldom watered, and it must never be given in great quantities. When there is any appearance of frost at night, the bed should also be covered. With this management the plants will appear in five or six weeks time, when they must be carefully guarded from birds, as was before directed for the common sorts, and also screened from the sun in the middle of the day; but they must now have fresh air admitted to them at all times when the weather will permit. They may also be allowed to receive any gentle showers of rain, but they should not have too great plenty of moisture, which will frequently rot the young plants, and cause them to drop. Upon the judicious care of this, depends the whole success; for I have frequently seen great numbers of these plants destroyed in one day, by being either too much exposed to the sun, or from having too much wet.

It may, perhaps, seem strange to many, that I should direct the sowing the seeds of these trees which are so very hardy upon a hot-bed; but from many trials I have always found they have succeeded much better this way than any other, for the gentle warmth of the bed will not only cause the seeds to vegetate much sooner than they would naturally do in the cold ground, but the plants will also rise much stronger, and, consequently, be in less danger of rotting in their shanks. And as the warmth of the bed is only to bring up the plants, so there should be but little dung employed in making it; for after the plants are up, they must be inured to the open air, and treated as hardily as the common sorts.

There may be others, perhaps, who will object to the directions given for sowing the seeds in such small pots, because, where there is any quantity of the seeds, it is usual to sow them in boxes, or large pots: but I can from many years experience aver, that most sorts of seeds succeed better when sown in small pots, than in boxes, or larger ones, and therefore recommend this practice.

As the seeds of the Hemlock Fir will frequently remain in the ground four or five months, the pots, in which they are sown, should not be disturbed, if the plants come not up so soon as may be expected; for unless upon stirring the ground, the seeds are found to be decayed, there may be hopes of their growing the second spring, for I have sometimes had the seeds remain a whole year in the ground, and afterwards come up very well: this caution, therefore, is given to prevent the pots from being too hastily turned out.

The plants of these sorts of Fir must be afterwards treated in the same way as the common sorts, with this difference only, that they ought to be transplanted into a more shady situation and moister soil. For while the plants are young, they will not thrive if they are much exposed to the sun, or in a dry soil; but when

when they have obtained strength, they will bear the open sun very well, and in a moist soil will make great progress; whereas in dry ground they frequently stint, and produce plenty of male flowers and cones, by the time they get to the height of four or five feet. When the branches of these trees are cut off to trim them up to have stems, it should be done gradually, never cutting more than one tier of branches in one year; for if too many wounds are made at the same time on these resinous trees, the turpentine will issue out in such quantities as to weaken and check their growth. The best time for pruning these trees is in September, at which time they abound not so much in turpentine as in the spring, and, consequently, do not bleed much. What flows out at that season, is seldom more than is necessary for covering the wounds, to prevent the wet and cold of the succeeding winter from penetrating the wounded parts. These branches should be cut close to the trunk.

ACALYPHA, three seeded Mercury. This genus of plants is by Dr. Linnæus ranged in the ninth section of his twenty-first class, which comprehends such plants as have their male flowers furnished with one set of united stamina.

The CHARACTERS are,

The male flowers are in clusters situated above the female in the same plant. These have no corolla: they have a four leaved empalement with several short stamina, which are joined at their base, having roundish summits. The female flowers have a large empalement, a three leaved cup which is permanent: they have no corolla. A roundish germen with three branching styles, and a long stigma. The cup afterwards turns to a capsule with three cells, each containing one roundish seed.

The SPECIES are,

1. ACALYPHA (*Virginica*) involucris fœmineis cordatis incis, foliis ovato-lanceolatis petiolo longioribus. Hort. Upsal. 290. i. c. Three seeded Mercury, whose female flowers have a heart-shaped empalement, and oval spear-shaped leaves, with long foot-stalks. Mercurialis tri-coccus hermaphroditica.
2. ACALYPHA (*Virgata*) spicis fœmineis involucris cordatis ferratis; masculis aphyllis distinctis foliis lanceolato-ovatis. Amœn. Acad. 5. p. 410. Three seeded Mercury, whose female flowers have an indented heart-shaped empalement, distinct from the male.
3. ACALYPHA (*Indica*) involucris fœmineis cordatis subcrenatis, foliis ovatis petiolo brevioribus. Flor. Zeyl. 341. Mercury, whose female flowers have heart-shaped crenated empalements and oval leaves.

The first sort grows naturally in Virginia, and several other parts of North America, from whence I received the seeds. It is an annual plant, which seldom grows more than a foot high, sending out several side branches towards the bottom. The leaves are very like those of the broad leaved Pellitory of the wall, and are placed alternately, having long foot-stalks, from the alæ, or wings of the leaf. The flowers are produced in small clusters, the male always being above the female. These make but a poor appearance, and resemble those of the Pellitory so much, that at a small distance, any person might suppose them to be the same, till convinced by a nearer inspection.

If the seeds of this sort are permitted to scatter, the plants will come up in the spring, better than if sown by hand; for if they are not put into the ground in Autumn, they rarely grow the first year. All the culture this plant requires, is to keep it clear from weeds, and let it remain where it was sown, for it doth not bear removing well. It flowers in August, and the seeds ripen in October.

The second sort is a native of the warmest countries,

I received the seeds of this from Jamaica, where it grows in great plenty. This is also an annual plant, which in England seldom exceeds the former sort in its stature. The leaves of this greatly resemble those of the annual Nettle, and sting full as much when touched. It is too tender to thrive in the open air in England, therefore the seeds should be sown in pots, plunged into a hot-bed; and if the plants do not come up the first year, (which often happens) the pots should be put in shelter in winter, and the following spring plunged again into a hot-bed, which will bring up the plants. These must be transplanted into pots, and brought forward in hot-beds, otherwise they will not produce seeds ripe in England.

These plants have no beauty to recommend them, but as they are preserved in several gardens for the sake of variety, I thought it necessary to insert them here.

ACANACEOUS plants [so called from ἀκανθα, Gr. a thorn or prickle] are such as have prickly heads.

ACANTHUS [ἀκανθῶς, so called, as some say, from ἀκανθα, a thorn.] It is also called Branca Ursina, or Bear's-breech.

The CHARACTERS of this plant are,

The empalement is composed of three pair of unequal leaves. The flower is unequal, of one leaf, with a short tube, the beard, or lower lip, being large, plain, and erect. It has no upper lip. The stamina and style occupy the place of it. These are arched and stretched out beyond the empalement. There are two long and two shorter stamina, which closely coalesce to the style, which is situated upon a roundish germen, and afterwards become an oval capsule, having two cells, each containing one fleshy smooth oblong seed.

This genus of plants is by Dr. Linnæus ranged in the second section of his fourteenth class, intitled Didynamia Angiospermia, from the flowers having two long, and two shorter stamina, and the seeds growing in a cover.

The SPECIES are,

1. ACANTHUS (*Mollis*) foliis sinuatis inermibus. Hort. Cliff. The common, or smooth garden Bear's-breech. Acanthus Sativus vel Mollis Virgilii. C. B.
2. ACANTHUS (*Nigra*) foliis sinuatis inermibus glabris lucide virens; Portugal Bear's-breech, with smooth sinuated leaves of a lucid green colour. Acanthus Lusitanicus amplissimo folio lucido. Juss.
3. ACANTHUS (*Discoloris*) foliis lanceolatis integerrimis margine spinosis. Gron. Ov. Middle Bear's-breech, with intire leaves, having spines on their borders.
4. ACANTHUS (*Spinosus*) foliis pinnatifidis spinosis. Hort. Cliff. 326. Prickly Bear's-breech. Acanthus aculeatus. C. B. P. 383.
5. ACANTHUS (*Ilicifolius*) foliis repandis dentato-spinosis, caule fruticoso aculeato. Osb. it. 92. Shrubby Bear's-breech; with prickly leaves like Holly. Acanthus malabarius, agrifolii folio. Pet. sic. 10.

The first sort is what is used in medicine, and is supposed to be the Mollis Acanthus of Virgil. The leaves of this plant are cut upon the capitals of Corinthian pillars.

Various have been the disputes among the learned about the plant, which is mentioned under this title by Virgil, who have given so many different characters to it, that no plant yet known will agree with them all. Many, therefore, have been of opinion, that there were two sorts of the Acanthus, one of them a tree, and the other an herb. The tree is supposed to be the Egyptian Acacia, and the plant the first sort here mentioned; but there yet remains a difficulty with regard to some of the epithets applied to that plant, as first, where it is mentioned to be an evergreen berry-bearing plant. *Baccas semper frondentis Acanthi*. As to its being evergreen, that may be easily conceived of our Acanthus, in the warm climate of Italy; for in England, where the plants grow in a warm situation, they are seldom destitute of leaves more than six weeks, unless the winter proves very severe. We may also suppose, that the fleshy oval seed-vessels of this plant might be taken for berries. But then with regard to its being a twining plant, *flexi-*

tacuisse

tacuisse vimen acanthi, it will by no means agree with this, or the Egyptian Acacia. However, as the botanists in general have agreed that the plant here mentioned is the Acanthus of Virgil, and there being several entire columns of the Corinthian order yet remaining at Rome, upon whose capitals the leaves of this plant are so well expressed, as not to admit of any doubt of their being designed from our Acanthus, and these columns being as antient as the time of Vitruvius, there can be no doubt that this is the plant from whose leaves Callimachus, a famous architect, composed the capitals of the Corinthian pillars.

The second sort was discovered in Portugal by Dr. Bernard de Jussieu, demonstrator of plants in the royal garden at Paris, from whom I received the seeds in 1725, which succeeded in the Chelsea garden, and frequently perfects seeds there; which being sown, constantly produce the same plants as the parent, and therefore must be a distinct species.

The third sort is at present very rare in England; it grows naturally in the east, and is by Dr. Linnæus supposed to be the Acanthus of Dioscorides, but with what certainty I cannot determine. This sort is not so hardy as either of the two former, and requires shelter in the winter; therefore the plants, while young, should be kept in pots, and placed under a common frame during the winter season; where they may enjoy the open air in mild weather, but screened from hard frosts. When the plants have acquired strength, some of them may be turned out of the pots, and planted in a border near a south wall, and in hard frosts if they are covered with mats or hand-glasses, they may be secured, and these plants will more certainly flower than those in the pots.

The leaves of the fourth sort are deeply jagged, in very regular order, and each segment is terminated with a sharp spine, as are also the foot-stalks of the leaves, and the empalement of the flower, which renders it troublesome to handle either of them.

The fifth sort grows naturally in both Indies; I received it from the Spanish West-Indies. There is a good figure of this plant in Plukner's Phytographia, tab. 261, fig. 4. under the following title, *Frutex Indicus spinosus, foliis Agrifolii siliqua geminata brevi*. This is a shrub which rises about four feet high, is divided into many branches, garnished with leaves, very like those of the common Holly, both in size and shape, and are armed with spines in the same manner; the flowers come out singly, which are white, and shaped like those of the common Acanthus, but smaller. After the flower is past, the germen becomes an oval bicapsular vessel, having one oblong seed in each cell. This shrub is evergreen, but is too tender to thrive out of a stove in England, and can only be propagated by seeds, which do not ripen in Europe. The other sorts are lasting plants, which may be propagated either by seeds, or parting of their roots; if by the former method, the seeds should be sown in a light dry soil, towards the end of March: if the season proves favourable, the plants will appear in May, and all the culture they require, is to keep them clean from weeds, and where the plants are too close, to thin them, so as to leave them about six inches asunder, which will be room enough for them to grow till autumn, when they should be transplanted where they are designed to remain. The first, second, and third sorts, being tenderer than the others, ought to be planted in a warm border near a wall; and as these do not multiply so fast by their roots, so they do not require more room than three feet; but the fourth sort spreads its roots to a great distance, therefore must have more than twice that room. This being hardy in respect to cold, may be planted between shrubs, to fill up vacant spaces, where it will thrive fast enough, provided the ground be light, and not over wet, and when the plants are in flower, will make an agreeable variety. If this sort is propagated by its root, it may be performed either in spring or autumn; but the three first must only be removed in the spring, for if

they are transplanted in the autumn, and the following winter prove cold, they will be in danger of being destroyed.

These plants take root very deep in the ground; so that when they are planted in wet ground, their roots will rot in winter: I have frequently traced them more than four feet, therefore they should not be removed after they have been growing long in a place, but the side shoots may be annually taken off, especially from the creeping kinds, otherwise they will spread so far, as to over-bear any of their neighbouring plants or shrubs. When the sorts with creeping roots are once established in a garden, they are with difficulty eradicated, for every root which may happen to be left, will shoot again, so as to become troublesome.

ACARNA. See CNICUS.

ACAULIS, or ACAULOS [of *a neg.* and *caulis* a stalk or stem; i. e. without stalk;] a plant is said to be *acaulis*, or without stalk, whose flower rests on the ground, having no visible stalk.

ACER [so called according to Vossius, from *acris*, L. because of the very great hardness of its wood.] The Maple-tree.

The CHARACTERS of this tree are,

The empalement of the flower is *monopetalus*, coloured, and cut into five sharp segments at the brim, and is permanent. The corolla is composed of five oval petals which spread open, and are larger than the empalement. It hath eight short awl-shaped stamens crowned by simple summits. The germen is compressed, and immersed in the large perforated receptacle. The style is slender. It hath two acuminate stigma which are reflexed. The capsules are two, joined at their base; they are roundish, each being terminated by a large wing, inclosing one roundish seed in each.

This is ranged by Dr. Linnæus, in his twenty-third class of plants, entitled *Polygamia Monœcia*.

The SPECIES are,

1. ACER (*Pseudo Platanus*) foliis quinquelobis inæqualiter serratis floribus racemosis. Lin. Sp. Plant. 1054. The greater Maple, falsely called *Platanus*. Acer majus multis falso *platanus*. J. B. The Sycamore-tree.
2. ACER (*Campestre*) foliis lobatis obtusis emarginatis. Lin. Sp. Plant. 1055. The small, or common Maple. Acer *campestre* & minus. C. B. P. 431. By the French, *Petit érable des bois*.
3. ACER (*Negundo*) foliis compositis floribus racemosis. Hort. 144. The Virginia Ash-leaved Maple. Acer maximum foliis trifidis vel quinquefidis Virginianum. Pluk. Phyt.
4. ACER (*Platanoides*) foliis quinquelobis acuminatis acutè dentatis glabris floribus corymbosis. Lin. Flor. Suec. 303. The Norway Maple with Plane-tree leaves. Acer *platanoides*. Munt. Phyt.
5. ACER (*Rubrum*) foliis quinquelobis subdentatis subtus glaucis pedunculis simplicissimis aggregatis. Lin. Sp. Plant. 1055. The scarlet flowering Maple of Virginia. Acer Virginianum folio majore subtus argenteo supra viridi splendente. Pluk. Alm. 7.
6. ACER (*Saccharinum*) foliis quinquepartito-palmatis acuminato dentatis. Lin. Sp. Plant 1055. The American Sugar Maple.
7. ACER (*Pennsylvanicum*) foliis trilobis acuminatis serratis floribus racemosis. Lin. Sp. Plant. 1055. The Mountain Maple of America.
8. ACER (*Opalus*) foliis lobatis, minimè incisis fructu racemoso. The Italian Maple, commonly called *Opalus*. Acer major folio rotundiore minùs laciniato & *opalus* Italicorum. Raii Hist.
9. ACER (*Montspesulanum*) foliis trilobis integerrimis. Prod. Leyd. 459. The Montpellier Maple. Acer trifolium. C. B. P. 431.
10. ACER (*Cretica*) foliis trilobis integerrimis subtus pubescentibus. Cretan Maple with three entire lobes to the leaves, which are somewhat hairy on their under-side.

These trees are easily propagated by sowing their seeds, which should be done soon after they are ripe, in a bed of common earth, covering them about half an inch thick with light mould. The spring following they will appear above ground, and, if kept clear from weeds, some of the sorts will grow above a foot high

the first summer. The autumn following (if they are close in the seed-bed) it will be proper to transplant them into a nursery, in rows at three feet distance, and two feet asunder in the rows; in which place they may remain three or four years, by which time they will be large enough to plant out for good.

If the seeds of any of the sorts of Maple are kept out of the ground till spring, they rarely come up the same year, and many times do not grow; so that the surest method of raising them is, to sow the seeds as soon as possible when they are ripe; and, if the seeds are to be transported to any distance, it will be proper to put them up in sand, or earth, whereby their growing quality will be preserved.

The first and fourth sorts are very proper to make plantations near the sea, or to shelter such plantations of trees as are too nearly situated thereto. For both these sorts thrive, and resist the spray, which is usually blown from the sea, better than most other trees do. The variegated sort is also raised from seeds of the same kind; and most of the plants so raised, will be as finely striped as the old plant from whence the seeds were taken, which is not common to many other variegated plants.

The common Maple is too well known to need any particular account, it growing, very frequently, in hedge-rows in most parts of England. It is raised in the same manner with the former.

The Virginian flowering Maple was raised from seeds, which were brought from Virginia many years since by Mr. John Tradescant, in his garden at South Lambeth, near Vauxhall, and since, in the gardens of the Bishop of London, at Fulham, where the trees have flowered for several years, and produced ripe seeds, from which several trees have been raised. It may be also propagated by laying down the young branches early in the spring, giving them a little slit at a joint, by which means they will have taken sufficient root in two years, to be transplanted elsewhere. They require a situation a little defended from the north-east winds, especially while young; and delight in a moist light soil, in which they thrive much better than in a dry ground, and will produce more flowers, and better seeds. This tree commonly flowers in the beginning of April, and the seeds are ripe in five or six weeks after, at which time they should be sowed; for they are very apt to perish, if kept long out of the ground. There is another variety of the flowering Maple, which was sent from America to Sir Charles Wager, and flourished several years in his garden at Parsons-green, near Fulham. This is by the gardeners titled Sir Charles Wager's flowering Maple. The flowers of this kind come out in large clusters, and surround the younger branches, so as to appear at a small distance covered with them. It is now become pretty common in some of the nurseries near London, so that the former sort is not so much esteemed, being less beautiful; but it is doubtful if they are distinct species.

The Ash-leaved Maple is a very strong shooting tree, and is, in Virginia, one of the largest trees of this kind. It must be planted in places not too much exposed to violent winds, being subject to split thereby. This tree ripens seeds very well in England, by which means it is easily propagated, or by cuttings planted in autumn.

The Norway Maple has a milky sharp juice, so that few insects care to prey thereon, by which means the leaves are seldom eaten or defaced; and being smooth, and of a shining green, they have a much better appearance than those of the Sycamore; and in the spring, when the flowers are out, have great beauty. This tree is also raised by seeds, of which it affords great quantities, which rise and grow from the scattered seeds as well as the common sort; it will also grow from cuttings, if they are planted in the autumn.

The variegated kind may also be propagated by inoculating a bud of the striped kind into one of the plain sort, though I am not at present sure whether it will take upon any other sort of Maple, not having

made the experiment; but I believe it can scarce fail. Most, if not all the other sorts of Maples, take very well upon each other.

The American Sugar Maple has some resemblance to the Norway, when the plants are young; but as they grow up the leaves are more deeply divided, and their surfaces less smooth, so that they are then easily distinguished. From this tree the inhabitants of North America make a very good sort of sugar, in large quantities, by tapping the trees early in the spring, and boiling the juice, which drawn out till the faeces subside, is the sugar; but I am of opinion, that the people make sugar from more than one sort of Maple in America, for I have found that the Ash-leaved Maple abounds with a saccharine juice, in full as great plenty as any other sort. Mr. Ray and Dr. Lister, prepared a tolerable good sort of sugar from our greater Maple, by tapping some of the trees in their bleeding season; and I have observed, upon cutting off branches from the scarlet Maple in February, a great quantity of a very sweet juice hath flowed out for several days together.

The eighth sort of Maple is very common in most parts of Italy, but particularly about Rome, where it is one of the largest trees of that country, and is esteemed for the size of the leaves, which are large, affording a great shade; so that these trees are frequently planted by the sides of roads, and near habitations. In England this tree is very rarely to be met with, though it is hardy enough to bear the open air; but as the seeds have not been brought over to England till lately, there are no large plants in the English gardens at present.

The ninth sort is common in the south of France and Italy; the leaves of this resemble those of the common Maple, but are of a much thicker substance, and not so large, but are of a shining green colour. They continue in verdure very late in the autumn, which renders the trees more valuable. At present, this sort is not common in England. I raised several plants from seeds, some of which have for several years produced good seeds in the Chelsea garden, where from the scattered seeds the plants come up annually in plenty.

The tenth sort hath some resemblance to the ninth. The leaves of this sort are of a much thinner texture, and their foot-stalks are covered with a soft hairy down, whereas those of the other are smooth and stiff. This sort grows naturally in the Levant.

Most of the sorts of Maple which come from America, are very impatient of heat while young; their seeds therefore should be sown in a sheltered situation, for if the plants are exposed to the full sun but one day, when they first appear, few of them will survive it; but especially the Sugar Maple, of which sort I constantly lost most of the plants, till I had the precaution to place the pots, in which the seeds were sown, entirely in the shade; for no sooner are they exposed to the sun, but they are immediately attacked by insects, which in one day will devour their seed leaves, after which the plants suddenly drop to the ground. This precaution therefore is necessary to be observed, in raising most of the sorts of Maple from seeds.

The timber of the common Maple is far superior to the Beech for all uses of the turner, particularly dishes, cups, trenchers, and bowls; and when it abounds with knots (as it very often doth), it is highly esteemed by the joiners for inlayings, &c. and also for the lightness of the wood, is often employed by those that make musical instruments; and for the whiteness of its wood, it was formerly in great request for tables, &c.

ACETOSA [of *acetosus*, L. eager, sour.] The Sorrels are by Dr. Linnæus joined to the genus of Dock, under the title of *RUMEX*; but as all the known species of Sorrel, have male flowers growing upon distinct roots from the female, therefore by his method should be ranged in his twenty-second class titled *Dicœcia*; therefore I have taken the liberty to separate these from the Docks, rather to preserve their old title,

as the plants have been long used both in the kitchen and shops.

The CHARACTERS are,

It hath male and female flowers in different plants; the male flowers have a three leaved empalement, in which are included six stamina, crowned with flat oblong summits, but have no corolla: the female flowers have also a three leaved empalement, in the center of which is situated a three cornered germen, supporting a trifid stylus. The germen afterward turns to a triangular seed.

The SPECIES are,

1. ACETOSA (*Pratensis*) foliis sagittatis inferioribus pediculis caulinis sessilibus. Common or Meadow Sorrel. *Acetosa pratensis*. C. B. P. 114.
2. ACETOSA (*Acetosella*) foliis lanceolato-hastatis radice repente. Common Sheep's Sorrel. *Acetosa arvensis lanceolata*. C. B. P. 114.
3. ACETOSA (*Scutatus*) foliis cordato hastatis radice repente. Round leaved or French Sorrel. *Acetosa rotundifolia hortensis*. C. B. P. 114.
4. ACETOSA (*Digynus*) humilis repens folio rotundo emarginato. Low creeping Sorrel with a round indented leaf. *Acetosa rotundifolia repens Eboracensis folio in medio deliquium patiente*. Mor. Hist.
5. ACETOSA (*Alpina*) foliis cordatis acuminatis amplexicaulibus. Alpine Sorrel, with heart-shaped pointed leaves embracing the stalks. *Acetosa montana lato ari rotundo folio*. Bocc. Mus.
6. ACETOSA (*Lunaria*) foliis subcordatis, caule arboreo. Sorrel-tree with roundish heart-shaped leaves. *Acetosa arborescens, subrotundo folio*. Pluk. Alm. 8.
7. ACETOSA (*Rosea*) foliis erosis, valvulae alterius ala maxima membranacea declinata. Sorrel from Egypt with bitten leaves, and large membranaceous valves declining. *Acetosa Aegyptia rosea seminis involucro*. Shaw. Pl. Afr.
8. ACETOSA (*Sterilis*) foliis oblongis pedunculis brevissimis raro florens. Northern barren Sorrel. This is the *Acetosa Muscovitica sterilis*. Mor. Hist.

The first of these sorts, though but small in the fields, yet, when sown in gardens, will produce fair large leaves; this is commonly cultivated in gardens. It must be sown early in the spring, in a shady, moist border; and if the plants are afterward removed into another shady border, at the distance of four or six inches square, they will produce larger leaves, and continue longer. This is the common Sorrel used in medicine; but the Northern barren Sorrel is preferred to it in the kitchen-garden, because it rarely runs to seed, but is increased by parting the roots either in spring or autumn, and is fit for use all the year.

The round leaved (or French) Sorrel, is a more grateful acid, so by many persons is preferred to the other two sorts for kitchen use; this is also a medicinal plant, and should not be wanting in any good garden: it is a great runner at the root, by which means it is easily propagated, and the roots planted at the distance of two feet square at least: it will agree better with an open situation than the other two sorts. And if the flower-stems and rambling branches are cut off in the beginning of July, the roots will soon put out new leaves, which will be tender and much better for kitchen uses, than the older leaves; so that by cutting down the shoots of some plants at different times, there will always be a supply of young leaves, which is the only part of the plant used in the kitchen. And this sort is much preferable to the common Sorrel for soups, so many persons have of late years cultivated it in their gardens; since the use of Sorrel has been greatly increased in England, by the introduction of French cookery, it being an ingredient in many of their sauces and soups. Inasmuch that about Paris, Sorrel is cultivated in as great quantity as almost any other esculent plant.

The Sheep's Sorrel is a common weed in most parts of England; growing upon dry banks and in gravelly soils in great plenty; for as it propagates very fast by its creeping roots, so wherever it once gets possession in the ground, it soon multiplies. This is rarely admitted to have a place in gardens, but as it has long

been continued in the Dispensaries as a medicinal plant, so it is here inserted.

The low creeping Northern Sorrel, is preserved in many gardens for the sake of variety, but has not been used in the kitchen. This sort grows wild in most of the northern counties, as also in Wales. I have seen it growing in great plenty in Yorkshire and Westmoreland. The leaves of this sort have very short footstalks, and are indented at both ends. These grow near to the ground, and the flower-stems rarely rise above six inches high. The roots creep in the ground, whereby it multiplies exceedingly in a proper situation. As this sort grows naturally in shady moist places, so whoever is desirous to have it thrive in a garden, must plant it in a north border and in a moist soil, where it may be propagated in plenty, and be used for the same purposes as the others.

The Alpine Sorrel is full as hardy as the common, and as the leaves are much larger, so they are better for the uses of the kitchen, having as pleasant an acid taste, and being much more succulent. This may be propagated either by seeds, or parting of their roots, in the same manner as the common sort; but the plants require more room, for which reason they ought not to be nearer than a foot from each other, especially in good ground.

ACETOSELLA. See OXALIS.

ACHILLEA, Milfoil Yarrow, or Nosebleed.

The CHARACTERS are,

It hath a compound radiated flower, consisting of many tubulous florets, which are hermaphrodite, and compose the disk of the flower; the female flowers are ranged round the border; these have their corolla stretched out on one side like a tongue, which compose the rays, all included in one common scaly empalement. The hermaphrodite flowers have each five short slender stamina, accompanying a small germen, which is situated in the bottom, and rests upon a downy bed; the germen afterwards becomes a single oval seed, having a down adhering to it.

The SPECIES are,

1. ACHILLEA (*Millefolium*) foliis bipinnatis nudis, laciniis linearibus dentatis. Hort. Cliff. 413. Common Yarrow, called also Milfoil, Stratiotes, and Nosebleed. Of this there is a variety with purple flowers, which is often found growing naturally in England.
2. ACHILLEA (*Santolina*) foliis setaceis dentatis, denticulis subintegris subulatis reflexis. Hort. Cliff. 412. Eastern Sneezwort with a Lavender-cotton leaf, and a large flower.
3. ACHILLEA (*Tomentosa*) foliis pinnatis hirsutis pinpis linearibus dentatis. Lin. Sp. Plant. 897. Woolly Yarrow with yellow flowers.
4. ACHILLEA (*Pubescens*) foliis pinnatis, foliolis lanceolatis incisissimis serratis subtus lanigeris. Hort. Cliff. 413. Eastern Sneezwort with hoary Tansey leaves, and the rays of the flower of a pale yellow colour.
5. ACHILLEA (*Abrotanifolia*) foliis pinnatis supra decompositis, laciniis linearibus distantibus. Flor. Leyd. Prod. 175. Tallest Eastern Yarrow, with a Wormwood leaf and yellow flowers.
6. ACHILLEA (*Clavennae*) foliis pinnatifidis planis obtusis tomentosis. Lin. Sp. Plant. 898. Broad-leaved Alpine umbelliferous Wormwood.
7. ACHILLEA (*Tanacetifolia*) foliis pinnatis foliolis linearibus lanceolatis basi sursum auctis. Flor. Leyd. Prod. 176. Eastern Sneezwort with hoary Tansey leaves, and a golden flower.
8. ACHILLEA (*Ageratum*) foliis lanceolatis obtusis acutè serratis. Hort. Cliff. 413. Commonly called Sweet Maudlin.
9. ACHILLEA (*Aegyptiaca*) foliis pinnatis foliolis obtusè lanceolatis serratis dentatis. Hort. Cliff. 413. Hoary Sneezwort with crested pinnula.
10. ACHILLEA (*Ptarmica*) foliis lanceolatis acuminatis argutè serratis. Lin. Sp. Plant. 898. Common Ptarmica or Sneezwort. Of this sort there is a variety with double flowers which is preserved in gardens.
11. ACHILLEA (*Macrophylla*) foliis pinnatis planis incisè serratis extimis majoribus coadunatis. Lin. Sp. Plant. 1265. Alpine Sneezwort with Froerfew leaves.

12. ACHILLEA

12. *ACHILLEA* (*Nana*) foliis pinnatis dentatis hirsutissimis floribus glomerato umbellatis. Lin. Sp. Plant. 2671. *Hoary Alpine Milfoil, with a specious flower.*
13. *ACHILLEA* (*Nobilis*) foliis bipinnatis, inferioribus nudis planis, superioribus obtulis tomentosis corymbis convexis confertissimis. Lin. Sp. 1268. *Noble or Sweet Milfoil.*

14. *ACHILLEA* (*Alpina*) foliis lanceolatis dentato-ferratis denticulatis tenuissimè ferratis. Hort. Cliff. 413. *Alpine Sneezwort with leaves deeply serrated, commonly called White Maudlin.*

The first sort here enumerated, is the common Yarrow or Milfoil, which grows naturally on banks and by the sides of foot-paths in most parts of England, so is rarely allowed a place in gardens; but being an officinal plant, it is here mentioned to introduce the others. Of this there is a variety with purple flowers, which is frequently found wild in England; but the plants seldom continue to produce purple flowers long, when they are transplanted into gardens. The Yarrow creeps greatly by its roots, and also multiplies by seeds, so that it becomes a troublesome weed, where it is permitted to grow.

The third sort is often planted in gardens for the sake of variety. This is of humble growth, seldom rising more than eight or nine inches high. The leaves are finely cut, and are very hoary; the flowers are of a bright yellow colour, and continue long in beauty. It grows naturally in the south of France, Spain, and Italy, but will live in the open air in England. It is increased by parting of the roots, the best time for which is in October.

The fourth, fifth, seventh, and ninth sorts, are natives in the islands of the Archipelago. These were introduced into France by Dr. Tournefort. The ninth sort hath very hoary leaves, which remain all the year; and the plants growing close and low, make a pretty appearance at all seasons. The flowers are produced in umbels on the top of the stalks, which are yellow; these appear in June, July, August, and September, and are of long duration, so that frequently some of them continue the greater part of the winter. This sort must have a dry soil and a warm situation, where it will endure the cold of our ordinary winters in the open air, but in very severe frost they are often destroyed; a few plants therefore ought to be sheltered under a frame in winter, to preserve the kind. It is propagated by slips, which may be taken off and planted in a shady border, any time in summer, when they will take root in about six weeks, and then may be transplanted either into pots, or the borders where they are to remain. This sort rarely perfects its seeds in England.

The fourth, fifth, and seventh sorts, are of taller growth, propagating by their roots, and ripening seeds in England, so that they may be obtained in plenty; and as they require little care to cultivate them, being hardy enough to live in the open air, they may be allowed a place in gardens, where, by their hoary leaves, they will make a pretty diversity; and their flowers continuing long, though not the most beautiful, yet make a pretty contrast when intermixed with others.

The sixth sort is a very humble plant; the foot-stalks which support the umbels of its flowers, rarely rise above six inches high. As for the flowers themselves, they are near as large as those of the common Sneezwort, white, and growing in flat umbels; these appear in June and July. The leaves of the plant have some likeness to those of the common Wormwood, and are very hoary, growing close to the ground, decaying in autumn, so that in winter they make little appearance. This species of Yarrow is propagated by parting of the roots, either in spring or autumn, and should have a dry soil, for much wet in winter will rot them. It never perfects its seeds here, and therefore can only be multiplied the other way. This sort is a native of the Alps.

The eighth sort is commonly known by the title of Sweet Maudlin in the markets; it was formerly more used in medicine than at present, so that there is scarce

any of it cultivated in the gardens for sale; and when it is asked for, the people in the markets commonly give the fourteenth sort for it, which being a very hardy plant, and easily propagated, is now generally sold for the other. For though the true Maudlin is hardy in respect to cold, yet in wet winters the roots are often killed by moisture, especially those which are in good ground; but when the plants grow out of the joints of walls, or in rubbish, they will live many years without care. There are two other varieties of this plant which are found growing naturally in Spain, one of them having longer and more compact umbels of flowers, and the other hath broader leaves and smaller flowers; but these approaching so near to the common sort in every other particular, I thought it would be needless to enumerate them as distinct species. The common Maudlin is propagated by parting of the roots, either in spring or autumn; and as it ripens seeds very well, so it may be propagated by sowing the seeds in April. It flowers in June and July, and the seeds are ripe in September.

The tenth sort is the common Sneezwort; this grows wild in the woods and other shady places, in many parts of England, so is not admitted into gardens; this creeps greatly by its roots, so as to cover a large spot of ground soon. It is sometimes used in medicine, and in the spring the young tender shoots are put into sallads, to correct the coldness of other herbs; and the roots are used for the tooth-ach, whence some have given the title of Field Pellitory to this plant. There is a variety of this with double flowers, which is preserved in gardens, and is commonly known by the title of double Maudlin. When this is planted in pots, so as to confine the roots from creeping, the stalks will grow closer together, and then they make a tolerable appearance when in flower; but where the roots have full liberty to run, the stalks grow farther distant from one another, in which case they make but an indifferent appearance. It flowers in July and August.

The fourteenth sort has some resemblance to the tenth, but the leaves are longer, deeper cut on their edges, and are of a darker green colour. This propagates fast enough by its creeping root, and is very hardy.

The eleventh and twelfth sorts are natives of the Alps, and consequently very hardy; they multiply by seeds, and also by parting of their roots, and will thrive in almost any soil, but love an open exposure. The eleventh produces many stalks which rise near three feet high, having loose branching umbels of white flowers on their top, resembling those of the common Sneezwort, but larger. The twelfth sort hath hoary leaves, and the umbels of its flowers are more compact; the stalks of this do not rise more than a foot high. Both these deserve a place in gardens.

The thirteenth sort approaches near the first, but the leaves are of a pale green, and not so long, or so much cut as those of the first; these have a strong sweet scent when bruised. It is equally hardy with the first, and therefore requires little culture.

A C H R A S. See SAPOTA.

A C H Y R A N T H E S.

The CHARACTERS are,

The empalement consists of five pointed rigid leaves which are permanent; the flower hath no petals; but in the center of the empalement is situated the pointal, having a bifid stigma, attended by five stamina, supporting small summits. The pointal afterward becomes a single roundish seed, inclosed in the empalement.

The SPECIES are,

1. *ACHYRANTHES* (*Aspera*) caule erecto, calycibus reflexis spicæ adpressis. Fl. Zeyl. 105. *Achyranthes with an upright stalk, and a reflexed flower-cup.* *Amaranthus ficulus* spicatus radice perenni. Bocc. Rar. Plant. 16. tab. 9.
2. *ACHYRANTHES* (*Indica*) caule erecto, foliis obversè ovatis undulatis floribus reflexis. *Achyranthes with an erect stalk, obverse oval waved leaves and reflexed flowers.*

3. *ACHYRANTHES*

3. *ACHYRANTHES* (*Lappacea*) caule erecto, spicâ interruptâ, floribus externè lanatis. Lin. Sp. Plant. 204. *Achyranthes with an upright stalk, a loose spike, and the outside of the flower woolly.*

4. *ACHYRANTHES* (*Lanata*) caule erecto, spicis ovatis lateralibus calycibus lanatis. Lin. Sp. Plant. 204. *Achyranthes with an erect stalk, and oval spikes of flowers produced from the wings of the leaves, which are covered with a soft down.*

The first sort hath been long in the English gardens, where it hath been preserved more for the sake of variety, than for its beauty or use. It grows near three feet high, with oblong pointed leaves; the flowers come out in long spikes from the extremity of the branches, which are composed of an empalement, with a style and five stamina, but hath no petals, so may be ranged under the class of blink flowers. The plants of this sort must be raised on a hot-bed, and when they have acquired strength, they may be transplanted into the full ground, where they will flower in July, and their seeds ripen in September. If these are kept in pots, and put into a warm green-house in winter, they will live two or three years, where persons are inclined to keep them so long. This sort grows naturally in the islands of America, and also in India and Sicily.

The seeds of the second sort I received from Malabar, which have for some years flourished at Chelsea, and annually produced ripe seeds, which have never varied from the parent plant.

The third and fourth sorts grow naturally at the Cape of Good Hope, from whence I received their seeds. These are all preserved in botanic gardens for the sake of variety, but have no great beauty to recommend them, to those who do not cultivate plants for the improvement of that science.

They may all be propagated in the same manner as the first, and will perfect their seeds the same year; but the plants of the three last sorts may be preserved through the winter if placed in a stove, for they are too tender to be kept in a green-house where there is not artificial heat.

ACINOS. See **THYMUS**.

ACINUS, or **ACINI**, by good authors is not used for the grape stone, but the grape itself, as appears from the following passage in Columella, *Cum expresseris vinacea, quæ acinis celantur.* It is commonly used for those small grains growing in bunches, after the manner of grapes, as *Ligustrum*, &c.

ACNIDA, Virginia Hemp.

This plant grows naturally in Virginia, and in some other parts of North America, but is rarely cultivated in Europe, except in some few botanic gardens, for the sake of variety. It hath male and female flowers growing upon different roots, so is near of kin to the Hemp, under which title it has been ranged by some former botanists. But as it is a plant of little beauty, and at present no use has been made of it, it is to little purpose to say more of it here.

ACONITUM, Wolfsbane, or Monkshood, [of ἀκων, or ἀκὴ, a dart, because the Barbarians used to daub their darts therewith; others of ἀκονίω, to accelerate, because it hastens death].

The **CHARACTERS** are,

The flower hath no empalement, but consists of five unequal petals, which vary in different species; the galea (or hood) is tubulous, and covers the other parts of the flower like a friar's cowl; the two lateral petals, which inclose the stamina and style are equal: these are concave and slightly indented in the middle. The two lower petals are narrow and oblong: in the bottom of the flower are placed two nectarii, upon which are situated the styles; in some there are two, in others three, and some have five: these are forked, and stretch out far beyond the stamina, which are numerous and irregular: after the flower is past, the germen become oblong seed-vessels terminated in a point, and coalescing at their base; these have but one cell, which is filled with angular rough seeds.

This genus of plants is by Dr. Linnæus ranged in the third section of his thirteenth class, entitled Polyan-

dria trigynia, from the flowers having many stamina, and three styles.

The **SPECIES** are,

1. **ACONITUM** (*Lycostonum*) foliis palmatis multifidis villosis. Lin. Sp. Plant. 532. *Yellow Wolfsbane or Monkshood, with palmated hairy leaves finely divided.* *Aconitum lycoctonum luteum.* C. B. P. 183.

2. **ACONITUM** (*Altissimum*) foliis palmatis, nervosis glabris. *Greatest yellow Wolfsbane, with nervous, smooth, palmated leaves.* *Aconitum luteum majus* ampliore caule amplioribusque foliis. Dod. p. 441.

3. **ACONITUM** (*Variegatum*) foliis multifidis laciniis semipartitis supernè latis. Hort. Cliff. 214. *Lesser Wolfsbane with blue flowers, whose under leaves are cut into many parts, and whose upper have broader segments.* *Aconitum cæruleum minus*, five napellus minor. C. B. P. 183.

4. **ACONITUM** (*Anthora*) floribus pentagynis foliorum laciniis linearibus. Lin. Sp. Plant. 532. *Wholesome Wolfsbane with yellow flowers.* *Aconitum salutarium* five anthora. C. B. P. 184.

5. **ACONITUM** (*Napellus*) foliorum laciniis linearibus supernè latioribus linea exaratis. Hort. Cliff. 214. *Wolfsbane, or Monkshood, with large blue flowers.* *Aconitum cæruleum*, five napellus. 1 C. B. P. 183.

6. **ACONITUM** (*Pyramidale*) foliis multipartitis, spicis florum longissimis sessilibus. *The common blue Monkshood, with a long spike of flowers.* *Aconitum pyramidale* multiflorum. H. R. Par.

7. **ACONITUM** (*Alpinum*) foliorum laciniis pinnatifidis flore maximo. *Large flowered Monkshood, or Wolfsbane, of a blue purple colour.* *Aconitum cæruleo purpureum* flore maximo, five napellus. 4 C. B. P. 183.

8. **ACONITUM** (*Pyrenaicum*) foliis multipartitis laciniis linearibus incumbentibus squamosis. Hort. Upsal. 152. *Yellow Pyrenean Monkshood, or Wolfsbane, with fine cut leaves.* *Aconitum Pyrenaicum luteum* foliorum segmentis sibi invicem incumbentibus. Raii Syll. 367.

9. **ACONITUM** (*Cammarum*) floribus subpentagynis, foliorum laciniis cuneiformibus incisus acutis. Lin. Sp. Plant. 751. *Monkshood with flowers, having commonly five styles, and the segments of the leaves awl-shaped.*

10. **ACONITUM** (*Orientale*) elatius, foliis palmatis flore magno albo. *Eastern Monkshood, with a tall stalk and a large white flower.* *Aconitum lycoctonum orientale* flore magno albo. Tourn. Cor.

The sixth sort is the most common in the English gardens; this is cultivated for the beauty of its long spike of blue flowers, which are brought to the markets in London, towards the end of May, when it commonly flowers; so that these being intermixed with the Guelder Roses and other flowers of the same season, make an agreeable variety, when properly blended, to adorn halls and other apartments. But as most of the species of Monkshood are a deadly poison, not only to men but to brutes also, they ought not therefore to be admitted into places where children or ignorant persons frequent, lest by smelling to these flowers, they should draw some of the farina into their nostrils, which may prove very hurtful to them, as I can from experience assert for fact. We have an account of a man who was poisoned in the year 1732, by eating some of this plant, which by an unskilful person was put into a salad instead of Celery. This is particularly mentioned in the Transactions of the Royal Society, N^o 432. Dodonæus also relates a story of the bad effects of one species of Monkshood, which was recent in his time. Some unskilful persons had gathered the young shoots of the blue Monkshood to eat in a salad, and all that eat of them were seized with terrible symptoms, and soon died. Dr. Turner also mentions, that some Frenchmen at Antwerp eat the shoots of this plant for those of Masterwort, and all of them died in two days, except two players who threw them up by vomit. I have known persons who by smelling to the flowers, have been seized with swooning fits, and have lost their sight for two or three days.

The fourth sort is that which is made use of in medicine, and is esteemed an antidote to those which are poisonous.

ACO

poisonous. This is by some writers titled Anthora, and by others Antithora, as the poisonous kinds have been called Thora. Whenever therefore any of the species of this genus is ordered in medicine, this is the sort intended.

Most, if not all the other sorts are esteemed poisonous; but those with blue flowers are supposed to be of a much stronger quality, than the yellow or white flowered kinds. It is confidently affirmed, that the huntsmen on the Alps, who hunt the wolves and other wild animals, dip their arrows into the juice of these plants, which renders the wounds made by them deadly.

The sixth sort is the first which flowers; this grows near four feet high, and the spikes of flowers are upward of two feet long, so that when it is in flower, it makes a pretty appearance; and being very hardy, growing in any soil or situation, and multiplying greatly by the root, has induced many persons to allow it a place in their gardens, for the sake of its flowers, who being ignorant of its dangerous qualities, have permitted it to spread and propagate greatly. It flowers in May and June. The seeds are ripe in September; but as this sort multiplies so greatly by the root, it is rarely propagated the other way.

The first and second sorts are the next which flower; these come about the middle of June, and if the season is not warm, will continue in flower till August. The first grows upwards of three feet high, and the second above four, the spikes of flowers too in this being much longer than the former.

The third sort flowers a little later than either of those, but seldom grows more than two feet high, and the spikes of flowers are much shorter than either of the two last.

The wholesome Wolfsbane flowers in the middle of August, and often continues in beauty till the middle of September; the flowers are not so large as those of some other sorts, but being of a sulphur colour, make a pretty appearance in the borders of the flower-garden.

This sort will not thrive so well under the shade of trees as many of the other sorts, and therefore must have an open exposure.

The ninth and tenth sorts flower the beginning of July. The ninth usually grows about four feet high, but the tenth I have seen upwards of six. This sort is at present very rare in Europe. It was found by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris, where it was first cultivated in Europe, and from that garden, others have been furnished with the seeds.

The eighth sort flowers in July. This grows about four feet high, having a long spike of yellow flowers of a middling size, wherefore they may be allowed a place among shrubs, or in such parts of the garden as are not frequented by children.

The fifth, sixth, and seventh sorts flower in August, when they make a pretty appearance; and were it not for their noxious quality, would deserve a place in every garden. There are two or three varieties of the fifth sort, one with white, another with Rose coloured, and a third with variegated flowers; but these are only varieties which often change. The Napellus minor is also apt to change in the colour of its flower; of this sort I have had some plants with variegated flowers, but they changed in two years and became plain, nor did their seeds produce any plants with variegated flowers. The seventh sort will grow to the height of five feet in good ground; the flowers are very large, but not many upon each spike. These are of a deep blue colour.

All the sorts of Monkshood may be propagated by seeds, which should be sown in the autumn, in a shady situation: the plants often come up the first year, if the seeds are sown in autumn, otherwise it is the second spring before they appear; therefore the ground should be kept clean from weeds all the following summer, and when the plants come up, they should be watered in dry weather until they are fit to transplant; when they are to be carefully taken up, and planted in shady borders, at the distance of four

ACT

inches each way, observing to water them until they have taken good root in the ground; after which time they will require no other care but to keep them clean from weeds, till the following autumn, when they may be transplanted to the places where they are to remain.

The common Monkshood will grow under the shade of trees, in wildernesses or woods, and will increase fast enough by means of its creeping roots; but tho' most of the other sorts delight in shade, yet few of them will thrive under trees, for which reason they should be planted in shady borders which are not overhung by trees, where they will continue much longer in flower, and thrive better than in an open exposure.

ACONITUM HYEMALE. See HELLEBORUS.

ACORUS, the Sweet Rush.

The CHARACTERS are,

It hath a simple cylindrical stalk, which is closely covered with small flowers, so as to form a sort of katkin (or iulus). These flowers have no empalement, but are composed of six concave obtuse petals. In the center of the flower is situated a swelling germen, attended by six stamina, which are extended beyond the petals, and are crowned with thick double summits; the germen afterward turns to a short triangular capsule, having three cells, in which are lodged oval oblong seeds.

Dr. Linnæus ranges this genus in his sixth class of plants, entitled Hexandria monogynia, the flowers having six stamina and one style.

We have but one SPECIES of this plant,

ACORUS (Calamus) Roy. Leyd. 6. *The sweet smelling Flag or Calamus.* Acorus verus, five calamus aromaticus. C. B. P. 34.

This plant grows naturally in standing waters which are shallow, and is found wild in some parts of England; particularly in Norfolk, and also near Uxbridge in Middlesex, and in several parts of the north. In Holland this plant abounds in most of their ditches and standing waters. The leaves of this plant, when broken, send forth a strong aromatic scent; the roots are much stronger, and have been long used in medicine. This may be transplanted into a garden, where if the ground is moist, it will grow very well; but never produces its spike, unless it grows in the water. It loves an open situation, and will not thrive well under the shade of trees. The spikes of flowers (which are by many writers termed (Juli) appear toward the latter end of June, and continue till August. When this plant is fixed in a proper situation, it will multiply by its creeping roots fast enough.

ACRIVIOIA. See TROPÆOLUM.

ACTÆA, Herb Christopher.

The CHARACTERS are,

The empalement of the flower is composed of four concave obtuse leaves, which fall off; the flower hath four petals which are much larger than the empalement. In the center is placed the oval germen, crowned with an oblique depressed stigma, attended by numerous slender stamina, crowned with erect double roundish summits. After the flower is past, the germen becomes an oval or globular berry, having one cell, in which are lodged four seeds, which are roundish on their outside, but angular where they are joined.

Dr. Linnæus ranges this genus under his thirteenth class of plants, entitled Polyandria monogynia, the flowers having many stamina and one germen.

The SPECIES are,

1. ACTÆA (Spicata) racemo ovato fructibusque baccatis. Lin. Sp. Plant. 504. *Common Herb Christopher, or Bane Berries.* Christophoriana vulgaris nostras racemosa & ramosa. Mor. Hist. p. 2, 8.
2. ACTÆA (Alba) racemo ovato baccis niveis, radice tuberosa. *American Herb Christopher, with white berries.* Christophoriana Americana baccis niveis. Mor. Hist. p. 28.
3. ACTÆA (Racemosa) racemis longissimis fructibus unicapularibus. Lin. Sp. Pl. 504. *American black or wild Snakeroot.* Christophoriana Americana procerior & longius spicata. Hort. Elth. 79.

The first sort grows naturally in several places in the northern counties of England: I found it in pretty great

A D A

great plenty in a wood near Kirby Lonsdale, as also near Ingleborough Hill in Yorkshire. It grows two feet and a half high, the foot-stalks of the leaves arise from the root; these divide into three smaller foot-stalks, each of which divide again into three, and these have each three lobes, so that each leaf is composed of twenty-seven lobes (or small leaves). The flower-stem which arises from the root, is garnished with leaves of the same form, but are smaller. On the top of the stalk appears the flowers, which grow in ramose spikes, and are of a pure white; these come out in May, and are succeeded by black shining berries about the size of Pease, which ripen in the autumn. This is propagated by seeds, which should be sown soon after they are ripe; for if they are kept out of the ground till spring, the plants will not come up till the year after, so that a whole year will be lost. They should be sown on a shady border, and kept clean from weeds. As the seeds seldom come up all at the same time, the border in which they are sown should not be disturbed till the following autumn, to see what plants may appear; when the plants should be transplanted into a shady border, where they may remain to flower. This plant hath a perennial root, which lasts many years, but the stalk is annual, and perishes in autumn, soon after which is the best time to transplant them.

The second sort grows naturally in North America, from whence I have received the seeds; the leaves of this are somewhat like those of the first sort, but are not so deeply indented on their edges. The flowers grow in a more compact spike, and the berries are very white and transparent when ripe; the roots of this is composed of thick tubers, or knobs. This is an abiding plant, and delights in a light moist soil, and a shady situation; it may be propagated in the same manner as the former.

The third sort is a native of North America, where it is called Black Snakeroot, to distinguish it from the common Snakeroot. This plant hath large compound leaves, which rise immediately from the root, and are branched after the same manner as the first sort, which grow more than two feet high. The flower-stems frequently rise to the height of four or five feet, being terminated by a long spike of white flowers, which is reflexed at the top. This flowers in June, or beginning of July, but does not perfect seeds in England. During the time of its flowering, the plant makes a good appearance in a garden, and therefore deserves a place in the shady borders, or among shrubs; where, if it be not over-hung by them, it thrives very well, and being hardy, will require no other care than the shrubs themselves. It is generally propagated by seeds, which are annually sent from North America; it loves a moist light soil, and a shady situation.

The root of this plant is greatly used by apothecaries and physicians in America, in many disorders, and is supposed to be an antidote against poison, or the biting of the rattle-snake.

ADANSONIA, Ethiopian four Gourd, or Monkies Bread.

This plant is so named from one Mr. Adanson, a French surgeon, who resided some years at Senegal, in Africa, and during that time made several discoveries in natural history, and brought home a curious collection of seeds and plants.

The **CHARACTERS** are,

It hath a cup-shaped empalement, divided into five segments at the brim; which turn backward, and the empalement falls off: the flower has five roundish petals, whose brims are reflexed; at the tail of these are situated many stamina joined in a tube, which spread horizontally above, and are crowned by kidney-shaped summits. The germen is oval, the styles are long, variously intorted, having many hairy stigma. It hath a large ovalligenous capsule of ten cells, filled with a farinaceous sour pulp, inclosing many kidney shaped seeds.

This genus of plants is ranged in the fifth section of Linnaeus's sixteenth class, intitled Monodelphia polyandria, the flowers having many styles which coalesce with the stamina in one house.

A D E

There is known but one **SPECIES** at present,

ADANSONIA. This is the Baobab. Alp. Egypt. c. 27. f. 28.

The young plants, and also most of the new branches, have single spear-shaped leaves towards their lower part, but at their extremities the leaves have some three, and others five lobes, of the same size and form as the lower, which are disposed like a hand; these are entire, ending in a point, and fall off in winter. The stems are large and woody, but of a soft texture, and have generally a large swelling near the root.

It is propagated by seeds, which must be procured from the country where it grows naturally (for it doth not produce any in Europe); these must be sown in pots, and plunged into a hot-bed, where, in about six weeks, the plants will come up, and in a short time after be fit to transplant; when they should be each planted into a separate pot, filled with light sandy earth, and plunged into a fresh hot-bed, observing to shade them until they have taken new root; after which time they should have free air admitted to them every day in warm weather, but must be sparingly watered; for as their stems are soft (especially when young) too much wet will cause them to rot. As the plants advance in their growth, they are to be shifted into larger pots, but must constantly be plunged into the bark-bed, being too tender to thrive in this country without this artificial heat, therefore they must constantly remain in the stove with other tender exotic plants: the plants when young make great progress in their growth, where they are properly treated; for in three years many of them have been more than six feet high, and have put out several lateral branches, their stems were also proportionable; but after four or five years growth, they are almost at a stand, their annual shoots rarely exceeding two or three inches.

The account which Monsieur Adanson gives of the trees he saw at Senegal and other parts of Africa, in regard to the size of them is amazing, several of which he measured round their stems from sixty-five to seventy feet in circumference, but their height was not extraordinary. The trunks of these trees were from eight to twelve feet high, dividing into many horizontal branches which touched the ground at their extremities; these were from forty-five to fifty-five feet long, and were so large in circumference, that each branch was equal to a monstrous tree in Europe; and where the water of a neighbouring river had washed away the earth, so as to leave the roots of one of these trees bare and open to sight, they measured one hundred and ten feet long, without including those parts of the roots which remained covered with earth or sand: for he describes the plains where the trees grow to be a barren moveable sand, so that from its being continually shifted by the winds, there are no tracts discoverable, whereby persons can be guided in travelling over them.

Prosper Alpinus in his history of Egyptian plants, describes this tree, to which he gives the title of Baobab, so that it also grows in that country; but he does not mention any of them to be near the size of those described by Monsieur Adanson.

There were some plants of this sort in several gardens, which were raised from seeds obtained from Grand Cairo in the year 1724, by the late Dr. William Sheppard, some of which were grown to the height of eighteen feet; but in the severe winter 1740, they were all lost, and since that time there has not been any of the seeds brought to England, till the return of Mr. Adanson to Paris in 1754, who sent some of the seeds over here, which have succeeded, and many of the plants are now upwards of eight feet high.

ADELIA, we have no English title for this genus of plants.

The **CHARACTERS** are,

It hath male and female flowers upon different roots: the male flowers have an empalement of one leaf cut into five concave segments, but no corolla; it hath many slender stamina the length of the empalement, crowned by roundish summits. The female flowers have a five leaved concave empalement which is permanent; they have no corolla, but

A D E

a roundish germen with three short divaricated styles, and torn stigma. The capsule hath three cells, each containing one roundish seed.

This genus of plants, is ranged by Dr. Linnæus, in the twelfth section of his twenty-second class, which includes those which have male flowers on distinct plants from the female, whose stamina join at their base.

The SPECIES are,

1. ADELIA (*Bernardia*) foliis oblongis tomentosis ferratis. Lin. Sp. Plant. 1473. *Adelia with oblong, woolly, sawed leaves.*
2. ADELIA (*Ricinella*) foliis obovatis integerrimis. Lin. Sp. Plant. 1473. *Adelia, with oval entire leaves.*
3. ADELIA (*Acidoton*) ramis flexuosis, spinis gemmaceis. Amœn. Acad. 5. 411. *Adelia with flexible branches and prickly gems.*

These plants grow naturally in the island of Jamaica, and are near a-kin to the Ricinus, or Croton, but the male flowers growing upon different plants from the female, has occasioned their being ranged in a different class. Dr. Houstoun constituted a genus of them by the title of *Bernardia*, in honour to Dr. Bernard de Jussieu, demonstrator of plants in the royal garden at Paris; but Dr. Linnæus has fixed the title of *Adelia* to them. The plants are propagated by seeds, when these can be procured from the countries where they grow, for they do not produce good seeds in England. The seeds must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a separate small pot, filled with light earth, and plunged into a hot-bed of tan, treating them in the same manner as is hereafter directed for *Croton*. In the autumn, the pots should be plunged into the tan-bed in the stove, where, if they are kept in a temperate heat in winter, and not over-watered during that season, the plants may be preserved, and the summer following will produce flowers; but as these have little beauty, the plants are seldom propagated except in botanic gardens.

ADENANTHERA. Prod. Leyd. 462. Bastard Flower-fence.

The CHARACTERS are,

The empalement of the flower is of one leaf, slightly cut into five at the top; the flower is of the bell-shaped kind, and is composed of five petals, which are reflexed and concave on their under side. In the center is situated an oblong germen, supporting a style crowned with a single stigma; this is attended by ten erect stamina of the same length, which are crowned with roundish summits; after the flower is past, the germen becomes a long compressed pod, containing many convex smooth seeds, placed at a distance from each other.

Dr. Linnæus ranges this genus of plants in the first section of his tenth class, entitled *Decandria monogynia*, the flowers having ten stamina and one germen; but he separates it from the *Poinciana*, because the petals of the flower are equal, and the empalement is of one leaf, whereas the *Poinciana* hath a five leaved empalement, and the petals are unequal.

ADENANTHERA foliis decompositis. Prod. Leyd. 462. Bastard Flower-fence with compounded leaves.

There is another species, or at least a variety of this kind, with scarlet seeds, which is, at present rare in this country. I received the seeds of it from India, from which many plants have been raised, but they are of very slow growth in England.

The sort here mentioned grows to a very large tree in its native country, but it is so tender as to require a stove to preserve it through the winter in England, so that there are no large plants in the English gardens at present; the young plants which are not more than two feet high, have large branching leaves, composed of many equal divisions, garnished with small oval leaves, which are placed alternately on the midrib, and are of a bright green colour. The stems of the plants are woody, the bark of a brown colour, and the leaves continue all the year; but I have not seen any flowers produced in England as yet, but by some dried samples which were brought from India, they

A D O

seem to be small, and of little beauty; the fine branching leaves of the plant, however, make a very handsome appearance in the stove. The seeds are of a shining black colour, and are somewhat larger than those of the great Lentil, and nearly of the same shape. This plant must be raised on a hot-bed, and afterwards placed in the bark-stove with other tender exotics.

ADHATODA. See JUSTICIA.

ADIANTHUM, i. e. Maidenhair.

The CHARACTERS are,

This genus is distinguished from the other capillary plants by the fructification, being confusedly joined in oval spots, and the points of the leaves reflexed.

The SPECIES are,

1. ADIANTHUM (*Capillus Veneris*) frondibus decompositis foliis alternis pinnis cuneiformibus lobatis pedicellatis. Lin. Sp. Plant. 1096. *The true Maidenhair.* Adiantum foliis Coriandri. C. B. P. 356.
2. ADIANTHUM (*Pedatum*) frondibus pedatâ foliolis pinnatis pinnis antice gibbis incisus fructificantibus. Lin. Sp. Plant. 1095. *American Maidenhair.* Adiantum Americanum. Corn. Canad. 7. tab. 6.
3. ADIANTHUM (*Trapeziforme*) frondibus supradecompositis foliolis alternis, pinnis rhombeis incisus utrinque fructificationibus. Lin. Sp. Plant. 1097. *The largest black American Maidenhair with branching stalks, and leaves shaped like the figure of a rhombus.*

There are many species of this genus, which are natives of the East and West-Indies, greatly differing in size and form from each other. I have upwards of thirty distinct species in my collection of dried plants, which to enumerate in this place, would be superfluous, as they have not been introduced into the English gardens. The three sorts here mentioned, are all that I have seen growing in England.

The first sort is the true Maidenhair, which is directed to be used in medicine; but as it does not grow naturally in England, so the *Trichomanes* is usually substituted for it, which grows in great plenty in several parts of England. The other is a native of the south of France, Italy, and the Levant, from whence I have received the plants. It usually grows out of the joints of walls, and the fissures of rocks, so that whoever is inclinable to keep this plant in their gardens, should plant it in pots filled with gravel and lime rubbish, in which it will thrive much better than in good earth; but the pots must be sheltered under a frame in winter, otherwise the plants are often killed by the frost.

The second sort is often preserved in gardens for the sake of variety; this may be preserved in pots, and treated in the same manner as the former; for altho' it will live through the winter in the open air in moderate seasons, yet in severe frost it is sometimes destroyed. This grows naturally in Canada in such quantities, that the French send it from thence in package for other goods, and the apothecaries at Paris use it for the Maidenhair, in all their compositions in which that is ordered.

The third sort grows naturally in very warm countries; I received it from Jamaica in a tub of earth among other plants. This sort will not thrive in England, unless it be preserved in a stove, where its shining black stalks and odd shaped leaves will afford an agreeable variety among other exotic plants.

ADNATA, ADNESCENCIA, are those offsets, or small bulbs, which are produced from the roots of bulbous plants, and are closely connected to the parent root; of this sort is the *Narcissus*, *Amaryllis*, *Pancratium*, &c.

ADONIDIS HORTI, i. e. the gardens of Adonis, are plants, flowers, &c. in pots or cases, set on the outside of windows, in balconies, &c.

ADONIS, or FLOS ADONIS, Bird's-eye, or Pheasant's-eye.

The CHARACTERS are,

The empalement of the flower is composed of five concave, obtuse, coloured leaves which fall off; the flower is composed in some species of five petals, and in others of twelve

or

A D O

or fourteen. In the center there are many germina collected in a head, which are attended by a great number of short stamina, crowned by oblong inflexed summits; after the flower is past, the germina become so many naked seeds, closely adhering to the pedicle, and forming an obtuse spike. This genus is by Dr. Linnæus ranged in the seventh section of his thirteenth class, entitled Polyandria Polyginia, the flowers having many stamina and many germina.

The SPECIES are,

1. ADONIS (*Annua*) floribus octopetalis fructibus subcylindricis. Hort. Upsal. 156. The common Adonis, or Flos Adonis, with small red flowers.
2. ADONIS (*Æstivalis*) floribus pentapetalis fructibus ovatis. Annual Adonis with pale yellow flowers. Adonis Sylvestris flore luteo foliis longioribus. C. B. P. 178.

3. ADONIS (*Vernalis*) flore dodecapetalo, fructu ovato. Lin. Sp. Plant. 771. Perennial Adonis with yellow flowers, by some titled fennel-leaved black Hellebore. Adonis Hellebori radice Bupthalmi flore. H. L.

There is a variety of the first sort, which hath been long cultivated in the gardens; the flowers of this are larger, and the leaves shorter, than those of the wild sort; but, from many repeated trials of sowing their seeds separately, they appear to be only accidental variations arising from culture, and therefore may be properly esteemed as such.

The second sort is undoubtedly a distinct species. I have cultivated both these sorts above thirty years, and have never observed the second to vary either in the shape of its leaves, colour, make of the flower, or growth of the plants, which are much taller than the first, the leaves thinner, sparingly set on the stalks, and of a lighter colour.

Both these sorts are annual, and if the seeds are sown in autumn, the plants will come up the following spring; but when the seeds are not sown till spring, they rarely come up the same year: so that when the seeds are permitted to fall on the ground, they generally succeed better than when sown by art. The first sort grows naturally in Kent, particularly by the side of the river Medway, between Rochester and Maidstone, where it is found in great plenty in the fields which are sown with wheat; but in the intermediate years when the fields are sown with spring corn, there is rarely a plant of it to be found, which shews the necessity of sowing the seeds in autumn, for those fields of spring corn, if suffered to remain undisturbed after the harvest, will abound with this plant the following year. For some years past, great quantities of the flowers of this plant have been brought to London, and sold in the streets by the name of Red Morocco. Both these annual sorts flower in the beginning of June, and the seeds ripen in August and September; this must be understood of those plants which arise from seeds sown in autumn, or such as have fallen to the ground; for when any plants come up from the seeds sown in the spring (which sometimes happen) they do not flower till July or August, and their seeds seldom ripen before October.

These plants will thrive best in a light soil, but may be sown in any situation, so that by sowing some in a warm situation, and others in the shade, they may be continued longer in flower. The seeds ought to be sown where the plants are to remain to flower, for they do not bear transplanting, especially if they are not removed while the plants are very young: therefore they should be sown in small patches in the borders of the flower garden, and when the plants come up, they should be thinned, leaving three or four in each patch, which will make a better appearance than where they grow single.

The third sort hath a perennial root, and an annual stalk. This grows naturally on the mountains of Bohemia, Prussia, and other parts of Germany, where the root is often used as the true Black Hellebore, though from the descriptions given by the antients of that plant, this by no means will agree with them: this has been long cultivated in gardens. It produces

Æ S C

its flowers the latter end of March, or the beginning of April, according to the forwardness of the season: the stalks rise about a foot and a half high, and when the roots are large, and have stood unremoved for some years, they will put out a great number of stalks from each: these are garnished with fine slender leaves, which are placed in clusters at intervals. At the top of each stalk, is produced one large yellow flower, composed of an unequal number of petals, the center of which is occupied by a great number of germen, surrounded by many stamina; after the flowers drop, the germen become naked seeds, closely adhering to the foot-stalk, forming an obtuse spike. These ripen in August, and should be sown soon after, otherwise they seldom succeed.

When the plants come up, they must be carefully kept clean from weeds, and, in very dry weather, if they are now and then refreshed with water, it will promote their growth. They should remain in the place where they are sown until the second year, for they make but slow progress while young. The best time to transplant them is in autumn, when they ought to be planted where they are to remain, for if often removed, they will not produce many flowers, nor those flowers be so strong as on the plants which are unremoved.

ADONIA. Lin. Gen. 450. Moschatellina. Tourn. Inst. Tuberous Moschatel, or Hollow Root. This is ranged in Linnæus's eighth class, entitled Octandria Tetragynia, the flower having eight stamina and four styles.

The CHARACTERS are,

The empalement of the flower is bifid and permanent, upon which rests the germen; the flower is of one leaf, which is cut into four acute segments. The germen is situated in the center, supporting four erect styles, these are attended by eight stamina, crowned by roundish summits; after the flower is past, the germen becomes a round berry, resting on the empalement, which hath four cells, each containing a single compressed seed.

There is but one SPECIES of this genus.

ADONIA. Hort. Cliff. 152. Bulbous Fumitory Hollow Root, or tuberous Moschatel. Radix cava minima viridi flore of Gerard.

This plant grows naturally in shady woods in divers parts of England: I have frequently gathered it on the top of Hampstead among the bushes, near the wood; it is a very low plant, seldom rising more than four or five inches high, the leaves resemble those of the bulbous Fumitory, the flower-stalk arises immediately from the root, upon the top of which is placed four or five small flowers of an herbaceous white colour; these appear the beginning of April, and the berries ripen in May, soon after which the leaves decay.

There is little beauty in this plant, but as some persons are fond of collecting the several kinds of plants in their gardens, which are not commonly found, it is mentioned here. The roots may be transplanted any time after the leaves are decayed, till winter; these are tuberous, and shaped somewhat like a tooth. They must be planted in the shade, under shrubs; for if they are exposed to the open sun, they will not thrive. The leaves and flowers smell like Musk, from whence it has been by some called Musk-Crowfoot.

ÆGILOPS, Wild Festuc, a sort of grass which grows naturally in many parts of Europe, so is rarely cultivated except in botanic gardens.

ÆGOPODIUM, Small Wild Angelica, or Goutwort; this plant grows naturally in several places near London, but the roots run so fast in a garden, as to render it a troublesome weed.

ÆSCHYNOMENE. Lin. Gen. Plant. 769. Bastard Sensitive plant.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, entitled Diadelphia decandria; the flowers of this class have ten stamina, nine of which are united, and the other is separate.

The CHARACTERS are,

The empalement of the flower consists of one leaf, cut into two equal segments, the upper being bifid, and the lower

lower trifid; the flower is of the butterfly kind, the standard being large and heart-shaped; the two wings are oval, and shorter than the standard; the keel is moon-shaped, and as long as the standard. In the bottom of the flower is situated an oblong hairy germen, supporting an arched style, attended by ten stamina, nine of which coalesce, and the other is separated from them; after the flower is past, the germen becomes a long, plain, jointed pod, which separates at the joints, in each of which is lodged one kidney-shaped seed.

The SPECIES are,

1. *ÆSCHYNOMENE (Aspera)* caule scabro leguminum articulis medio scabris. Lin. Sp. Plant. 713. *Bastard Sensitive plant with a rough stalk, and a jointed pod.* Mimosa non spinosa major Zelanica. Breyn. Cent. 51.
2. *ÆSCHYNOMENE (Americana)* caule herbaceo hispido, foliolis acuminatis, leguminum articulis semicordatis, bracteis ciliatis. Lin. Sp. Plant. 1061. *Bastard Sensitive plant with a stinging herbaceous stalk, pointed leaves, and the joints of the pods heart-shaped.* Hedyfarum caule hirsuto mimosæ foliis alatis, pinnis acutis minimis gramineis. Sloan. Cat. Jam.
3. *ÆSCHYNOMENE (Arborea)* caule lævi arboreo leguminum articulis semicordatis glabris. Prod. Leyd. 384. *Bastard Sensitive plant with a smooth tree-like stalk, and smooth jointed pods.* Selban caule simplici glabro, foliis pinnatis glabris. Monier.
4. *ÆSCHYNOMENE (Selban)* caule herbaceo lævi, foliolis obtusis, leguminibus cylindricis æqualibus. Lin. Sp. Plant. 1061. *Bastard Sensitive plant with a smooth stalk, obtuse leaves, and equal cylindrical pods.* Galega Egyptiaca filiquis articulatis. C. B. P. 352.
5. *ÆSCHYNOMENE (Pumila)* caule herbaceo lævi, foliolis acuminatis, leguminibus hinc serratis medio scabris. Lin. Sp. Plant. 1061. *Bastard Sensitive plant, with a smooth herbaceous stalk, pointed leaves, and serrated rough pods.* Hedyfarum annuum minus Zeylanicum mimosæ foliis. Inst. R. H. 402.
6. *ÆSCHYNOMENE (Grandiflora)* caule arboreo, floribus maximis, leguminibus filiformibus. Lin. Sp. Plant. 1060. *Bastard Sensitive plant with a tree-like stalk, large flowers, and slender pods.* Galegæ affinis malabarica arboreascens, filiquis majoribus umbellatis. Raii Hist. 1734.

The first sort rises to the height of four or five feet, having a single herbaceous stalk, which is in some parts rough. The leaves come out on every side toward the top, forming a sort of head; these are composed of a great number of small leaves (or pinnæ) which are smooth, and of a glaucous colour. The flowers come out from between the leaves, two or three together upon long foot-stalks; they are yellow, and shaped like those of Pease. After the flower is past, the germen becomes a flat jointed pod, about four inches long, which, when ripe, parts at the joints, and in each division is lodged a single kidney-shaped seed.

The second sort seldom rises more than two feet high, but sends out three or four lateral branches; these are clothed with narrow winged leaves, whose pinnæ are placed alternate on the midrib. The flowers come out from the leaves upon branching foot-stalks, five or six together; these are much less than those of the first sort, and of a paler yellow colour. After the flowers are past, the germen becomes a jointed pod, having three or four swelling divisions, in each of which is lodged a single kidney-shaped seed.

The third sort grows to the height of six or seven feet, with a single stem; the leaves are smooth, and come out towards the top of the stalk, as in the first sort they are composed of many pinnæ, placed alternate on the midrib. The flowers come out from the wings of the leaves, two or three together, being of a copper colour, and as large as those of the first sort. After the flowers are past, the germen becomes a smooth jointed pod, each division being half heart-shaped, and inclosing a single kidney-shaped seed.

The fourth sort grows naturally in Egypt, and also on the coast of Guinea, from whence I received the seeds. This hath woody stems and branches, which

are garnished with smooth leaves, composed of many blunt pinnæ, set by opposite pairs; the flowers, which are small, and of a deep yellow colour, come out from the wings of the leaves in long spikes, which hang downward. After the flower is past, the germen becomes a taper-pointed smooth pod, not jointed.

The fifth sort rises about three feet high, with a single herbaceous stalk, seldom putting out any side branches. The flowers come out from the wings of the leaves, sometimes single, and other times two or three upon each foot-stalk; these are small, and of a pale yellow colour. After the flower is past, the germen becomes a long falcated pod, divided into eleven, or thirteen partitions, each containing a single kidney-shaped seed.

The sixth sort rises six or eight feet high, with a woody stem, sending out branches towards the top, garnished with obtuse leaves; the flowers are large, yellow, and succeeded by large pods, including kidney-shaped seeds.

The first, third, and fourth sorts, will live through the winter in England, if placed in a warm stove; but as their stalks are succulent, they must be kept dry in winter, otherwise they are very subject to rot. They should be plunged into the tan-bed, for when put into a dry stove, the fibres of their roots soon grow dry, and their leaves hang and fade, which shews their want of moisture; but when they have water given them, it causes the tender fibres of their roots to perish, and the plants soon after decay.

The fifth sort is annual, therefore the seeds should be sown early in March on a hot-bed, and the plants should be brought forward in the spring, and afterwards placed in an airy glass-case, or a stove in summer, for if they are exposed to the open air, the seeds rarely ripen in England.

The sixth sort grows to a large shrub in hot countries, but is with difficulty preserved through the winter in this country. The plants are propagated by seeds, which must be sown on a hot-bed in the spring, and the plants, when fit to remove, should be planted in pots, and brought forward on a hot-bed, then should be plunged into the bark-bed in the stove, where, if they are tenderly treated, they will live through the winter, and flower the summer following.

These are all propagated by seeds, which should be sown on a hot-bed early in the spring, and when the plants have strength enough to be removed, they should be put each into a separate small pot, filled with light earth, and plunged into a fresh hot-bed, to bring them forward; and as they advance in their growth, they should be shifted into large pots, but great care should be taken not to over-pot them, for if the pots are too large, the plants will not thrive.

The first, second, and fifth sorts are annual, therefore must be brought forward early in the year, otherwise they will not perfect their seeds; but the third, fourth, and sixth sorts may be preserved through the winter, and will flower early the following summer, and their seeds will ripen in the autumn. The other sorts usually flower in July, and their seeds ripen in October.

ÆSCULUS. Lin. Gen. 420. The Horse Chestnut.

The CHARACTERS are,

The empalement of the flower consists of one leaf, slightly cut into five segments. The flower is composed of five roundish petals, folded at their border, and waved; these are narrow at their base, and are inserted in the empalement. In the center is placed a roundish germen, having a single style, crowned with a pointed stigma; attended by seven stamina, which extend to the length of the petals, and are declining, crowned with upright summits. When the flower is past, the empalement becomes a thick, roundish, echinated capsule, opening into three cells, in one or two of which are lodged globular seeds.

This genus of plants, is, by Dr. Linnæus, ranged in his seventh class, entitled Heptandria Monogynia, the flower having seven stamina and one style.

The SPECIES are,

1. *ÆSCULUS (Hippocastanum)* floribus heptandriis. Hort. Upsal. 92. *The common Horse Chestnut.* Hippocastanum

num vulgare. Tourn. Inst. Castanea equini. Clus. Hist. 1. p. 7.

2. *ÆSCULUS (Pavia) floribus octandris.* Lin. Sp. 488. *Scarlet Horse Chestnut.* Pavia. Boerh. Ind. Alt. 2. p. 260. The Horse Chestnut was brought from the northern parts of Asia about the year 1550, and was sent to Vienna about the year 1588. It was called Castanea from the shape of its fruit, and the title of Equini was added to it from its being a good food for horses when ground.

This tree was in much greater esteem formerly than at present, for since it is become so very common, few persons regard it. What has occasioned its being so seldom planted, is the decay of the leaves early in summer; so that where they are growing in gardens, their leaves frequently begin to fall in July, and occasion a litter from that time, until all the leaves are fallen; but notwithstanding this inconvenience, the tree has great merit, for it affords a noble shade in summer; and during the time of its flowering, there is no tree has greater beauty, for the extremity of the branches are terminated by fine spikes of flowers, so that every part of the tree seems covered with them; which are finely spotted with a rose colour, and these being intermixed with the green leaves make a noble appearance.

The former method of planting these trees in avenues and strait lines, has also been in some measure the occasion of their present disrepute, because in such plantations great part of their beauty is lost; for when their branches are so far extended as to nearly meet, most of the flowers which are produced are hid from sight, and as the trees grow larger, their branches will interfere with each other, and produce few flowers; the leaves will also decay much sooner in close plantations, than on single trees: therefore the great beauty of them is, to stand singly at a distance from all other trees, upon lawns of grass in parks, where their fruit will be of great service to deer, who are very fond of them. In such situations, when the trees are grown to a good size, there is not a finer object than they will afford during their season of flowering, which is in May, and when the weather is moderate, they will continue in beauty near a month.

As this tree is quick in its growth, so in a few years they will arrive to a size large enough to afford a good shade in summer, as also to produce plenty of flowers. I have known trees which were raised from nuts, in twelve or fourteen years, large enough to shade two or three chairs under the spread of their branches, and have been covered with flowers in the season, so that few trees make greater progress than these. But as their wood is of little value, the trees should not be propagated in too great plenty: a few therefore of them placed at proper distances in parks for ornament is as many as should be preserved, the wood not being fit even for burning, nor any other use that I know of. These trees are propagated by sowing the nuts; the best time for doing this is early in the spring; but the nuts should be preserved in sand during the winter, otherwise they are apt to grow mouldy and rot. They may indeed be planted in autumn, but then they will be in danger of rotting if the winter should prove very wet, as also of being removed or eaten by vermin.

When the nuts succeed, and have a proper soil, the plants will shoot near a foot the first summer; so that where they grow pretty close together, it will be proper to transplant them the following autumn, when they ought to be planted in rows at three feet distance, and one foot asunder in the rows: in this nursery they may remain two years, by which time they will be fit to plant where they are designed to be continued; for the younger these trees are planted out, the larger they will grow. But there are many who will object to their being planted out young in parks, because they will require a fence to secure them against the cattle; which will also be necessary, whatever size they are when planted; and if large, they must be well staked to prevent their being displaced by strong winds: which is another expence, and when we con-

sider how much faster a young tree will grow, than those which are removed at a greater age, there can be no excuse for planting large trees.

This tree is not very nice in its culture, for it requires little care in the management, and will thrive in most soils and situations, but in a sandy loam they make the greatest progress; and if the soil be inclining to moisture, the leaves will continue in verdure much longer, than in very dry ground.

When these trees are transplanted, their roots should be preserved as entire as possible, for they do not succeed well, when torn or cut; nor should any of the branches be shortened, for there is scarce any tree, which will not bear amputation better than this; so that when any branches are by accident broken, they should be cut off close to the stem, that the wound may heal over.

There is something very singular in the growth of these trees, which is the whole shoot being performed in less than three weeks, after the buds are opened; in which time I have measured shoots a foot and a half long, with their leaves fully expanded: and no sooner are the flowers fallen, than the buds for the succeeding year are formed, which continue swelling till autumn; at which time the folding covers are spread over with a thick tenacious juice, which serves as a pigment to defend the tender buds from the frost and rain in winter; but upon the first return of warmth in the spring, this melts and runs off, whereby the bud is at full liberty to extend. And what is remarkable in this pigment, it is never so far hardened as to injure the tender buds, which are always formed at the extremity of the former year's shoot; a plain direction not to shorten them, for by so doing, the future shoots are entirely cut off.

In Turkey the nuts of this tree are ground, and mixed with the provender for their horses, especially those which are troubled with coughs, or are broken winded; in both which disorders, they are accounted very good. Deer are very fond of the fruit, and at the time of their ripening will keep much about the trees, but especially in strong winds, when the nuts are blown down, which they carefully watch, and greedily devour as they fall.

There are some old trees now standing, which were planted single, at a great distance from any other; these are grown to a very large size, and their heads form a natural parabola, and when their flowers are in full beauty, there is not any tree yet known in Europe, which makes so fine an appearance. I have measured some of these trees, whose branches have extended more than thirty feet in diameter, and their heads have been so close, as to afford a perfect shade in the hottest seasons. These were planted in 1679, as appears by some writings which are in the possession of the persons, who have now the property of the land where they grow: so that although they are of quick growth, yet they are not of short duration.

The Scarlet Horse Chestnut grows naturally in North America, where it rises to the height of twenty feet, but does not spread its branches to any great extent, the flowers are wholly red, which are much smaller than those of the common sort, they are tubulous, but want brims to expand, so make but an indifferent appearance, when compared to the other: however for variety this should have a place in gardens.

It may be propagated by the nuts, if they are procured from the country where the trees naturally grow; for the seasons are seldom favourable enough to ripen them in England. The nuts should be sown in pots early in the spring, and the pots plunged into a moderate hot-bed to forward their growth; toward the end of May, the pot should be plunged into the ground in a south-east border, and in dry weather the plants should be duly watered, whereby they will acquire strength by the autumn; when it will be very proper to screen the plants from early frosts which often pinch the top buds, and occasion their decay in the winter, for while the plants are young they are impatient of frosts, but when they have obtained strength.

strength it seldom hurts them: the spring following the plants should be carefully separated and planted a foot distance from each other in a sheltered situation; and the following winter, if it proves cold, it will be proper to cover the plants with some light covering to protect them; after the second winter they will require no farther sheltering.

The common method now practised by the nurserymen, who propagate these trees for sale, is by grafting or budding them upon stocks of the Horse Chestnut, but as the stocks greatly out-grow the buds or grafts, they have a bad appearance; nor do the trees last long.

ÆTHER [of *αἰθήρ*, Gr. to burn or flame; some of the ancients having supposed it to be of the nature of fire.] It is usually understood to be a thin subtle matter or medium, much finer and rarer than air itself, which commences from the limits of the atmosphere, and possesses the whole heavenly space. See **ATMOSPHERE** and **AIR**.

AGAVE, Lin. Gen. 390. American Aloe.

The **CHARACTERS** are,

The flower has no empalement, is funnel-shaped, and of one leaf, which is cut at the brim into six equal segments; the oblong germen is situated below the flower, upon which rests the slender style, which is extended a considerable length beyond the petals, and is crowned by a three cornered stigma. This is attended by six erect stamina, of the same length, crowned by narrow summits; after the flower is past, the germen becomes an oblong three cornered seed vessel, having three cells, which are filled with flat seeds.

Dr. Linnæus has separated the plants of this genus from the Aloe, to which they had been joined by former botanists, because the stamina and style in these flowers are extended much longer than the corolla, and the corolla rest upon the germen, which in the Aloe are not so. We may also mention another difference in the growth of the plants, by which they may be distinguished before they flower; which is, all the plants of this genus have their center leaves closely folding over each other, and embracing the flower stem which is formed in the center; so that these never flower until all the leaves are expanded, to give the stem its liberty to advance, and when the flower is past, the plants die. Whereas the flower-stem of the Aloe, is produced on one side of the heart or center of the plant, so they flower annually, and the leaves are always more expanded, than those of this genus.

The **SPECIES** are,

1. **AGAVE** (*Americana*) foliis dentato-spinosis scapo ramoso. Gen. Nov. 1102. *The Great American Aloe, with a branching stalk.* Aloe Americano muricata. J. B.
2. **AGAVE** (*Virginia*) foliis dentato-spinosis scapo simplicissimo. Lin. Sp. Plant. 323. *American Aloe with a simple stalk.*
3. **AGAVE** (*Fetida*) foliis integerrimis. Gen. Nov. Sp. Pl. 323. *American Aloe with stiff whole leaves.* Aloe Americana viridi rigidissimo & foetido folio piet dicta indigenis. Hort. Amst. 2. p. 35.
4. **AGAVE** (*Tuberosa*) radice tuberosâ foliis longissimis marginibus spinosis. *American Aloe, with a tuberos root, and very long leaves, with spines on their edges.* Aloe Americana radice tuberosâ minor. Pluk. Alm. 19.
5. **AGAVE** (*Vivipara*) foliis reflexis, marginibus dentatis. *American Aloe with reflexed leaves, whose edges are indented.* This is by some called the Childing Aloe, from its producing young plants after the flowers. Aloe Americana sobolifera. Herm. H. Ludg. 16.
6. **AGAVE** (*Karatto*) foliis erectis lætè virentibus, marginibus fuscis minimè serratis. *American Aloe with long deep green leaves, edged with brown, and very slightly sawed.* This is called in America Karattò.
7. **AGAVE** (*Vera Cruz*) foliis oblongis marginibus spinosis nigricantibus. *American Aloe with oblong leaves, whose edges are closely beset with black spines, commonly called Broad-leaved Aloe from Vera Cruz.* Aloe Americana ex Verâ Cruce foliis latioribus & glaucis. H. L.
8. **AGAVE** (*Rigida*) foliis lineari-lanceolatis integerrimis rigidis aculeo terminatis. *Narrow-leaved Aloe from*

Vera Cruz. Aloe Americana ex Verâ Cruce foliis angustioribus minùs glaucis. Hort. Beam.

The first sort here mentioned, has been long preserved in the English gardens, where of late years there have been several of the plants in flower. The stems of this when the plants are vigorous, generally rise upward of twenty feet high, and branch out on every side, so as to form a kind of pyramid, the slender shoots being garnished with greenish yellow flowers, which stand erect, and come out in thick clusters at every joint. These have six long stamina, crowned with yellow summits, placed round the style, which is also extended to the same length as the stamina. After the flowers fall away, the germen, which is situated beneath the flower, becomes an oblong triangular vessel, divided into three cells, filled with compressed seeds; but these do not come to maturity in England.

When these plants flower, they make a fine appearance, and continue a long time in beauty, if they are protected from the cold in autumn, as there will be a succession of new flowers produced, for near three months, in favourable seasons. It has been generally believed, that this plant doth not flower until it is a hundred years old; but this is a great mistake, for the time of its flowering depends on the growth of the plants; so that in hot countries where they grow fast, and expand many leaves every season, they will flower in a few years, but in colder climates, where their growth is slow, it will be much longer before they shoot up their stem. There is a variety of this sort with striped leaves, which is now pretty common in the English gardens.

The plants of the second sort are so like those of the first, as not to be distinguished from them, but by good judges. The principal difference is, the leaves of this are narrower toward their extremity, and of a paler colour: the stems of this sort do not rise so high as the first, nor do they branch in the same manner, but the flowers are collected into a close head at the top, they are however of the same shape and colour. There has been three or four plants of this sort, which have lately flowered in England, one of which was in the Chelsea garden a few years past. This sort seldom puts out so many offsets as the common Aloe.

The seventh sort greatly resembles these, so that many persons have supposed it to be the same; but the leaves of this are much thinner, the indentures on their edges abundantly closer, and not so deep, as in either of the former; the spines too are blacker. How this differs from the others in flower I know not, having seen none of their flowers produced in England. These three sorts are hardy. I have known plants of the first sort live in the open air for some years in mild seasons, but in severe winters they are always killed, if not sheltered. They are propagated by offsets, which the first sort sends out in plenty, but the third seldom puts out any; so these may be increased by taking off some of the larger roots, at the time when the plants are shifted, planting them in pots filled with light sandy earth, which will shoot out and become good plants, as I have experienced. The second sort generally puts out suckers enough for propagation, though not in so great plenty as the first. All these should be planted in pots filled with light sandy earth, and housed in winter with oranges, myrtles, &c. and during that season, should have but little wet. In the summer they must be placed abroad in the open air, where they may remain till toward the end of October, when they should be housed again. The seventh sort being a little tenderer than the other two, should be put into the green-house before them, and may stay there a little longer in the spring. The third sort hath long narrow stiff leaves, of a pale green colour, not indented on their edges, but frequently a little waved: the side leaves spread open, but those in the center fold closely over each other, and strictly surround the bud. The plants of this sort rarely grow more than three feet high, but the flower-stem rises near twenty, and branches out much like that

A G A

that of the first, but more horizontally; the flowers are of the same shape, but smaller, and of a greener colour. After the flowers are past, instead of seed-vessels, young plants succeed to every flower, so that all the branches are closely beset with them. There was a plant of this kind which flowered in the Chelsea garden 1755, the stem of which begun to shoot the beginning of October, and by the end of that month was upwards of ten feet high, by the end of November it was near twenty, and the lower lateral branches were upward of four feet long, the others decreasing gradually, so as to form a regular pyramid. In December the stalks were closely garnished with flowers, and in the spring, when the flowers dropped off, they were succeeded by young plants, which as they fell off and dropped into the pots which stood near, put out roots and become good plants. This sort never produces offsets from the root, so that it cannot be increased but when it flowers, at which time there will be plenty enough. The old plant presently after dies.

The fourth sort hath leaves somewhat like the third in shape and colour, but they are indented on their edges, and each indenture terminates in a spine; the root of this sort is thick, and swells just above the surface of the ground, in other respects it agrees with the former. This sort hath not flowered in England, therefore I cannot tell how it differs in its flowers from the other. I have raised this from seeds which were sent me from America, but the plants never put out suckers from the roots, so that it can only be propagated by seeds. Dr. Linnæus supposes it to be the same with the third species, but whoever sees the plants will not doubt of their being different.

The fifth sort never grows to a large size; the leaves of it are seldom more than a foot and a half long, and about two inches and a half broad at their base; these end in a slender spine, being slightly indented on their edges; they are also reflexed backward toward their extremity, and are of a dark green colour. The flower-stem rises about twelve feet high, and branches out toward the top in the same manner as the third sort; the flowers are nearly of the same size and colour as those of the third, and after they fall off, are succeeded by young plants in the same manner. A plant of this kind flowered in the garden at Chelsea, in December 1754. This never produces any suckers from the root, so cannot be increased until it flowers.

The leaves of the sixth sort are from two feet and a half to three feet long, and about three inches broad, being of a dark green colour, ending in a black spine; the borders of the leaves are of a brownish red colour, and slightly serrated. These stand more erect than in the other species; but as this sort hath not flowered in England, so I cannot say how it differs from the other. The plants of it were sent me from St. Christopher's, by the title of Koratto, which I suppose is given indifferently to other species of this genus; for I have frequently heard the inhabitants of America call the common great Aloe by the same name.

The eighth sort hath long, narrow, stiff leaves, which are entire, and are terminated by a stiff black spine. These leaves are seldom more than two feet long, and little more than an inch broad, being of a glaucous colour. The side leaves stand almost horizontally, but the center leaves are folded over each other, and inclose the flower-bud. This sort never puts out suckers from the root, nor have I seen any plants of this kind in flower, although there are many of them in the English gardens, some of which are of a considerable age.

The third, fourth, fifth, sixth, and eighth sorts, are much tenderer than the others, so cannot be preserved through the winter in England, unless they are placed in a warm stove; nor will they thrive if set abroad in summer, therefore they should constantly remain in the stove, observing to let them enjoy a great share of free air in warm weather. They require a light sandy earth, and should have little wet in winter; but in warm weather, may be gently watered twice a week,

A G E

which is as often as is necessary; for if they have much water given them, it rots their roots, and then their leaves will decay and insects infest them. They should be shifted every summer into fresh earth, but must not be put into large pots, for unless their roots are confined, the plants will not thrive.

AGERATUM. Lin. Gen. Plant. 842. Bastard Hemp Agrimony.

The CHARACTERS are,

The flowers are included in one common oblong empalement, which is composed of many scales. These are uniform, tubulous, and hermaphrodite, and little longer than the empalement, each being cut at their margin into five segments, which spread open. These have five slender stamina, crowned with cylindrical summits: in the center of the flower is situated an oblong germen, supporting a slender style, crowned by two fine stigmas. The germen afterward becomes an oblong angular seed, crowned with its proper little cup, cut into five narrow segments, which spread open. The receptacle of the seed is small, naked, and convex.

This genus of plants is by Dr. Linnæus ranged in his seventeenth class, entitled Syngenesia polygamia æqualis, the flowers having their stamina joined together in a cylinder, and there being male, female, and hermaphrodite florets included in the same common empalement.

The SPECIES are,

1. **AGERATUM** (*Coryzoides*) foliis ovatis caule piloso. Lin. Sp. Plant. 839. Bastard Hemp Agrimony, with oval leaves and a hairy stalk. *Eupatorium humile* Africanum senecionis facie folio lamii. Herm. Pars 161.
2. **AGERATUM.** (*Houstonianum*) foliis oppositis petiolatis crenatis, caule hirsuto: Bastard Hemp Agrimony, with leaves having long foot-stalks placed opposite, whose edges are bluntly indented, and a hairy stalk. *Eupatorium herbaceum melissæ folio villosum flore cœruleo.* Houst. MSS.
3. **AGERATUM** (*Altissimum*) foliis ovato cordatis rugosis floralibus alternis, caule glabro. Lin. Sp. Plant. 839. Bastard Hemp Agrimony, with rough, oval, heart-shaped leaves, flower branches growing alternate, and a smooth stalk. *Eupatorium urticæ foliis Canadense flore albo.* H. L.

The two first are annual plants. The seeds of these must be sown on a hot-bed in the spring, and when the plants are come up and are strong enough to remove, they should be transplanted into another moderate hot-bed, observing to water and shade them until they have taken root, after which time they must have a good share of air in warm weather. In June they should be inured to bear the open air, toward the middle of which month, they may be transplanted into the full ground, where they will begin to flower in July, and continue flowering till the frosts in autumn destroy them. The seeds ripen in September and October, and when any of them scatter upon the ground, and the same earth happens to be put on a hot-bed the following spring, the plants will come up in great plenty, as they frequently do in the open air; but these plants will be too late to produce good seeds, unless the summer proves warm. The first sort grows naturally in Africa, and also in the islands of America; for in tubs of earth which I received with plants from Jamaica, Barbadoes, and Antigua, I have had plenty of the plants arise, from seeds which were scattered on the ground. The second sort was found growing naturally at La Vera Cruz, by the late Dr. William Houstoun, who sent the seeds to Europe, which have so well succeeded in many gardens, as to become a weed in the hot-beds. There is a variety of this with white flowers, which arises from the same seeds.

The third sort grows naturally in North America, but has been many years an inhabitant of the English gardens. This hath a perennial root and an annual stalk; the stalks will grow five or six feet high, and toward their tops put out side branches: the leaves are shaped like a heart. At the ends of the shoots the flowers are produced in large tufts, which are of a pure white; and

E

these

these appearing in October, at a season when there is a scarcity of other flowers, renders it more valuable.

This sort is propagated by seeds, as also by parting of the roots; the latter method is commonly practised in England, because there are few autumns so favourable as to ripen the seeds: but the seeds are frequently brought from North America, where this plant is very common; for being light, they are easily wafted about to a great distance, where they come to maturity; so that where there are any plants growing, all the adjoining land is filled with the seeds of them.

The best time for planting and transplanting the roots of this plant, is in autumn, soon after their stalks decay, that they may have good root before the drying winds come on, otherwise they will not flower strong, or make a good increase. The roots should be allowed three feet room every way, for as they spread and increase very much, so when they are cramped for room, the plants starve, and in dry seasons their leaves will hang. They delight in a rich moist soil and open situation, where they will produce many stalks from each root, which will grow so large as to form a considerable brush. This plant will bear the severest cold in winter.

AGERATUM, or MAUDLIN. See ACHILLEA.

AGERATUM PURPUREUM. See ERINUS.

AGNUS CASTUS. See VITEX.

AGRIFOLIUM. See ILEX.

AGRIMONIA. Lin. Gen. Plant. 534. Agrimony.

The CHARACTERS are,

The empalement of the flower is of one leaf, which is cut into five acute segments, and rests on the germen. The flower has five petals, which are plain and indented at their extremity, but are narrow at their base, where they are inserted in the empalement. In the center arises a double style, resting on the germen, which is attended by twelve slender stamina, which are crowned with double compressed summits. After the flower is past, the germen becomes two roundish seeds fastened to the empalement.

This genus of plants is ranged by Dr. Linnæus in the second section of his eleventh class, entitled Decandria digynia, the flowers having twelve stamina and two styles.

The SPECIES are,

1. AGRIMONIA (*Eupatoria*) foliis caulinis pinnatis impari petiolato, fructibus hispidis. Hort. Cliff. *The common Agrimony.* Agrimonia officinarum. Tourn.
2. AGRIMONIA (*Minor*) foliis caulinis pinnatis, foliolis obtusis dentatis. *The white Agrimony.* Agrimonia minor flore albo. Hort. Cath.
3. AGRIMONIA (*Odorata*) altissima, foliis caulinis pinnatis foliolis oblongis acutis serratis. *The sweet-scented Agrimony.* Agrimonia odorata. Camer.
4. AGRIMONIA (*Repens*) foliis caulinis pinnatis, impari sessili, fructibus hispidis. Lin. Sp. 643. *Eastern Agrimony with pinnated leaves and a thick creeping root.* Agrimonia orientalis humilis radice crassissima repente fructu in spicam brevem & densam congesto. Tourn. Cor.

5. AGRIMONIA (*Agrimoides*) foliis caulinis ternatis fructibus glabris. Hort. Cliff. 179. *Three leaved Agrimony with smooth fruit.* Agrimoides Col. Echpr.

The first sort grows naturally in several parts of England, by the sides of hedges, and in woods. This is the sort which is commonly used in medicine, and is brought to the markets by those who gather herbs in the fields.

The second sort is the smallest of all the species; the leaves of this have not so many pinnæ as the common sort, and the pinnæ are rounder, and the indentures on their edges blunter. The spike of flowers is slender, and the flowers smaller, and of a dirty white colour. This sort grows naturally in Italy, from whence I received the seeds, and have constantly found that the seeds of this when sown never vary.

The third sort grows near four feet high; the leaves of this have more pinnæ than either of the former, which are longer and narrower, ending in acute points; the serratures of the leaves are sharper than any of the other, and when handled emit an agreeable odour. The leaves of this sort make an agreeable cooling tea,

which is a very good beverage for persons in a fever, in which disorder I have known it often prescribed by good physicians.

The fourth sort is of humble growth, seldom rising above two feet high; the pinnæ of its leaves are longer and narrower than either of the former, and the spikes of flowers very short and thick. The roots of this are very thick, and spread widely under ground, by which it multiplies faster than either of the other; the seeds are also much larger and rougher than those of the common sort. This was sent by Dr. Tournefort to the royal garden at Paris, and from thence the other botanic gardens have been supplied with them.

The fifth sort greatly resembles the other in the shape of its pinnæ (or smaller leaves) but there are but three upon each foot-stalk; the flower of this hath a double empalement, the outer one being fringed. There are but seven or eight stamina in each flower, and the seeds are smooth, for which reason Fabius Columna, and other writers on botany, have separated it from the Agrimony, making it a distinct genus.

All these sorts are hardy perennial plants, which will thrive in almost any soil or situation, and require no other care but to keep them clear from weeds. They may be propagated by parting of their roots, which should be done in autumn, when their leaves begin to decay, that the plants may be well established before the spring. They should not be planted nearer than two feet, that their roots may have room to spread. They may also be propagated by seeds, which should be sown in autumn, for if they are kept out of the ground till spring, they seldom come up the same season.

AGROSTEMMA. Lin. Gen. Plant. 516. Wild Lychnis or Campion.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, which is tubulous, thick, and cut into five narrow segments at the edge; the flower is composed of five petals, which are the length of the tube, but spread open at the top. In the center is situated an oval germen supporting five styles, which are slender, erect, and crowned with simple stigma. These are attended by ten stamina, five of which are inserted in the base of the petals, and the others stand alternately between: after the flower is past, the germen becomes an oval oblong capsule, having one cell opening into five divisions, which is filled with angular seeds.

This genus of plants is by Dr. Linnæus ranged in the fifth section of his tenth class, entitled Decandria pentagynia, the flowers of this division having ten stamina and five styles.

The SPECIES are,

1. AGROSTEMMA (*Githago*) hirsuta calycibus corollam æquantibus petalis integris nudis. Lin. Sp. Plant. 435. *Hairy wild Lychnis, whose empalement is equal with the corolla, and the petals entire and naked, commonly called Corn Campion.* Lychnis fegetum major. C. B. P.
2. AGROSTEMMA (*Celirosa*) glabra foliis lineari-lanceolatis petalis emarginatis coronatis. Hort. Upsal. 115. *Smooth wild Campion with narrow spear-shaped leaves, and the petals of the flowers indented at their brim.* Lychnis foliis glabris calyce duriore. Bocc. Sic. 27.
3. AGROSTEMMA (*Coronaria*) tomentosa foliis ovato-lanceolatis, petalis integris coronatis. Hort. Upsal. 115. *The single Rose Campion.* Lychnis coronaria Dioscoridis sativa. C. B. P. 203.
4. AGROSTEMMA (*Flos Jovis*) tomentosa petalis emarginatis. Lin. Sp. Plant. 436. *Umbelliferous Mountain Campion.* Lychnis umbellifera montana Helvetica. Zan. Hist. 128.

The first sort grows naturally in the corn fields in most parts of England, so is seldom admitted into gardens. The second sort grows naturally in Sicily, and being a plant of little beauty, is only preserved in botanic gardens for the sake of variety.

The single Rose Campion has been long an inhabitant of the English gardens, where, by its seed having scattered, it is become a kind of weed. There are three varieties of this plant, one with deep red, another with flesh-coloured, and a third with white flowers,

but

A I R

but these are of small esteem; for the double Rose Campion being a fine flower, has turned the others out of most fine gardens. The single sorts propagate fast enough by the seeds, where they are permitted to scatter, for the plants come up better from self-sown seeds, than when they are sown by hand, especially if they are not sown in autumn.

The sort with double flowers, which is a variety of the former, never produces any seeds, so is only propagated by parting of the roots; the best time for this is in autumn, after their flowers are past; in doing of this, every head which can be slipped off with roots should be parted. These should be planted in a border of fresh undunged earth, at the distance of six inches one from the other, observing to water them gently until they have taken root; after which they will require no more, for much wet is very injurious to them, as is also dung. In this border they may remain till spring, when they should be planted into the borders of the flower-garden, where they will be very ornamental during the time of their flowering, which is July and August.

The fifth sort grows naturally upon the Helvetian mountains; this is a low plant, with woolly leaves; the flower-stem rises near a foot high; the flowers grow in umbels on the top of the stalk, which are of a bright red colour. It flowers in July, and the seeds ripen in September. It must have a shady situation, and will thrive best in a moist soil.

A I R [*Aër*, Lat. *Aër*, of *ἄρ* *ἄρ* *πῦρ*, because it always flows; or as others, of *ἀήρ*, to breathe.] By air is meant all that fluid expanded mass of matter which surrounds our earth, in which we live and walk, and which we are continually receiving and casting out again by respiration.

The substance whereof air consists, may be reduced to two kinds, viz.

1. The matter of light or fire, which is continually flowing into it from the heavenly bodies.

2. Those numberless particles, which is in form either of vapours, or dry exhalations, are raised from the earth, water, minerals, vegetables, animals, &c. either by the solar, subterraneous, or culinary fire.

Elementary air, or air properly so called, is a certain subtle, homogeneous, elastic matter, the basis or fundamental ingredient of the atmospherical air, and that which gives it the denomination.

Air therefore may be considered in two respects; either as it is an universal assemblage, or chaos, of all kinds of bodies; or as it is a body endued with its own proper qualities.

1. That there is fire contained in all air is demonstrable, in that it is evident, that there is fire existing in all bodies, and to this fire it is that air seems to owe all its fluidity; and were the air totally divested of that fire, it is more than probable that it would coalesce into a solid body; for it is found by many experiments, that the air condenses and contracts itself so much the more, the less degree of warmth it has; and, on the contrary, expands itself the more, according as the heat is greater.

2. In respect of exhalations, air may be said to be a general collection of all kinds of bodies; for there are no bodies but what fire will render volatile, and disperse into air; even salts, sulphurs, and stones, nay and gold itself, though the heaviest and most fixed of all bodies, are convertible into vapours by a large burning-glass, and are carried on high.

Those floating particles, thus raised from terrestrial bodies, are moved and agitated by the fiery particles divers ways, and are diffused through the whole atmosphere.

Of the matters thus raised in the atmosphere, those which come from fluid bodies, are properly called vapours, and those from solid or dry ones, exhalations.

The cause of this volatility and ascent is the fire, without which all things would fall immediately down towards the center of the earth, and remain in eternal rest.

Thus, if the air be full of vapours, and the cold suc-

A I R

ceeds, these vapours before dispersed are congregated and condensed into clouds, and thus fall back again into the form of water, rain, snow, or hail.

From the time of the entrance of the spring till autumn, the evaporation is constant; but then it begins to fail, and in the winter ceases, to lay up fresh matter for the coming season.

And thus it is that frosty winters, by congealing the waters, and by covering the earth with a crust, and thus imprisoning the exhalations, make a fruitful summer.

And this seems to be the reason why in some countries, where the winter is severer than ordinary, the spring is more than ordinary fruitful; for in such places the exhalations being pent up a long time, are discharged in the greater quantity, when the sun makes them a passage; whereas, under a feebler cold, the flux would have been continual, and consequently no great stock reserved for the next occasion.

This vaporous matter then being at length received into the atmosphere, is returned again in the form of rain, a forerunner of a cheerful crop.

As the sun retires, the cold succeeds, and thus the diversity of the seasons of the year depends on a change in the face of the crust of the earth, the presence of the air, and the course of the sun.

And hence we conceive the nature of meteors, which are all either collections of such vapours and exhalations, or dispersions thereof.

The subtiler oils are always rising into the air. Now two clouds, partly formed of such oils, happening to meet and mix, by the attrition, the oil frequently takes fire, and hence proceed thunder, lightnings, and other phenomena, which may be farther promoted by the disposition of the clouds to favour the excitation.

And hence arise great and sudden alterations in the air, inasmuch that it shall be now intensely hot, and raise the spirits perhaps to eighty-eight degrees in a thermometer; and yet, after a clap of thunder with a shower, it shall fall again in a few minutes no less than twenty or thirty degrees.

It is therefore impossible to pronounce what the degree of heat will be in any given place at any time, even though we know ever so well the places and position of the sun and planets with respect to us, since it depends so much upon other variable things, no ways capable of being ascertained.

The lower the place, the closer, denser, and heavier is the air, till at length you arrive at a depth where the fire goes out; so that miners, who go deep, to remedy this inconvenience, are forced to have recourse to an artificial wind, raised by the fall of waters, to do the office of the other air.

Now, considering the air as such a chaos, or assemblage of all kinds of bodies, and a chaos so extremely liable to change, it must needs have a great influence on vegetable bodies.

3. Air considered in itself, or that properly called air. Besides the fire and exhalations contained in the circumambient atmosphere, there is a third matter, which is what we properly mean by air.

To define the nature of it would be extremely difficult, inasmuch as its intimate affections are unknown to us; all we know is,

1. That air is naturally an homogeneous similar body.

2. That it is fluid.

3. That it is heavy.

4. That it is elastic.

5. That it rarefies by fire, and contracts by cold.

6. That it is compressible by a weight laid thereon, and rises, and restores itself upon a removal of the same: all which circumstances should incline it to coalesce into a solid, if fire were wanting.

1. Air is divided into real and permanent, and apparent or transient.

Real air is not reducible by any compression or condensation, or the like, into any substance besides air.

Transient air is the contrary of the former, and by cold,

A I R

cold, &c. may be condensed into original water; the difference between permanent and transient air, amounts to the same as that between vapour and exhalation; the one, e. g. being dry, and the other moist. Hence, as Sir Isaac Newton says, it is, that as the particles of permanent air are grosser, and arise from denser bodies, than those of transient air or vapour, true air is more ponderous than vapour, and a moist atmosphere lighter than a dry one.

But this real air no where consists in its purity, but that air which concerns us, and the properties and effects of which are chiefly to be considered, is that which has been before treated on and described, which Mr. Boyle acknowledges to be the most heterogeneous body in the universe; and Dr. Boerhaave shews it to be an universal chaos and colluvies of all the kinds of created bodies in the universe, and in which may be found whatever fire can volatize.

2. That the air is fluid, appears from the easy passage it affords to bodies through it; as in the propagation of sounds, smells, and other effluvia; for these things shew it a body that gives way to any force impressed, and in yielding are easily moved among themselves, which are the properties of a fluid; so that scarce any body will call in question, whether air be a fluid, and thence being always in motion, and always moving other bodies, for no surface of any liquor that is contiguous to the air, can be at rest.

3. As to the gravity or heaviness of the air, that is likewise easily proved; for that the air is heavy, follows from its being a body, weight being an essential property of matter.

Sense and experiment sufficiently prove this: for, if a person lay his hand upon an open vessel placed on an air-pump, and the air be exhausted, he will sensibly feel the load of the incumbent atmosphere to increase, and press upon the upper part of his hand, as the air is exhausting.

In like manner, a hollow sphere of five or six inches diameter, divided into two segments exactly fitting each other, after the air is exhausted out of them, are pressed together with a force equal to a hundred pounds weight, and require the strength of two strong persons to pull them asunder; which, as soon as ever the air is let into them again, will fall asunder by the mere weight of the under hemisphere.

Mr. Boyle found that a lamb's bladder, containing about two thirds of a pint, and blown up, and well dried, lost about a grain and one eighth, when it was pricked, and the air let out.

Mr. Gravesande found, that the air in a glass ball of about two hundred and eighty-three inches capacity, weighed a hundred grains; and according to Burcher de Volder, a cubic foot of air is in weight one ounce, and twenty-seven grains.

Mr. Boyle has computed, that the weight of any quantity of air, near the surface of the earth, is to water as 1 to 1000; and Dr. Halley, as 1 to 800; and Mr. Hawksbee, as 1 to 885; and the gravity of the same quantity of air to the same quantity of mercury, as 1 to 10800.

Air therefore may be considered as an universal operculum, or cover, which by its weight keeps all terrestrial bodies down, and hinders them from flying off.

4. The air is elastic. Elasticity is a quality whereby a body yields to any external impressions by contracting itself into less compass; and upon removing or diminishing the impressive power, returns to its former space or figure. And by this quality, the air is distinguished from all other bodies in the atmosphere; neither fire nor exhalations appearing to be elastic, at least in any notable degree.

That there is such a quality in the air, is evident from innumerable experiments; and this property is inseparable from it. A bladder full blown being squeezed in the hand, the included air may be sensibly perceived to resist the touch; so that upon ceasing to compress it, the cavities or impressions, which were made in its surface, are immediately expanded again, and filled up.

A I R

Also thin glass bubbles, or bladders full of air, and exactly closed, and put into the receiver of an air-pump, the air being exhausted out of the receiver, the glass bubbles fly in pieces by the force of the air included in them.

From these experiments, and many others, it appears, that the air we breathe near the surface of the earth is compressed by its own weight into at least 1679 parts of the space it would possess in vacuo; and if the same air be condensed by art, the space it will occupy, when most dilated, will be as 505000 to 1, to that which it possesses when condensed; and Dr. Wallis suggests, that we are far from knowing the utmost it is capable of.

Nor does this power appear capable by any means to be destroyed or diminished; for Mr. Boyle made several experiments to discover how long air, brought to the greatest degree of expansion he could reduce it to in his air-pump, would retain its spring, and could never observe any sensible diminution; although the air was clogged some months with a weight that one would admire how it should support one moment.

It is, indeed, a wonderful property in air, that it should be capable of being contracted and extended infinitely; but, as hath been said, it does not appear, by all the experiments yet tried, that there are any limits of its compression or expansion; but still by the addition of a new weight, it will contract farther; and by taking the weight away, will expand farther.

5. Air rarefies by fire, and contracts by cold.

The colder the air is, the less space it takes up; and, on the contrary, the warmer the air is, it possesses the larger space; and so cooling and compression have the same effects upon air; and so cold and compression keep pace with one another.

The same holds of warming and diminishing of weight, or heat and expansion, which go hand in hand.

And to the same elastic power before-mentioned, and its being expanded by heat, it is owing, that air inclosed in glass vessels, at a time when it is much condensed, when it afterwards comes to expand by a farther degree of heat, frequently bursts the bottles.

6. Air is incompressible by a weight laid thereon, and rises and restores itself upon a removal of the same. This property has been sufficiently shewn by what has been said before, and especially under the head of elasticity; wherefore, having considered the properties of air, I shall take notice of some of its operations and effects as to the business of vegetation.

Air, by being heavy and fluid, invests the whole earth, and presses all the bodies thereon with a great force, equal to what they would sustain from the pressure of a column of 29 inches depth of mercury, or 32 feet of water; and constringes and binds them down with a force amounting, according to the computation of Mr. Paschal, to 2232 pounds weight upon every square foot, or upwards of 15 pounds upon every square inch. Hence it prevents, e. g. the arterial vessels of plants and animals from being too much distended by the impetus of the circulating juices, or by the elastic force of the air so plentifully lodged in the blood of one, and the sap of the other. For,

The air presses equally every way, as is confirmed in what we observe of soft bodies sustaining this pressure without any change of figure, and brittle bodies without their breaking.

Air is a principal cause of the vegetation of plants, an instance of which we have from Mr. Ray, in the Philosophical Transactions of Lettuce-seed, that was sown in the glass-receiver of the air-pump, which was exhausted and cleared from all air, which grew not at all in eight days time; whereas some of the same seed that was sown at the same time in the open air, was risen to the height of an inch and a half in that time; but the air being let into the empty receiver, the seed grew up to the height of two or three inches in the space of one week.

That a certain portion of air is necessary to preserve the growing quality of seeds is manifest, from many repeated

A I R

repeated experiments; by putting up seeds into glass bottles, and sealing the bottles hermetically, and in six months those seeds have lost their growing quality; whereas part of the same seeds which were kept in bags, grew at the age of two years; therefore it should caution persons not to exclude the air from their seeds, if they intend they should grow.

Another instance of the usefulness of the air in vegetation, is the Sedum, which will push out roots without earth and water, and live for several months: and some sorts of Aloes, if hung up in a room entirely secured from frosts, will remain fresh for some years, though they will sensibly lose in their weight.

Air is capable of penetrating the porous and spongy parts of plants, and being there contracted, and dilating itself again.

The air operates also within the bowels of the earth, and by its subtilty perspiring through the pores, assists in the rarefaction of the crudities of the earth, and in the dispelling all superfluous moisture, entering into the very pores and veins of the trees, plants, herbs, &c. carrying along with it those salts contained either in itself, or lodged in the earth; which salts or juices, are altered according to the several figures or dimensions of the different strainers or vessels of those several plants, which grow upon the same spot of earth, which is so impregnated with these salts: and thence those varieties in taste and smell proceed, notwithstanding they all receive their nourishment from the same stock that is lodged in the earth.

The air also affects the branches, leaves, and flowers of trees, plants, and herbs, entering and perspiring through them, and even through the bark and body of the tree; and by the same kind of subtilty it does, by its refreshing breezes, moderate the intenseness of the sun-beams, cooling, clearing, blowing, opening and extending all the offspring of nature.

The air fixes and insinuates its aerial substance into the liquid sap of vegetables: and as all the agitations in nature proceed from the contrariety of parts inhabiting together, in this, aerial and liquid substances being mixed, cause this agitation and motion in vegetables, or, more properly, set it all into a ferment (whether it be in the roots, or in the stem); and it rises by co-operation of the sun (which is the third agent in vegetation) up to the top of a tree, &c. as liquids rise by fire to the top of the containing vessel. This air, we find, produces a vibratory motion in several bodies; and particularly in plants, the air vessels thereof do the office of lungs: for the air contained in them, sometimes contracting, and sometimes expanding, according as the heat is increased or diminished, presses the vessels, and ease them again by turns; and thus promotes a circulation of their juices, which could scarce be otherwise effected.

Air, says the learned Dr. Hales, is a fine elastic fluid, with particles of very different natures floating in it, whereby it is admirably fitted by the great Author of nature to be the breath or life of vegetables as well as animals, without which they can no more live nor thrive than animals can.

As a proof of the great quantities of air in vegetables, he refers to the third chapter of his excellent treatise of Vegetable Statics, where he says, in the experiments on Vines, the great quantity of air was visible, which was continually ascending through the sap in the tubes; which manifestly shews what plenty of it is taken in by vegetables, and is perspired off with the sap through the leaves.

He adds several experiments, as to an Apple branch, Apricot branch, Birch, and other plants, to prove the same thing.

And Dr. Grew has observed, that the pores are so large in the trunks of some plants, as in the better sort of thick walking-canes, that they are visible to a good eye without a glass; but with a glass, the cane seems as if stuck at top full of holes with great pins, so large as very well to resemble the pores of the skin in the ends of the fingers and ball of the hand.

In the leaves of Pines, they are likewise through a

A I R

glass a very elegant shew, standing almost exactly in rank and file through the length of the leaves.

Whence it may be thought probable, that the air freely enters plants, not only with the principal fund of nourishment by the roots, but also through the surface of their trunks and leaves, especially at night, when they are changed from a perspiring, to a strongly imbibing state.

Dr. Hales likewise tells us, that in all those experiments that he tried to this purpose, he found that the air entered very slowly at the bark of young shoots and branches, but much more freely through old bark; and that in different kinds of trees it had different degrees of more or less free entrance.

And likewise, that there is some air both in an elastic and unelastic state, mixed with the earth (which may well enter the roots with the nourishment), he found by several experiments, which he gives in the before-mentioned treatise.

The excellent Mr. Boyle, in making many experiments on the air, among other discoveries found, that a good quantity of air was producible from vegetables, by putting Grapes, Plums, Gooseberries, Pease, and several other sorts of fruits and grains into exhausted and unexhausted receivers, where they continued for several days emitting great quantities of air.

This put the curious Dr. Hales upon farther researches to find out what proportion of air he could obtain out of the different vegetables, in which it was lodged and incorporated, which he performed by divers chymio-statical experiments, which he gives in many instances in his treatise of the analysis of the air, plainly shewing in what manner he performed them, and the events of them.

That from half a cubic inch, or 135 grains of heart of Oak, fresh cut from a growing tree, there were 108 cubic inches of air generated, which is a quantity equal to 216 times the bulk of the piece of Oak; that the weight of it was above 30 grains, one quarter part of the weight of 135 grains.

And he adds, that he took the like quantity of thin shavings from the same piece of Oak, and dried them at some distance from a gentle fire for 24 hours; in which time they evaporated 44 grains of moisture; which 44 grains deducted from 135 grains, there remains 91 grains for the solid part of the Oak: then 30 grains will be one third of the weight of the solid part of the Oak.

He gives another experiment of Indian Wheat, which grew in his own garden, that he took 388 grains of it when it was not come to its full maturity, and that there were generated from it 270 cubic inches of air; the weight of which air was 77 grains, viz. one fourth of the weight of the Wheat.

And again, that a cubic inch, or 318 grains of Pease generated 396 cubic inches of air, or 113 grains, i. e. something more than one third of the weight of the Pease.

And again, that from one ounce, or 437 grains of Mustard seed, 270 cubic inches of air were generated, or 77 grains, which is more than one sixth part of the ounce weight.

He likewise adds, that there is a great plenty of air incorporated into the substance of vegetables, which, by the action of fermentation, is roused into an elastic state, as is evident from these experiments following.

On the 2d day of March, he poured 42 cubic inches of ale from the tun, which had been there set to ferment 34 hours before into a bolt head; and from that time to the 9th of June, it generated 639 cubic inches of air, with a very unequal progression, more or less, as the weather was warm, cool, or cold; and sometimes, upon a change from warm to cool, it reformed air, in all 32 cubic inches.

From the 2d of March to the 16th of April, 12 cubic inches of Malaga Raisins, with 18 cubic inches of water, generated 411 cubic inches of air; and then again, it reformed 35 cubic inches in two or three cold days. From the 21st of April to the 16th of May, it generated 78 cubic inches; after which, the 9th of

June, it continued in a reſorbing ſtate, ſo as to reſorb 13 cubic inches: that there were at that ſeaſon many hot days, with much thunder and lightning, which deſtroys the elasticity of the air: there were generated in all 489 cubic inches, of which 48 were abſorbed. The liquor was at laſt vapid.

On the 10th of Auguſt, 26 cubic inches of Apples being maſhed, they generated 986 cubic inches of air in 13 days time, which is a quantity equal to 48 times their bulk; after which they reſorbed a quantity equal to their bulk, in three or four days, notwithſtanding the weather was then very hot; after which time they were ſtationary for many days, neither generating nor abſorbing.

From which before-mentioned experiments on Raiſins and ale, the ingenious author concludes, that wine and ale do not turn vapid in warm weather by imbibing the air, but by fermenting and generating too much; by which means they are deprived of their enlivening principle the air: for which reaſon, theſe liquors are beſt preſerved in cool cellars, whereby this active invigorating principle is kept within due bounds; which when they exceed, wines are upon the fret, and are in danger of being ſpoiled.

Upon theſe, and many other experiments, which the learned author has given in his aforeſaid treatiſe, he obſerves, that this air which ariſes in ſo great quantities from fermenting and diſſolving vegetables, is true permanent air; which is certain, by its continuing in the ſame expanded and elastic ſtate for many weeks and months; which expanded watery vapours will not do, but ſoon condeſce when cold.

Upon the whole, he concludes, that air abounds in vegetable ſubſtances, and bears a conſiderable part in them: and if all the parts of matter were only endowed with a ſtrongly attracting power, all nature would then immediately become one unactive cohering lump.

Wherefore it was abſolutely neceſſary, in order to the actuating this vaſt maſs of attracting matter, that there ſhould be every where mixed with it a due proportion of ſtrongly-repelling elastic particles, which might enliven the whole maſs by the inceſſant action between them and the attracting particles.

And ſince theſe elastic particles are continually in great abundance reduced by the power of the ſtrong attracters, from an elastic to a fixed ſtate, it was therefore neceſſary that theſe particles ſhould be endued with a property of reſuming their elastic ſtate, whenever they were diſengaged from that maſs in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and diſſolution of vegetables as well as animal bodies.

The air is very instrumental in the production and growth of vegetables, both by invigorating their ſeveral juices, while in an elastic active ſtate, and alſo by greatly contributing in a fixed ſtate, to the union and firm connexion of the ſeveral conſtituent parts of thoſe bodies, viz. their water, fire, ſalt, and earth.

To conclude, by reaſon of thoſe properties of the air before-mentioned, it is very ſerviceable to vegetables, in that it blows up and breaks open the clouds, thoſe treaſures of rain, which fertilize the vegetable kind.

The air alſo helps to waſt or diſperſe thoſe foggy humid vapours which ariſe from the earth, and would otherwiſe ſtagnate, and poiſon the whole face of the earth.

The air, by the aſſiſtance of the ſun, aſſumes and ſublimates thoſe vapours into the upper regions; and theſe foggy humid vapours are, by this ſublimation, and the coercive power of the air and ſun, rarefied and made of ſecond uſe in vegetation.

And on the contrary, to the benign quality of the air, which is ſo many ways ſubſervient to vegetables, it is alſo ſometimes, and upon ſome accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts above, but alſo to the roots and fibres below: for in that the air penetrates

into the earth, it is eaſy to be concluded, that a dry, huſky, ſcorching air, may be very prejudicial to the tender fibres of new planted trees.

It may be likewiſe ſuppoſed, that all bodies of earth are more or leſs capable of imbibing the fluid air, and of attracting ſuch ſalts as either the air can give, or the earth is capable of receiving.

AIZOON. Sempervive.

This name Dr. Linnæus has given to a plant near of kin to the Ficoides, which has been called Ficoidea, by ſome modern botaniſts.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is cut into five acute ſegments at the top: there are no petals in the flower, but the five-cornered germen reſts on the empalement, ſupporting five ſtyles, which are crowned with ſimple ſtigma; theſe are attended by many hairy ſtamina, which are inserted into the empalement, and are crowned with ſimple ſummits. The germen afterward becomes a ſwelling five-cornered capſule, having five cells, in which are lodged many roundiſh ſeeds.

This genus of plants is by Dr. Linnæus ranged in the fifth diviſion of his twelfth claſs, entitled Icoſandria Pentagynia; the flowers of this claſs having more than nineteen ſtamina, and in this diviſion they have five ſtyles.

The SPECIES are,

1. AIZOON (*Canarienſe*) foliis cuneiformi-ovatis floribus ſeſſilibus. Hort. Upſal. 127. *Sempervive with oval wedge-shaped leaves, and flowers without foot-ſtalks. Ficoidea procumbens portulacæ folio. Niſſol. Act. Par. 1711.*
2. AIZOON (*Hiſpanicum*) foliis lanceolatis floribus ſeſſilibus. Lin. Sp. Plant. 488. *Sempervive with ſpear-shaped leaves and flowers, having no foot-ſtalks. Ficoidea Hiſpanica annua folio longiore. Hort. Elth. 143.*
3. AIZOON (*Paniculatum*) foliis lanceolatis floribus paniculatis. Lin. Sp. Pl. 448. *Sempervive with ſpear-shaped leaves and flowers growing in panicles. Aizoon foliis lanceolatis ſubtus hirsutis. Prod. Leyd. 221.*

As we have no Engliſh names for theſe plants, ſo I have adopted this of Sempervive, which hath been applied to the Aloe and Sedum, both which have been alſo titled Aizoon and Sempervivum.

The firſt ſort is a native of the Canary Iſlands: this is an annual plant, which muſt be raiſed on a moderate hot-bed in the ſpring; and when the plants are fit to tranſplant, they ſhould be carefully taken up, and planted each into a ſmall pot filled with freſh light earth, and plunged into another moderate hot-bed, obſerving to ſhade them from the ſun until they have taken freſh root; after which they muſt be hardened by degrees to bear the open air, into which they ſhould be removed in June, placing them in a ſheltered ſituation, where they will flower, and ripen their ſeeds in September, ſoon after which the plants will periſh.

The ſecond ſort grows naturally in Spain; this is alſo an annual plant, whoſe branches trail on the ground; the flowers have no beauty, ſo theſe plants are only preſerved by thoſe who are curious in collecting rare plants for the ſake of variety.

The third ſort grows naturally at the Cape of Good Hope, from whence the ſeeds were brought to Europe. This is alſo of humble growth, and periſhes ſoon after the ſeeds are ripe.

Theſe may be propagated in the ſame manner as the firſt, and when the plants have acquired ſtrength, they may be planted in the full ground; but they require a poor ſandy ſoil, for in rich ground they will grow very luxuriant in branches, but will not flower till late in the ſeaſon, ſo rarely perfect their ſeeds; but when they are planted in dry ſand, or lime rubbiſh, they will be more productive of flowers, and leſs vigorous in their branches.

A L A is the hollow of a ſtalk, which either the leaf, or the pedicle of the leaf, makes with the ſtalk or branches; or it is that hollow ſinus placed between the ſtalk or branch and leaf, from whence a new offſpring is wont to put forth, which the French call,

Aiffelles

Alfelles des Plantes. Sometimes it is used for leaves which consist of many lobes or wings.

Alæ is also used to signify those petals of papilionaceous flowers placed between the Vexillum and the Carina, which the French call, *Les Ailes des Fleurs legumineuses.*

Alæ is also used for those extreme slender membranaceous parts of certain seeds; as is the Bignonia Plumeria, the fruit of the Maple, &c. which the French call *Semences ailées.* Again,

Alæ is used for those foliaceous membranes which run the whole length of the stem; whence it is called, *Caulis alatus*, a winged stalk; in French, *Tige ailée*; but modern writers have styled these *foliis decurrentibus*, or running leaves, because these alæ or wings are connected with the leaves.

ALABASTRA, are those green herbaceous leaves that encompass flowers. Jungius explains Alabastrum to be the globe, or roundish bud, that is but just peeping out.

ALATERNOIDES. See **PHYLICA**, **CLUTIA**, and **CEANOTHUS**.

ALATERNUS [called *Ἐλαιόπριον*, as though of *ἐλαία*, an Olive, and *πρίον*, an Ilex], or evergreen Privet.

The CHARACTERS are,

It hath male and female flowers in different plants in some species, and in others both sorts of flowers on the same. The male flowers are composed of an empalement of one leaf, which is funnel-shaped, and cut into five segments at their brim; to the sides of the empalement are fixed five small petals; at the base of these petals are fastened so many stamina, which are crowned with round summits. The female flowers have a great resemblance to the male, but have no stamina. In the center is placed the germen, supporting a trifid style crowned by a round stigma, the germen afterward becomes a soft round berry, containing three seeds.

Dr. Linnæus has joined this genus to the Rhamnus, to which he has also added the Frangula, Paliurus, and Zizyphus, and ranges them in his fifth class of plants, entitled Pentandria Monogynia.

The SPECIES are,

1. **ALATERNUS** (*Phyllica*) foliis ovatis marginibus crenatis glabris. Common Alaternus, with smooth leaves indented on their edges. Alaternus, 1 Clus. Hisp. 56.
2. **ALATERNUS** (*Glabra*) foliis subcordatis ferratis glabris. Alaternus with heart-shaped smooth leaves, which are sawed on their edges. Alaternus minore folio. Tourn. Inst. 595.
3. **ALATERNUS** (*Angustifolia*) foliis lanceolatis profundè ferratis glabris. Alaternus with smooth spear-shaped leaves, which are deeply sawed. Alaternus monspeliaca foliis profundius incis. H. R. Par.
4. **ALATERNUS** (*Latifolia*) foliis ovato-lanceolatis integerrimis glabris. Alaternus with smooth oval spear-shaped leaves, which are entire. Alaternus Hispanica latifolia. Tourn. Inst. 596.

The varieties of these plants are, the first sort with variegated leaves, which is commonly called Bloatched Phillyrea by the nursery gardeners. And the third sort with leaves striped with white, and another with yellow; these are known by the Silver and Gold striped Alaternus: but as these are accidental varieties, I have omitted placing them among the number of species.

The common distinction of this genus from the Phillyrea, is in the position of their leaves, which in the plants of this are placed alternately on the branches, whereas those of Phillyrea are placed by pairs opposite; this is obvious at all seasons, but there are more essential differences in their characters, as will be explained under the article Phillyrea.

The first sort has been long cultivated in the English gardens, but the plain sort is now uncommon here; for the bloatched-leaved sort has been generally cultivated in the nurseries, and the other has been almost totally neglected.

These plants were much more in request formerly than they are at present, when they were planted

against walls in court-yards to cover them, as also to form evergreen hedges in gardens, for which purpose these were improper; for their branches shoot very vigorously, and being very pliant, they are frequently displaced by the wind; and in winter, when much snow falls in still weather, the weight of that which lodges on the hedges, frequently breaks them down: add to this the trouble of keeping them in order, which cannot be effected with less than three times clipping in a season, which is not only expensive, but also occasions a great litter in a garden: these inconveniencies have justly brought these hedges into disesteem.

The third sort with silver-striped leaves, was also in great request some years ago, for planting against out-houses, and other buildings, to hide the brick-work; but as these required to be often clipped, and their branches frequently wanting to be fastened up to the wall, which was troublesome and expensive, and this sort of wall hedges being great harbour for vermin, there has been of late but little demand for these plants. The sort with gold-striped leaves is pretty rare in the English gardens, and is not so hardy as that with silver stripes, so that in severe winters they are often killed. But the taste for these variegated plants is almost lost in England, there being few persons now, who do not prefer the plain green leaves to those which are striped.

The second sort was formerly in the English gardens, in much greater plenty than at present. This was generally called Celastrus, or Staff-tree. The leaves of this sort are placed at greater distances than those of the first, so that their branches appear thinly covered with them, which may have occasioned their being disesteemed. The leaves of this are shorter than those of the first sort, and are rounded at their foot-stalks somewhat like a heart-shaped leaf, the edges are also sawed.

The third sort has been an old inhabitant in some gardens, but was not much propagated till of late years; the leaves of this are much longer and narrower than those of either of the other sorts, and the serratures on their edges are much deeper; this shoots its branches more erect, and forms an handsomer bush than any of the other, and is equally hardy, so may be allowed to have a place in all plantations of Evergreens. This grows naturally in the south of France, where the berries are gathered, and sold by the name of Avignon berries, for the use of painters, &c. for making a yellow pigment.

These sorts are by some supposed to be only varieties and not distinct species; but from many repeated trials, in raising them from seeds, I can affirm they do not vary, the seeds constantly producing the same species as they were taken from.

The second sort grows naturally about Turin, from whence I have been supplied with the seeds.

All these sorts are easily propagated by laying their branches down, as is practised for many other trees. The best time for this is in the autumn, and if properly performed, the layers will have made good roots by the autumn following, when they may be cut off from the old stock, and planted either into the nursery, or in the places where they are designed to remain. When they are planted in a nursery, they should not remain there longer than a year or two; for as they shoot their roots to a great distance on every side, so they cannot be removed after two or three years growth, without cutting off great part of them, which is very hurtful to the plants, and will greatly retard their growth, if they survive their removal; but they are frequently killed by transplanting, when they have stood long in a place. They may be transplanted either in the autumn or the spring, but in dry land the autumn planting is best, whereas in moist ground the spring is to be preferred.

The plain sorts may also be propagated by sowing their berries, which they produce in great plenty, but the birds are greedy devourers of them; so that unless the berries are guarded from them, they will soon be

June, it continued in a resorbing state, so as to resorb 13 cubic inches: that there were at that season many hot days, with much thunder and lightning, which destroys the elasticity of the air: there were generated in all 489 cubic inches, of which 48 were absorbed. The liquor was at last vapid.

On the 10th of August, 26 cubic inches of Apples being mashed, they generated 986 cubic inches of air in 13 days time, which is a quantity equal to 48 times their bulk; after which they resorbed a quantity equal to their bulk, in three or four days, notwithstanding the weather was then very hot; after which time they were stationary for many days, neither generating nor absorbing.

From which before-mentioned experiments on Raisins and ale, the ingenious author concludes, that wine and ale do not turn vapid in warm weather by imbibing the air, but by fermenting and generating too much; by which means they are deprived of their enlivening principle the air: for which reason, these liquors are best preserved in cool cellars, whereby this active invigorating principle is kept within due bounds; which when they exceed, wines are upon the fret, and are in danger of being spoiled.

Upon these, and many other experiments, which the learned author has given in his aforesaid treatise, he observes, that this air which arises in so great quantities from fermenting and dissolving vegetables, is true permanent air; which is certain, by its continuing in the same expanded and elastic state for many weeks and months; which expanded watery vapours will not do, but soon condense when cold.

Upon the whole, he concludes, that air abounds in vegetable substances, and bears a considerable part in them: and if all the parts of matter were only endowed with a strongly attracting power, all nature would then immediately become one unactive cohering lump.

Wherefore it was absolutely necessary, in order to the actuating this vast mass of attracting matter, that there should be every where mixed with it a due proportion of strongly-repelling elastic particles, which might enliven the whole mass by the incessant action between them and the attracting particles.

And since these elastic particles are continually in great abundance reduced by the power of the strong attracters, from an elastic to a fixed state, it was therefore necessary that these particles should be endued with a property of resuming their elastic state, whenever they were disengaged from that mass in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and dissolution of vegetables as well as animal bodies.

The air is very instrumental in the production and growth of vegetables, both by invigorating their several juices, while in an elastic active state, and also by greatly contributing in a fixed state, to the union and firm connexion of the several constituent parts of those bodies, viz. their water, fire, salt, and earth.

To conclude, by reason of those properties of the air before-mentioned, it is very serviceable to vegetables, in that it blows up and breaks open the clouds, those treasures of rain, which fertilize the vegetable kind.

The air also helps to waft or disperse those foggy humid vapours which arise from the earth, and would otherwise stagnate, and poison the whole face of the earth.

The air, by the assistance of the sun, assumes and sublimates those vapours into the upper regions; and these foggy humid vapours are, by this sublimation, and the coercive power of the air and sun, rarefied and made of second use in vegetation.

And on the contrary, to the benign quality of the air, which is so many ways subservient to vegetables, it is also sometimes, and upon some accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts above, but also to the roots and fibres below: for in that the air penetrates

into the earth, it is easy to be concluded, that a dry, husky, scorching air, may be very prejudicial to the tender fibres of new planted trees.

It may be likewise supposed, that all bodies of earth are more or less capable of imbibing the fluid air, and of attracting such salts as either the air can give, or the earth is capable of receiving.

AIZOON. Sempervive.

This name Dr. Linnæus has given to a plant near of kin to the Ficoides, which has been called Ficoidea, by some modern botanists.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is cut into five acute segments at the top: there are no petals in the flower, but the five-cornered germen rests on the empalement, supporting five styles, which are crowned with simple stigma; these are attended by many hairy stamina, which are inserted into the empalement, and are crowned with simple summits. The germen afterward becomes a swelling five-cornered capsule, having five cells, in which are lodged many roundish seeds.

This genus of plants is by Dr. Linnæus ranged in the fifth division of his twelfth class, entitled Icolandria Pentagynia; the flowers of this class having more than nineteen stamina, and in this division they have five styles.

The SPECIES are,

1. AIZOON (*Canariense*) foliis cuneiformi-ovatis floribus sessilibus. Hort. Upsal. 127. *Sempervive with oval wedge-shaped leaves, and flowers without foot-stalks. Ficoidea procumbens portulacæ folio. Nissol. Act. Par. 1711.*
2. AIZOON- (*Hispanicum*) foliis lanceolatis floribus sessilibus. Lin. Sp. Plant. 488. *Sempervive with spear-shaped leaves and flowers, having no foot-stalks. Ficoidea Hispanica annua folio longiore. Hort. Elth. 143.*
3. AIZOON (*Paniculatum*) foliis lanceolatis floribus paniculatis. Lin. Sp. Pl. 448. *Sempervive with spear-shaped leaves and flowers growing in panicles. Aizoon foliis lanceolatis subtus hirsutis. Prod. Leyd. 221.*

As we have no English names for these plants, so I have adopted this of Sempervive, which hath been applied to the Aloe and Sedum, both which have been also titled Aizoon and Sempervivum.

The first sort is a native of the Canary Islands: this is an annual plant, which must be raised on a moderate hot-bed in the spring; and when the plants are fit to transplant, they should be carefully taken up, and planted each into a small pot filled with fresh light earth, and plunged into another moderate hot-bed, observing to shade them from the sun until they have taken fresh root; after which they must be hardened by degrees to bear the open air, into which they should be removed in June, placing them in a sheltered situation, where they will flower, and ripen their seeds in September, soon after which the plants will perish.

The second sort grows naturally in Spain; this is also an annual plant, whose branches trail on the ground; the flowers have no beauty, so these plants are only preserved by those who are curious in collecting rare plants for the sake of variety.

The third sort grows naturally at the Cape of Good Hope, from whence the seeds were brought to Europe. This is also of humble growth, and perishes soon after the seeds are ripe.

These may be propagated in the same manner as the first, and when the plants have acquired strength, they may be planted in the full ground; but they require a poor sandy soil, for in rich ground they will grow very luxuriant in branches, but will not flower till late in the season, so rarely perfect their seeds; but when they are planted in dry sand, or lime rubbish, they will be more productive of flowers, and less vigorous in their branches.

A L A is the hollow of a stalk, which either the leaf, or the pedicle of the leaf, makes with the stalk or branches; or it is that hollow sinus placed between the stalk or branch and leaf, from whence a new offspring is wont to put forth, which the French call,

Aisselles

Affelles des Plantes. Sometimes it is used for leaves which consist of many lobes or wings.

Alæ is also used to signify those petals of papilionaceous flowers placed between the Vexillum and the Carina, which the French call, *Les Ailes des Fleurs legumineuses*.

Alæ is also used for those extreme slender membranaceous parts of certain seeds; as is the Bignonia Plumeria, the fruit of the Maple, &c. which the French call *Semences ailées*. Again,

Alæ is used for those foliaceous membranes which run the whole length of the stem; whence it is called, *Caulis alatus*, a winged stalk; in French, *Tige ailée*: but modern writers have styled these *foliis decurrentibus*, or running leaves, because these alæ or wings are connected with the leaves.

ALABASTRA, are those green herbaceous leaves that encompass flowers. Jungius explains Alabastrum to be the globe, or roundish bud, that is but just peeping out.

ALATERNOIDES. See **PHYLICA**, **CLUTIA**, and **CEANOTHUS**.

ALATERNUS [called *ἑλαιόπρινος*, as though of *ελαια*, an Olive, and *πρινος*, an Ilex], or evergreen Privet.

The CHARACTERS are,

It hath male and female flowers in different plants in some species, and in others both sorts of flowers of the same. The male flowers are composed of an empalement of one leaf, which is funnel-shaped, and cut into five segments at their brim; to the sides of the empalement are fixed five small petals; at the base of these petals are fastened so many stamina, which are crowned with round summits. The female flowers have a great resemblance to the male, but have no stamina. In the center is placed the germen, supporting a trifid style crowned by a round stigma, the germen afterward becomes a soft round berry, containing three seeds.

Dr. Linnæus has joined this genus to the Rhamnus, to which he has also added the Frangula, Paliurus, and Zizyphus, and ranges them in his fifth class of plants, entitled Pentandria Monogynia.

The SPECIES are,

1. **ALATERNUS** (*Phyllica*) foliis ovatis marginibus crenatis glabris. Common Alaternus, with smooth leaves indented on their edges. Alaternus, 1 Clus. Hisp. 56.
2. **ALATERNUS** (*Glabra*) foliis subcordatis ferratis glabris. Alaternus with heart-shaped smooth leaves, which are sawed on their edges. Alaternus minore folio. Tourn. Inst. 595.
3. **ALATERNUS** (*Angustifolia*) foliis lanceolatis profundè ferratis glabris. Alaternus with smooth spear-shaped leaves, which are deeply sawed. Alaternus monspeliaca foliis profundius incis. H. R. Par.
4. **ALATERNUS** (*Latifolia*) foliis ovato-lanceolatis integerrimis glabris. Alaternus with smooth oval spear-shaped leaves, which are entire. Alaternus Hispanica latifolia. Tourn. Inst. 596.

The varieties of these plants are, the first sort with variegated leaves, which is commonly called Bloatched Phillyrea by the nursery gardeners. And the third sort with leaves striped with white, and another with yellow; these are known by the Silver and Gold striped Alaternus: but as these are accidental varieties, I have omitted placing them among the number of species.

The common distinction of this genus from the Phillyrea, is in the position of their leaves, which in the plants of this are placed alternately on the branches, whereas those of Phillyrea are placed by pairs opposite; this is obvious at all seasons, but there are more essential differences in their characters, as will be explained under the article Phillyrea.

The first sort has been long cultivated in the English gardens, but the plain sort is now uncommon here; for the bloatched-leaved sort has been generally cultivated in the nurseries, and the other has been almost totally neglected.

These plants were much more in request formerly than they are at present, when they were planted

against walls in court-yards to cover them, as also to form evergreen hedges in gardens, for which purpose these were improper; for their branches shoot very vigorously, and being very pliant, they are frequently displaced by the wind; and in winter, when much snow falls in still weather, the weight of that which lodges on the hedges, frequently breaks them down: add to this the trouble of keeping them in order, which cannot be effected with less than three times clipping in a season, which is not only expensive, but also occasions a great litter in a garden: these inconveniencies have justly brought these hedges into disesteem.

The third sort with silver-striped leaves, was also in great request some years ago, for planting against out-houses, and other buildings, to hide the brick-work; but as these required to be often clipped, and their branches frequently wanting to be fastened up to the wall, which was troublesome and expensive, and this sort of wall hedges being great harbour for vermin, there has been of late but little demand for these plants. The sort with gold-striped leaves is pretty rare in the English gardens, and is not so hardy as that with silver stripes, so that in severe winters they are often killed. But the taste for these variegated plants is almost lost in England, there being few persons now, who do not prefer the plain green leaves to those which are striped.

The second sort was formerly in the English gardens, in much greater plenty than at present. This was generally called Celastrus, or Staff-tree. The leaves of this sort are placed at greater distances than those of the first, so that their branches appear thinly covered with them, which may have occasioned their being disesteemed. The leaves of this are shorter than those of the first sort, and are rounded at their foot-stalks somewhat like a heart-shaped leaf, the edges are also sawed.

The third sort has been an old inhabitant in some gardens, but was not much propagated till of late years; the leaves of this are much longer and narrower than those of either of the other sorts, and the serratures on their edges are much deeper; this shoots its branches more erect, and forms an handsomer bush than any of the other, and is equally hardy, so may be allowed to have a place in all plantations of Evergreens. This grows naturally in the south of France, where the berries are gathered, and sold by the name of Avignon berries, for the use of painters, &c. for making a yellow pigment.

These sorts are by some supposed to be only varieties and not distinct species; but from many repeated trials, in raising them from seeds, I can affirm they do not vary, the seeds constantly producing the same species as they were taken from.

The second sort grows naturally about Turin, from whence I have been supplied with the seeds.

All these sorts are easily propagated by laying their branches down, as is practised for many other trees. The best time for this is in the autumn, and if properly performed, the layers will have made good roots by the autumn following, when they may be cut off from the old stock, and planted either into the nursery, or in the places where they are designed to remain. When they are planted in a nursery, they should not remain there longer than a year or two; for as they shoot their roots to a great distance on every side, so they cannot be removed after two or three years growth, without cutting off great part of them, which is very hurtful to the plants, and will greatly retard their growth, if they survive their removal; but they are frequently killed by transplanting, when they have stood long in a place. They may be transplanted either in the autumn or the spring, but in dry land the autumn planting is best, whereas in moist ground the spring is to be preferred.

The plain sorts may also be propagated by sowing their berries, which they produce in great plenty, but the birds are greedy devourers of them; so that unless the berries are guarded from them, they will soon be

be devoured when they begin to ripen. The plants which arise from seeds, always grow more erect than those which are propagated by layers, so are fitter for large plantations, as they may be trained up to stems, and formed more like trees; whereas the layers are apt to extend their lower branches, which retards their upright growth, and renders them more like shrubs. They will grow to the height of eighteen or twenty feet, if their upright shoots are encouraged; but to keep their heads from being broken by wind or snow, those branches which shoot irregular should be shortened, which will cause their heads to be closer, and not in so much danger.

All the sorts thrive best in a dry, gravelly, or sandy soil, for in rich ground they are often injured by frost, when the winters are severe, but in rocky dry land they are seldom injured: and if in very hard frost their leaves are killed, yet the branches will remain unhurt, and will put out new leaves in the spring.

A L B U C A, Bastard Star of Bethlehem.

The CHARACTERS are,

The flower has no empalement; it has six oblong oval petals, which are permanent; the three outer spread open, and the three inner are connected: it hath six three-cornered stamina the length of the corolla, three of which are fertile, crowned with moveable summits, the other three, which are barren, have no summits. The nectarium is situated near the base of the three fertile stamina; it has an oblong three-cornered germen, with a broad triangular style, crowned by a pyramidal three-cornered stigma; the capsule is three-cornered, having three cells filled with small plain seeds.

This genus is ranged in the first section of Linnæus's sixth class of plants, the flower having six stamina and one style.

The SPECIES are,

1. ALBUCA (Major) foliis lanceolatis. Lin. Sp. 438. *Star flower with spear-shaped leaves.* Ornithogalum luteo-virens. Indicum. Corn. Canad.
2. ALBUCA (Minor) foliis subulatis. Lin. Sp. 438. *Star-flower with awl-shaped leaves.* Ornithogalum Africanum, flore viridi altero alteri innato. Herm. Parad. 209. *African Star-flower with a greenish yellow flower.* These plants have been generally ranged under the genus of Ornithogalum, but as their flowers differ in their form from the other species of that genus, Dr. Linnæus has constituted this genus for them.

The first sort grows naturally in Canada, and in some other parts of North America; the root is bulbous, from which shoot up eight or ten long narrow spear-shaped leaves. In the center of these arise a flower-stem a foot or more in height, garnished with a loose spike (or thyrse) of greenish yellow flowers, each have a long pedunculus, which turns downward, having pretty large stipulæ at their base, which are erect, and end in sharp points. After the flower is past, the germen swells to a three-cornered capsule, having three cells filled with flat seeds.

The second sort grows naturally at the Cape of Good Hope; this hath also a pretty large bulbous root, from which arise four or five narrow awl-shaped leaves, of a deep green colour: the flower-stem which comes from the center of the root, is naked, and rarely rises more than eight or nine inches high, having five or six greenish yellow flowers growing almost in form of an umbel at the top: these are rarely succeeded by seeds in England.

The Canada Albuca is hardy, so the roots may be planted about four inches deep in a border of light earth, where they will thrive, and produce their flowers late in the summer; but as the seeds rarely ripen in England, and the bulbs do not put out many off-sets, the plants are not common in this country.

The African sort I raised from seeds a few years past; this generally flowers twice a year, the first time in March or April, and again in July or August, but has not produced any seeds. If the roots of this sort are kept in pots, filled with light earth, and are sheltered under a hot-bed frame in winter, they will thrive and produce flowers; but the best method is to have

a border in the front of a green-house, or stove, where the roots of most of the bulbous flowers may be planted in the full ground, and screened in winter from frost; in such situations they thrive much better, and flower stronger, than when kept in pots.

A L C E A. Lin. Gen. 750. The Hollyhock.

The CHARACTERS are,

The flower hath a double empalement, of which one is permanent. The outer one is spread open, and cut at the top into six segments; the inner is larger, and slightly cut into five. The flower is composed of five petals, which coalesce at their base, and spread open at the top in form of a rose. In the center is placed the round germen, supporting a short cylindrical style, crowned with numerous stigma, which is attended by many stamina joined below to the pentagonal column, and spread open at top; these are crowned with kidney-shaped summits: after the flower is past, the germen becomes a round, depressed, articulated capsule, having many cells, in each of which is lodged one compressed kidney-shaped seed.

This genus is ranged by Dr. Linnæus in his sixteenth class of plants, entitled Monadelphia Polyandria: in this class the stamina and style coalesce and form a sort of column in the center of the flower, from whence Dr. Van Royen has given to this class the title of Columnifera, and in this division there are a great number of stamina.

The SPECIES are,

1. ALCEA (Rosea) foliis sinuatis angulosis. Hort. Cliff. 348. *Hollyhock with angular sinuated leaves.* Malva rosea folio subrotundo. C. B. P. 315.
2. ALCEA (Ficifolia) foliis palmatis. Hort. Cliff. 348. *Hollyhock with banded leaves.* Malva rosea folio ficus; C. B. P. 315.

These are distinct species, whose difference in the form of their leaves always continues. The leaves of the first sort are roundish, and cut at their extremity into angles; whereas those of the second are deeply cut into six or seven segments, so as to resemble a hand.

The various colours of their flowers being accidental, as also the double flowers being only varieties which have risen from culture, are not by botanists deemed distinct species. I have not enumerated them here, therefore shall only mention the various colours which are commonly observed in their flowers; which are white, pale, red, deep red, blackish red, purple, yellow, and flesh colour. Besides these, I many years ago saw some plants with variegated flowers, in the garden of the late Lord Burlington, in London, raised from seeds which came from China.

Although these varieties of double Hollyhocks are not constant, yet where the seeds are carefully saved from the most double flowers, the greatest number of the plants will arise nearly the same, as the plants from which they were taken, both as to their colour and the fulness of their flowers, provided no plants with single or bad coloured flowers are permitted to grow near them. Therefore so soon as any such appear, they should be removed from the good ones, that their farina may not spread into the other flowers, which would cause them to degenerate.

The first species grows naturally in China, from whence I have often received the seeds. The second sort I have received from Istria, where it was gathered in the fields, but these seeds produced single red flowers only; whereas from some seeds of this sort, which were given me by the late Charles Du Bois, Esq; of Mitcham, in 1726, which he procured from Madras, I raised many double flowers of several colours.

These plants, although natives of warm countries, yet are hardy enough to thrive in the open air in England, and have for many years been some of the greatest ornaments in the garden, toward the latter part of summer; but since they have become very common, have not been so much regarded as they deserve, partly from their growing too large for small gardens, and their requiring tall stakes to secure them from being broken by strong winds. But in large gardens,

gardens, where they are properly disposed, they make a fine appearance; for as their spikes of flowers grow very tall, there will be a succession of them on the same stems, more than two months; the flowers on the lower part of the spike appearing in July, and as their stalks advance, new flowers are produced till near the end of September. When the plants are planted in good ground, their stalks often rise to the height of eight or nine feet, so that near six feet of each will be garnished with flowers; which when double, and of good colours, will make a fine appearance, especially if the various colours are properly intermixed.

They are propagated by seeds, which, as hath been already observed, should be carefully saved from those plants whose flowers are the most double, and of the best colours. If these are preserved in their capsules until spring, the seeds will be better, provided they are gathered very dry, and care be taken that no damp comes to them in winter, which will cause their covers to be mouldy, and thereby spoil the seeds.

The seeds should be sown on a bed of light earth, about the middle of April, which must be covered about half an inch deep, with the same light earth; some persons sow them in shallow drills, and others scatter the seeds thinly over the whole bed. When they are sown in the former method, the plants generally come up thick, so will require to be transplanted sooner than those which are sown in the latter. By the first, the seeds may be more equally covered, and kept clean with less trouble, because the ground between the drills may be hoed. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, at a foot distance from each other, observing to water them until they have taken good root; after which they will require no farther care, but to keep them clean from weeds till October, when they should be transplanted where they are to remain.

Some persons let their plants remain a year longer in the nursery-beds to see their flowers, before they remove them to the flower-garden; but when this is intended, the plants should be planted at a greater distance in the nursery-beds, otherwise they will not have room to grow. However, I have always chosen to remove my plants the first autumn, for young plants more surely grow, than those which are older; and if the seeds are carefully saved, there will not be one in ten of the plants come single or of bad colours.

ALCHEMILLA, Ladies Mantle.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is spread open at the brim, and cut into eight segments. There are no petals to the flower, but the center of the empalement is occupied by the oval germen, into which is inserted a long style, crowned with a globular stigma: this is attended by four erect stamina resting on the brim of the empalement, and crowned with roundish summits; the germen afterwards turns to a single compressed seed.

Dr. Linnæus ranges this genus in the first section of his fourth class of plants, entitled Tetrandria monogynia, the flowers having four stamina and one style.

The SPECIES are,

1. *ALCHEMILLA (Vulgaris) foliis lobatis serratis, segmentis involucri acuto. The common Ladies Mantle. C. B. P. 319.*
2. *ALCHEMILLA foliis lobatis sericeis acutè serratis, segmentis involucri subrotundis. Small silvery Ladies Mantle with lobed leaves sharply serrated, and the segments of the involucrium cut into roundish segments. Alchemilla Alpina pubescens minor. Tourn. Inst. R. H. 508.*
3. *ALCHEMILLA (Alpina) foliis digitatis serratis. Flor. Lapp. 61. Silvery Alpine Ladies Mantle with banded leaves. Alchemilla perennis incana argentea sive sericea sativum provocans. Mor. Hist. 2, p. 195.*
4. *ALCHEMILLA (Pentaphylla) foliis quinatis multifidis, glabris. Lin. Sp. Plant. 123. Smooth five-leaved Ladies Mantle, cut into many segments. Alchemilla Alpina*

pentaphylla minima lobis fimbriatis. Bocc. Musc. 1. p. 18.

The first sort grows naturally in moist meadows in several parts of England, but is not very common near London: the roots are composed of many thick fibres, which spread greatly when they are in a proper soil; the leaves rise immediately from the root, sustained by long foot-stalks; they are roundish, and scalloped round the borders into seven or eight lobes, shaped somewhat like the Ladies scalloped Mantles, from whence it had its name. The flower-stems arise between the leaves about a foot high, which divide into many branches, and are at each joint garnished with one small leaf, shaped like those below; the flowers are composed of an herbaceous empalement, in the center of which is the style attended by four stamina, crowned with yellow summits; so that the only beauty of this plant is in the leaves, which are used in medicine, and are esteemed to be vulnerary, drying and binding, and of great force to stop inward bleeding.

The second sort is much smaller than the first, the leaves are much whiter and appear silky; the flower-stems do not branch out so much, nor are the flowers produced in so large clusters: their empalement is broader, and the segments more obtuse than those of the first sort.

The third sort grows naturally on the mountains in Yorkshire, Westmoreland, and Cumberland, generally upon moist boggy places. It is also a native of Sweden and Denmark, the Alps, and other cold parts of Europe, and is admitted into gardens for the sake of variety. The leaves of this sort are very white, and deeply cut into five parts like a hand; the flower-stems seldom rise more than six inches high, nor do the flowers make a better appearance than the other sorts.

The fourth sort grows naturally in Sweden, Lapland, and other cold countries, so is only to be found in some few curious botanic gardens in this country. These are all abiding plants, which have perennial roots and annual stalks, which perish in autumn. They may be propagated by parting their roots; the best time for doing this is in the autumn, that their roots may be established before the drying winds of the spring come on. They should have a moist soil and a shady situation, otherwise they will not thrive in the southern parts of England. When they are propagated by seeds, they should be sown in the autumn; for when they are sown in the spring, they seldom grow the first year. They should be sown on a shady moist border, and when the plants come up, they will require no other care but to be kept clean from weeds.

ALDERTREE. See ALNUS.

ALETRIS.

The CHARACTERS are,

The flower has no empalement, but hath one oblong oval petal, cut into six segments at the brim, and are permanent; it hath six awl-shaped stamina the length of the corolla, whose base are inserted in the segments; these are crowned by oblong erect summits, and an oval germen supporting an awl-shaped style the length of the stamina, crowned by a trifid stigma. The germen afterward becomes an oval three-cornered capsule with three cells, filled with angular seeds.

This genus of plants is ranged in Linnæus's first section of his sixth class, the flowers having six stamina and one style.

The SPECIES are,

1. *ALETRIS (Farinosa) acaulis, foliis lanceolatis membranaceis, floribus alternis. Lin. Sp. 456. Aletris without stalks, spear-shaped membranaceous leaves, and flowers placed alternate. Hyacinthus caule nodo, foliis linguiformibus acuminatis dentatis. Flor. Virg. 38.*
2. *ALETRIS (Capensis) acaulis, foliis lanceolatis undulatis, spica ovata, floribus nutantibus. Lin. Sp. 456. Aletris without stalks, waved spear-shaped leaves, and an oval spike of alternate flowers.*

3. *ALETIS* (*Hyacinthoides*) acaulis, foliis lanceolatis car-nosis, floribus geminatis. Lin. Sp. 456. *Aletis with-out stalks, fleshy spear-shaped leaves, and flowers set by pairs.*

4. *ALETIS* (*Zeylanica*) acaulis, foliis lanceolatis planis erectis radicalibus. *Aletis without stalks, and plain, spear-shaped, erect leaves rising from the root.*

5. *ALETIS* (*Fragrans*) caulescens, foliis lanceolatis am-plexicaulibus. *Stalky Aletis, with spear-shaped leaves embracing it.* Aloe Africana arboreicens, floribus al-bis fragrantissimis. Hort. Amst. 2. tab. 4.

The first sort grows naturally in North America; it hath a tuberose root, from which arise several spear-shaped leaves, and a naked stalk supporting a spike of flowers placed alternate, of a greenish white colour; these appear in June, but are rarely succeeded by seeds in England.

This plant is tolerably hardy, so may be preserved thro' the winter, if sheltered under a hot-bed frame; but as the seeds do not ripen here, and the roots in-crease but slowly, the plants are at present rare in England.

The second sort grows naturally at the Cape of Good Hope. This is a low plant, seldom rising more than a foot high; the leaves are spear-shaped and undu-lated; the foot-stalks of the flower arise from the root, which sustain several white nodding flowers, in shape somewhat like those of the Hyacinth.

The roots of this sort must be planted in pots filled with light earth, that they may be sheltered in a dry airy glass-case in winter, being too tender to thrive in the open air in England; therefore the pots should be removed into shelter in October, and during the winter season, they should be sparingly watered. In May they should be placed abroad in a sheltered si-tuation, and in warm weather must be frequently re-freshed with water; with this management the plants will flower; but as they do not perfect their seeds here, nor do they increase fast by roots, the plants are scarce in England.

The third sort has been long preserved in the English gardens, and has been known by the title of Guinea Aloe; this hath thick fleshy roots like those of the Flag Iris, which creep far where they have room. The leaves arise singly from the root, and are near one foot and a half long, stiff, waved, and have no foot-stalks, arising immediately from the root, as do also the foot-stalks of the flowers, which when the roots are strong, are often a foot and a half high, gar-nished great part of their height with clear white flowers, shaped like those of the Hyacinth, whose brims are cut into six segments, which are reflexed; these seldom continue in beauty more than two or three days, and are never succeeded by seeds here.

The fourth sort is also pretty common, in gardens where there are conveniencies for preserving exotic plants. This hath fleshy creeping roots, which mul-tiply greatly. The whole plant seldom rises more than six inches high: the leaves are plain and upright, arising without foot-stalks; but as I have never seen any flowers produced on the plants, I can give no de-scription of them, but have followed Dr. Linnæus in ranging it, though I have great reason to believe he has not seen the flower; for he supposes this to be a variety of the third sort, which no person who is ac-quainted with the two plants can ever admit. This has been always known by the title of Ceylon Aloe.

The fifth sort rises with an herbaceous stalk to the height of eight or ten feet high, having many joints, and is adorned toward the top with a head of spear-shaped thin leaves, which are of a deep green colour and reflexed at their ends, embracing the stalks with their base. The foot-stalks of the flower arise from the center of the heads, which are generally two feet high, branching out on each side, and fully garnished with white flowers, in shape somewhat like those of the third sort; but these open only in the evening, when they emit a most fragrant odour, but close again in the morning, and are not of long duration; but these are sometimes succeeded by seeds, which, al-

though fair to appearance, yet I could never raise any plants from them; but they are easily propagated from the side heads, which they put out after flowering.

The last three sorts are too tender to live through the winter in England, unless they are placed in a warm stove; nor will the third and fifth sorts produce their flowers, if the plants are not plunged into a tan-bed; for although the plants may be preserved in a dry stove, yet those make but little progress there; where-as when they are in a tan-bed, they will advance as much in one year as the other will in three or four; the leaves will also be much larger, and the whole plant much stronger. The third sort will sometimes flower in a dry stove, but the flower-stems will be weak, and do not produce half so many flowers as when in tan; but the fifth has not yet flowered here when kept in the dry stove.

The third and fourth sorts propagate very fast by their creeping roots, which send up many heads; these may be cut off in June, and laid in the stove for a fortnight, that the part wounded may be healed over; then they should be planted in small pots, filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark, giving them but little wa-ter till they have put out good roots; then they must be treated like other tender succulent plants, never setting them abroad in summer.

The heads of the fifth sort when taken from the stems should be laid in the stove a week, for their wounds to heal, then should be planted in pots and treated as the other.

ALLIUM [of ἄλλω, Gr. to avoid or shun, because many shun the smell of it], Garlick.

The CHARACTERS are,

The flowers are included in one common spathe, which be-comes dry; the flower is composed of six oblong, erect, con-cave petals, and six awl-shaped stamina, which extend the length of the petals, and are crowned with oblong sum-mits. In the center is situated a short three-cornered ger-men, supporting a single style, crowned by an acute stigma. The germen afterward becomes an obtuse three-cornered cap-sule, opening into three parts, having three cells, filled with roundish seeds.

The SPECIES are,

1. ALLIUM (*Sativum*) caule planifolio bulbifero, bulbo composito, staminibus tricuspidatis. Hort. Upsal. 76. Common manured Garlick. Allium sativum. C. B. P.
2. ALLIUM (*Scorodoprasum*) caule planifolio bulbifero, foliis crenulatis vaginis ancipitibus staminibus tricuspidatis. Hort. Upsal. 77. The Rocambole. Allium sativum alterum sive allioprasum caulis summo cir-cumlocuto. C. B. P. 73.
3. ALLIUM (*Ursinum*) scapo nudo semicylindrico foliis lanceolatis petiolatis umbellâ fastigiata. Lin. Sp. Plant. 300. Broad-leaved wild Garlick, or Ramsons. Allium sylvestre latifolium. C. B. P.
4. ALLIUM (*Lineare*) caule planifolio umbellifero um-bellâ globosâ staminibus tricuspidatis corolla duplo longioribus. Lin. Sp. Plant. 294. Great round-headed Garlick of the Holm Islands. Allium Holmense sphæ-rico capite. Raii Syn. 370.
5. ALLIUM (*Moly*) scapo nudo subcylindrico foliis lan-ceolatis sessilibus umbellâ fastigiata. Hort. Upsal. 76. The yellow Moly. Allium latifolium luteum. Tourn. Inst. 384.
6. ALLIUM (*Magicum*) caule planifolio umbellifero ra-mulo bulbifero staminibus simplicibus. Lin. Sp. Plant. 296. Great broad-leaved Moly with Lily flowers. Allium latifolium liliflorum. Tourn. Inst. 384.
7. ALLIUM (*Obliquum*) caule planifolio umbellifero sta-minibus filiformibus flore triplo longioribus foliis ob-livis. Lin. Sp. Plant. 296. Umbelliferous Garlick with plain leaves, slender stamina, which are three times the length

length of the flower, and oblique leaves. *Allium radice tunicatâ foliis planis linearibus caulinis capitulo umbellato.* Flor. Siber. i. p. 49.

8. *ALLIUM (Ramosum)* caule subplanifolio umbellifero staminibus subulatis longioribus umbellâ globosâ foliis linearibus subconvexis. Lin. Sp. Pl. 296. *Umbelliferous Garlick with half plain leaves, long awl-shaped stamina, globular umbels, and narrow convex leaves.*
9. *ALLIUM (Roseum)* scapo nudo umbellifero, pedicellis brevibus, petalis ovalibus, staminibus brevissimis, foliis linearibus. Lin. Sp. 432. *Garlick with a naked umbelliferous stalk, short foot-stalks, oval petals to the flower, very short stamina, and linear leaves.* *Allium sylvestre* five moly minus, roseo amplo flore. Magnol. II.
10. *ALLIUM (Arenarium)* caule planifolio bulbifero vaginis teretibus spathâ muticâ staminibus tricuspidatis. H. Scan. 227. *Bulb-bearing Garlick, with plain leaves, a taper vagina, and three pointed stamina.*
11. *ALLIUM (Carinatum)* caule planifolio bulbifero staminibus subulatis. Lin. Sp. Plant. 297. *Bulb-bearing garlick with plain leaves, and awl-shaped stamina.* *Allium montanum* bicornne angustifolium flore dilutè purpurascente. C. B. P. 74.
12. *ALLIUM (Sphaerocephalon)* caule teretifolio umbellifero, foliis semiteretibus, staminibus tricuspidatis corolla longioribus. Lin. Sp. 426. *Umbelliferous Garlick, with taper leaves which are longer than the petals.* *Allium* five moly montanum purpureo flore. Clus. Hist. i. p. 195.
13. *ALLIUM (Flavum)* caule teretifolio umbellifero, floribus pendulis, petalis ovatis, staminibus corolla longioribus. Lin. Sp. 428. *Umbelliferous Garlick, with taper leaves and pendulous flowers, having oval petals, and stamina longer than the corolla.* *Allium montanum* bicornne flore pallido odore. C. B. P. 75.
14. *ALLIUM (Senescens)* scapo nudo ancipiti foliis linearibus subtus convexis lævibus umbellâ subrotundâ staminibus subulatis. Hort. Upsal. 79. *Greater Mountain Garlick with leaves like Narcissus.* *Allium montanum* foliis Narcissi majus. C. B. P. 75.
15. *ALLIUM (Angulosum)* scapo nudo ancipiti foliis linearibus canaliculatis subtus subangulatis umbellâ fastigiata. Hort. Upsal. 79. *Garlick with a naked stalk, narrow hollow leaves, which are angular on their lower side, and a compact umbel.* *Allium montanum* foliis Narcissi minus. C. B. P. 75.
16. *ALLIUM (Subhirsutum)* caule planifolio umbellifero foliis inferioribus hirsutis staminibus subulatis. Lin. Sp. Plant. 295. *Umbelliferous Garlick with hairy under leaves, and awl-shaped stamina, commonly called Dioscoridis Moly.* *Moly angustifolium umbellatum.* C. B. P. 75.
17. *ALLIUM (Villosa)* umbella rotundata, staminibus lanceolatis corolla longioribus, foliis ellipticis. Lin. Mat. Med. 163. *Umbelliferous Garlick with round umbels, spear-shaped stamina longer than the corolla, and elliptical leaves.* *Allium montanum* latifolium maculatum. C. B. P. 74.
18. *ALLIUM (Descendens)* caule subteretifolio umbellifero, pedunculis exterioribus brevioribus, staminibus tricuspidatis. Lin. Sp. 427. *Umbelliferous Garlick with a half taper leaf, and three pointed stamina.* *Allium moly* latifolium, capite sphaerico, flore purpureo. Rudb.
19. *ALLIUM (Canadense)* scapo nudo tereti, foliis linearibus capitulo bulbifero. Kalm. It. Canada *Garlick with a naked taper stalk, linear leaves, and beads bearing bulbs.* *Allium bulbiferum Virginianum.* Boerh. Ind. Alt. 2. 146.
20. *ALLIUM (Triquetrum)* scapo nudo foliis triquetris, staminibus simplicibus. Lin. Sp. 431. *Garlick with a naked stalk, triangular leaves, and simple stamina.* *Moly parvum* caule triangulo. C. B. P. 75.

We shall not bring under this genus the *Cepa* and *Porrum*, as is done by Dr. Linnæus, lest by too closely adopting his system, we may render this work less intelligible to the practical gardener, and such other persons who may delight themselves in the culture of a kitchen-garden; but not having studied the

science of botany, may not so readily turn to those articles, therefore we shall insert their culture under their former titles.

The two first species are easily propagated by planting the cloves, or small bulbs, in the spring, in beds about four or five inches distance from each other, keeping them clean from weeds. About the beginning of June, the leaves of the first sort should be tied in knots, to prevent their spindling, or running to seed, which will greatly enlarge the bulb. In the middle of July, the leaves will begin to wither and decay, at which time they should be taken out of the ground, and hanged up in a dry room, to prevent their rotting, and may be thus preserved for winter use.

The roots of the second sort may remain in the ground till the leaves are decayed, when their bulbs may be taken up and dried, to be preserved for use during the winter season; but some of the roots may be at the same time planted again for the succeeding year; for this sort requires to be planted in autumn, especially on dry ground, otherwise their bulbs will not be large.

The third sort was formerly in greater esteem than at present, it being rarely cultivated in gardens, but is found wild in moist shady places in many parts of England; and may be cultivated by planting the roots in a moist shady border, at almost any time of the year; but the best season is in July, just as the green leaves are decaying.

The fourth sort grows naturally in the Holm Islands, from whence it has been transplanted into several gardens, where it is preserved more for the sake of variety than use.

The eleventh and thirteenth sorts grow wild in the northern parts of England, but are by the curious in botany preserved in their gardens. These are very hardy, and may be removed in July or August, when their leaves begin to decay, and will thrive in almost any soil or situation.

The fifth sort was formerly preserved in gardens for the sake of its yellow flowers, but having a very strong Garlick scent, most people have rooted it out of their gardens.

The sixth sort is also preserved by many persons in their gardens for the sake of variety, but as this hath a very strong scent, so it is not often admitted to the flower-garden.

The ninth and twelfth sorts are sometimes permitted to have a place in gardens for the sake of variety.

The seventh, eighth, and tenth sorts grow naturally in Tartary and Siberia, from whence their seeds were sent to Petersburg, and from thence some of the botanic gardens have been supplied with seeds; these are only preserved for the sake of variety.

The fourteenth, fifteenth, and sixteenth sorts, have been planted in gardens for the variety of their flowers, but of late years most people have turned them out, to make room for better sorts. But the sixteenth multiplies so fast by offsets, as to render it difficult to extirpate them, when they have remained any time in a garden.

This produces large umbels of white flowers, growing on stalks about ten inches high; the time of flowering is in April and May.

The nineteenth sort was brought from Virginia, and is preserved in botanic gardens for variety's sake, but has no great beauty; it is very hardy, and will thrive in the open air very well; and is propagated by its bulbs, which are produced in plenty on the top of the stalks.

They are all of them very hardy, and will thrive in almost any soil or situation, and are easily propagated either by their roots, or from seeds: if from the roots, the best time is in autumn, that they may take good root in the ground before the spring, which is necessary, in order to have them flower strong the following summer. If they are propagated by seeds, they may be sown on a border of common earth, either in autumn, soon after the seeds are ripe, or in the spring following, and will require no farther care, but to keep

keep them clear from weeds; in the following autumn, the plants may be transplanted into the borders where they are to remain for good.

The greatest part of these plants produce their flowers in May, June, and July.

The yellow Moly will grow about a foot high; and having some beauty in the flowers, is worthy of a place in such borders of the flower-garden, where few better things will thrive. These increase plentifully both by roots and seeds.

The sixth and seventeenth sorts grow upwards of two feet high, and when they are in flower, make a pretty appearance; and as they are not troublesome to keep, may be allowed a place in the borders of the flower-garden.

All the other sorts are equally hardy, and will grow in any soil or situation; but as they have little beauty, they are rarely preserved, except in botanic gardens for the sake of variety.

ALOE [Gr. ἄλoη].

The CHARACTERS are,

The flower is naked, having no empalement; it is of one leaf, having a long smooth tube, which is divided at the top into six parts, spreading open; it hath six awl-shaped stamens, which are inserted at their base to the germen, and are extended the length of the tube; these are crowned with oblong summits; in the center is situated the oval germen, supporting a single style, which is of the same length with the stamens, crowned with a trifid stigma. The germen afterward becomes an oblong capsule, having three furrows, which is divided into three cells opening in three parts, and filled with angular seeds.

This genus of plants is by Dr. Linnæus ranged in the first section of his sixth class, titled Hexandria monogynia; from the flowers having six stamens and one style.

The SPECIES are,

1. ALOE (*Mitriformis*) floribus pedunculatis cernuis corymbosis sub-cylindricis. Lin. Sp. Plant. 319. i. e. Aloe with dependent flowers, having foot-stalks which are ranged in a cylindrical corymbus. Aloe Africana mitriformis spinosa. Hort. Elth. 1. p. 21. Mitre-shaped Aloe.
2. ALOE (*Barbadensis*) foliis dentatis erectis succulentibus subulatis, floribus luteis in thyrsis dependentibus. Aloe with erect, succulent, awl-shaped leaves, and yellow flowers growing in a loose spike, hanging downward. Aloe vulgaris. C. B. P. 386.
3. ALOE (*Arborescens*) foliis amplexicaulibus reflexis, margine dentatis, floribus cylindricis caule fruticoso. Aloe with leaves embracing the stalks, which are reflexed and indented on their edges, flowers growing cylindrical, and a shrubby stalk. Aloe Africana caulescens foliis glaucis caulem amplectantibus. H. Amst. Commonly called Sword Aloe.
4. ALOE (*Africana*) foliis latioribus amplexicaulibus, margine & dorso spinosis, floribus spicatis, caule fruticoso. Aloe with broader leaves embracing the stalks, whose edges and back are set with spines, flowers growing in spikes, and a shrubby stalk. Aloe Africana caulescens foliis minus glaucis dorso parte supremâ spinosa. Com. Præl. 68.
5. ALOE (*Disticha*) foliis latissimis amplexicaulibus maculatis, margine spinosis floribus umbellatis. Aloe with very broad spotted leaves embracing the stalk, whose edges are set with spines and flowers, growing in an umbel. Aloe Africana caulescens foliis spinosis maculis ab utraque parte albicantibus notatis. Hort. Amstel. 2. p. 9. by some called the Sope Aloe, and by others Carolina Aloe.
6. ALOE (*Obscura*) foliis latioribus amplexicaulibus maculatis margine spinosis floribus spicatis. Aloe with broad spotted leaves embracing the stalks, whose edges have spines, and flowers growing in a spike. Aloe Africana caulescens foliis spinosis maculis ab utraque parte al-

bicantibus obscurioribus magis glaucis quam præcedens. Boerh. Ind.

7. ALOE (*Plicatilis*) foliis ensiformibus inermis ancipitibus floribus laxè spicatis caule fruticoso. Aloe with sword-shaped smooth leaves, standing two ways, the flowers growing in loose spikes, and a shrubby stalk. Aloe Africana arborescens montana non spinosa folio longissimo plicatili flore rubro. Com. Hort. Amst. 2. p. 5.
8. ALOE (*Brevioribus*) foliis amplexicaulibus utraque spinosis, floribus spicatis. Aloe with leaves embracing the stalks, which are prickly on every side, and flowers growing in spikes. Aloe Africana caulescens foliis glaucis brevissimis foliorum parte internâ & externâ nonnihil spinosa. Com. Præl. 71.
9. ALOE (*Variegata*) floribus pedunculatis cernuis racemosis prismaticis ore patulo æquali. Lin. Sp. Plant. 321. Aloe with hanging flowers, having foot-stalks, and spreading equally at the brim. Aloe Africana humilis foliis ex albo & viridi variegatis. Com. Præl. 79. commonly called Partridge-breast Aloe.
10. ALOE foliis erectis subulatis radicatis undique inermes spinosis. Hort. Cliff. 131. Aloe with erect awl-shaped leaves, set with soft spines on every part. Aloe Africana humilis spinis inermibus & verrucosis obsita. Com. Præl. 77. commonly called Hedge-hog Aloe.
11. ALOE (*Viscosa*) floribus sessilibus infundibuli formibus bilabiatis laciniis quinque revolutis summa erecta. Lin. Sp. Plant. 322. Aloe with funnel-shaped flowers, without foot-stalks, opening in two lips, and cut into five segments, which turn backward, and are erect at the top. Aloe Africana erecta triangularis & triangulari folio viscoso. Com. Præl. 82.
12. ALOE (*Spiralis*) floribus sessilibus ovatis crenatis segmentis interioribus conniventibus. Lin. Sp. Plant. 322. Aloe with oval crenated flowers, without foot-stalks, and the interior segments closing together. Aloe Africana erecta rotunda folio parvo & in acumen acutissimum exeunte. Com. Præl. 83.
13. ALOE (*Linguiforme*) sessilis foliis lingui formibus maculatis floribus pedunculatis cernuis. Aloe with dwarf, tongue-shaped, spotted leaves, and hanging flowers, which have foot-stalks. Aloe Africana flore rubro folio maculis albicantibus ab utraque parte notato. H. Amst. 2. p. 15. commonly called Tongue Aloe.
14. ALOE (*Margaritifera*) floribus sessilibus bilabiatis labio superiore erecto inferiore patente. Lin. Sp. Plant. 322. Aloe with sessile flowers, gaping with two lips, the upper being erect, and the under spreading. Aloe Africana folio in summitate triangulari margaritifera flore subviridi. Com. Hort. Amst. 2. p. 19. commonly called large Pearl Aloe.
15. ALOE (*Vera*) foliis longissimis & angustissimis marginibus spinosis, floribus spicatis. Aloe with very long narrow leaves, having spines on their hedges, and flowers growing in spikes. Aloe Indiæ Orientalis, ferrata succotrina vera flore Phœnicio. Hort. Beaumont. The Succotrine Aloe.
16. ALOE (*Glaucæ*) caule brevi, foliis amplexicaulibus bifariam versis spinis marginibus erectis floribus capitis. Aloe with a short stalk, leaves standing two ways, which embrace the stalk; the spines on the edges erect, and flowers growing in a head. Aloe Africana caulescens foliis glaucis brevioribus foliorum parte internâ & externâ nonnihil spinosa. Com. Præl. 71.
17. ALOE (*Arachnoidea*) sessilis foliis brevioribus planis carnosus apice triquetris marginibus inermes spinosis. Low Aloe with short, plain, fleshy leaves, triangular at their ends, and borders set with soft spines. Aloe Africana humilis arachnoidea. Com. Præl. 72. commonly called Cobweb Aloe.
18. ALOE (*Herbacea*) foliis ovato-lanceolatis carnosus apice triquetris angulis inermes dentatis. Hort. Cliff. 131. Aloe with oval, spear-shaped, fleshy leaves, having three angles at their extremities, which are indented and set with soft spines. Aloe Africana minima atro-viridis spinis herbaceis numerosis ornata. Boerh. Ind. Alt. 2. p. 131.
19. ALOE (*Retusa*) floribus sessilibus triquetris bilabiatis labio inferiore revolutis. Lin. Sp. Plant. 322. Aloe with flowers divided into three parts, the under lip being turned

turned back. Aloe Africana brevissimo crassissimoque folio flore subviridi. Hort. Amst. 2. p. 11. commonly called Cushion Aloe.

20. ALOE (*Verrucosa*) sessilis foliis carinatis utraque verrucosis bifariam versis. *Low Aloe with keel-shaped leaves, warted on every part, and standing two ways.* Aloe Africana foliis longis conjugatis supra cavis margariferis flore rubro elegantissimo. Boerh. Ind. Alt. p. 2; 131. commonly called Pearl-tongue Aloe.

21. ALOE (*Carinata*) sessilis foliis carinatis verrucosis apice triquetris carnosus. *Low Aloe with fleshy, keel-shaped, spotted leaves, which are triangular at their extremities.* This is the Aloe Africana flore rubro folio triangulari verrucis & ab utraque parte albicantibus notato. Hort. Amst. 2. p. 17.

22. ALOE (*Ferox*) foliis amplexicaulibus nigricantibus undique spinosis. *Aloe with dark green leaves embracing the stalks, which are beset with spines on every side.* Aloe vera costa spinosa. Munt. Phyt. commonly called Aloe ferox.

23. ALOE (*Uvaria*) floribus sessilibus reflexis imbricatis prismaticis. Lin. Sp. Plant. 323. *Aloe with reflexed flowers growing close to the stalk, in form of a prism, lying over each other like tiles on a house.* Aloe Africana folio triangulari longissimo & angustissimo floribus luteis foetidis. Hort. Amst. 2. p. 29. commonly called Iris Uvaria.

The first sort of Aloe grows with an upright stalk, to the height of five or six feet, the leaves closely embrace the stalks; they are thick; succulent, broad at their base, growing narrower, and ending in a point, of a dark green colour, and have spines on the edges, as also a few on their upper surface; the leaves stand erect, and draw together towards the top, where they form the resemblance of a mitre, from whence it is called the Mitre Aloe. The flower-stem rises about three feet high, on the top of which the flowers come out in a sort of globular spike, but afterwards is formed into a cylindrical spike: these have long foot-stalks, which come out horizontally, and the flowers hang downward; they are tubulous, and cut into six unequal segments to the bottom, three being alternately broader than the others. There are six stamens, three of which are as long as the tube of the flower, the other three are shorter. These are crowned with flat oblong summits of a gold colour. The three-cornered germen is situated in the bottom of the flower, supporting a single style, which is shorter than the stamens, having no stigma on the top. The tube of the flower is of a fine red colour, and the brim is of a pale green, so that it makes a pretty appearance when the spikes of flowers are large.

This sort will live in a warm dry green-house in winter, and may be placed in the open air in summer, in a sheltered situation; but the plants should not have much wet, lest it should rot their stems. With this management the plants will not grow so fast, as when they are placed in a stove, but they will be stronger, and their stems will support their heads much better.

The second sort is very common in the islands of America, where the plants are propagated upon the poorest land, to obtain the Hepatic Aloes, which are brought to England, and used chiefly for horses, being too coarse for medicine.

The leaves of this sort are about four inches broad at their base, where they are near two inches thick, and diminish gradually to a point, having a few indentures on their edges; the leaves are of a sea-green colour, and when young are spotted with white. The flower-stem rises near three feet high, and the flowers stand in a slender loose spike, with very short foot-stalks, hanging downwards. They are tubulous, and cut into six parts, of a bright yellow colour, and the stamens stand out beyond the tube. This never produces seed in England, and is too tender to live through the winter in our climate, in a common green-house, therefore it should be placed in a moderate degree of warmth in that season. I have known plants of this kind, which have had an oiled cloth tied about

their roots, and hung up in a warm room more than two years, and afterwards planted in pots, which have grown very well, from whence the plant has been called Sempervivum by the inhabitants of America.

The third sort will grow to the height of ten or twelve feet, with a strong naked stem, the leaves growing at the top, which closely embrace the stalk; they are about two inches broad at their base, growing narrower to a point, and are reflexed, and indented on their edges, each being armed with a strong crooked spine. The leaves are of a sea-green colour, and very succulent. The flowers grow in a pyramidal spike, are tubulous, and of a bright red colour. These are in beauty in November and December.

This sort will live through the winter in a good green-house, but they will not flower unless they have a moderate share of warmth, therefore the pots should be removed into a stove in October, which should not be kept above temperate heat, in which situation they seldom fail to flower.

The fourth sort is somewhat like the third, but the leaves are broader, and have several spines on their backside toward their extremities. The flowers of this grow in a looser spike, and the plants never put out any suckers, so that it is very difficult to increase.

The fifth sort seldom rises much above two feet high; the leaves are very broad at their base, where they closely embrace the stalk, and gradually decrease to a point. The edges are set with sharp spines, and the under leaves spread open horizontally every way; these are of a dark green colour spotted with white, somewhat resembling the colour of soft sope, from whence some have given it the title of Sope Aloe. The flowers grow in umbels on the tops of the stalks, which are of a beautiful red colour, and appear in August and September. This sort is hardy, so may be kept in a common green-house in winter, and in the summer placed in the open air.

The sixth sort is somewhat like the fifth in its manner of growth, but the leaves are broader, of a lighter green colour; the edges and also the spines are of a copper colour, and the flowers grow in loose spikes. This is as hardy as the former, so may be treated in the same manner. It flowers in September.

The seventh sort grows to the height of six or seven feet, with a strong stem, toward the upper part of which are produced two, three, or four heads, composed of long, compressed, pliable leaves, of a sea-green colour, entire, and ending in obtuse points; these are placed two ways, lying over each other with their edges the same way. The flowers are produced in short loose spikes, which are of a red colour, and appear at different times of the year.

The eighth sort is an humble plant, seldom rising more than a foot high; the leaves grow near the ground, which are broad at their base, where they embrace the stalk, and gradually diminish to a point; they are of a sea-green colour, with some white spots; their edges, and also their upper parts below and above, are beset with pretty sharp spines; the flowers grow in loose spikes, the tubulous part being red, and the brim of a light green colour.

The ninth sort is a low plant, seldom rising above eight inches high. The leaves of this are triangular, and turn back at their extremity; they are fleshy and entire, their edges being very slightly sawed. These are curiously veined and spotted, somewhat like the feathers on a partridge's breast, from whence it had the name. The flowers grow in very loose spikes, upon stalks about one foot high, they are of a fine red colour tipped with green. This will live in a good green-house through the winter.

I have raised a variety of this from seeds which I received from the Cape of Good Hope, with broader triangular leaves, which spread much more than those of the former, and are not so beautifully spotted; the flower-stalks also grow much taller.

The tenth sort is also a very low plant, never rising to have stalks; the leaves are broad at their base, but are tapering to a point where they are triangular;

H they

they are beset on their edges, and both surfaces, with soft spines, very closely, from whence this plant had the name of Hedgehog Aloe. The flowers grow in a loose head, on the top of the stalk, which is very thick, but seldom a foot high: they are of a fine red colour below, but of a pale green above. This sort may be preserved through the winter in a good green-house, and placed in the open air in summer.

The eleventh sort grows near a foot high, and is furnished with triangular leaves, from the ground upward; these are of a dark green colour, and are placed in form of a triangle; the flowers grow thinly upon very slender foot-stalks, and are of an herbaceous colour, and their upper part turns backward. This sort requires a moderate warmth in winter, so should be placed in a cool part of the stove.

The twelfth sort grows somewhat like the former, being beset with leaves from the bottom, but these are rounder, and end in sharp points; the flowers grow upon taller stalks, which branch out and grow in long close spikes. There is a variety of this sort which has been raised from seeds, which is much larger, the leaves thicker, and the flowers grow upon taller stalks, but this is only a feminal variety.

This sort may be preserved through the winter in a good green-house, but must have very little water given it during the cold weather.

The thirteenth sort grows with its leaves near the ground, which are about six inches in length, and shaped like a tongue, from whence it had the title of Tongue Aloe. The flowers grow in slender loose spikes, each hanging downward; of a red colour below, and green at the top. This is pretty hardy, so may be kept in a common green-house in winter, and set abroad in summer. There is a variety of this sort, with leaves much more spotted.

The fourteenth sort is of humble growth; the leaves come out on every side without order near the ground, they are thick, triangular at their ends, and closely studded with white protuberances, from whence it was called Pearl Aloe. There is a smaller sort of this which hath been long preserved in the English gardens, but the manner of its flowering being the same, I suspect it to be only a variety. This may be preserved through the winter in a common green-house. It flowers at different seasons of the year.

The fifteenth sort is the true Succotrine Aloe, from whence the best sort of Aloe for use in medicine is produced. This hath long, narrow, succulent leaves, which come out without any order, and form large heads. The stalks grow three or four feet high, and have two, three, and sometimes four of these heads, branching out from it: the lower leaves spread out on every side, but the upper leaves turn inward toward the center; the flowers grow in long spikes, upon stalks about two feet high, each standing on a pretty long foot-stalk; they are of a bright red colour tipped with green: these generally appear in the winter season. This sort may be preserved through the winter in a warm green-house, but the plants so managed will not flower so frequently, as those which have a moderate degree of warmth in winter.

The sixteenth sort resembles the eighth in some particulars, but the leaves are much broader, and spread wide on every side; whereas those of the eighth are ranged only two ways, and are narrow. This flowers but seldom, whereas the sixteenth flowers annually in the spring, and may be kept through the winter in a common green-house.

The seventeenth sort never rises from the ground, but the leaves spread flat on the surface; these are plain, succulent, and triangular toward their end. The borders of the leaves, and also the ridge of the angle on their under side, are closely beset with soft white spines. The flower-stalk rises about a foot high, is very slender, and hath three or four small herbaceous flowers standing at a distance from each other. These are tubulous, and cut into six parts at the brim, which turn backward. This sort is tender, so should be placed in winter in a moderate degree of heat, and

must have little water. It seldom puts out offsets, so is generally increased by planting the leaves.

The eighteenth sort is also a small plant growing near the ground; the leaves of this sort are almost cylindrical toward their base, but angular near their ends, and are set with short soft spines at the angles: these leaves are shorter and of a darker green colour than those of the former sort, and the plants produce many suckers on every side. I have raised a variety of this from seeds, which hath shorter, whiter, and smoother leaves, but this hath not yet flowered. This will live in a common green-house in winter.

The nineteenth sort hath very short, thick, succulent leaves, which are compressed on their upper side like a cushion, from whence it had the name. This grows very close to the ground, and puts out suckers on every side: the flowers grow on slender stalks, and are of an herbaceous colour. This may be preserved through the winter in a good green-house, but should have very little water during that season, especially when it hath no artificial heat.

The twentieth sort hath long narrow tongue-shaped leaves, which are hollowed on their upper side, but keel-shaped below: these are closely studded on every side, with small white protuberances, from whence the plant hath had the title of Pearl Tongue Aloe. The flowers of this kind grow on pretty tall stalks, and form loose spikes, each hanging downward: they are of a beautiful red colour, tipped with green. This sort produces offsets in plenty, and is so hardy as to live in a common green-house through the winter. It flowers at different seasons of the year.

The twenty-first sort hath some resemblance to the last, but the leaves are much broader and thicker; these spread out every way, and are not so concave on their upper surface, nor are the protuberances so large as those of the former; the flowers are of a paler colour, and the spikes are shorter. I have raised plants from the seeds of this sort, which have varied from the original, but none of them approached near the twentieth sort. This is as hardy as the former sort.

The twenty-second sort rises to the height of eight or ten feet, with a strong stem; the leaves grow on the top, which closely embrace the stalk; these come out irregularly, and spread every way; they are near four inches broad at their base, and diminish gradually to the top, where they end in a spine. They are of a dark green colour, and closely beset with short thick spines on every side. This sort hath not as yet flowered in England, nor does it put out suckers, so that it is difficult to increase. It must have a warm green-house in winter, and very little water.

The twenty-third sort hath very long, narrow, triangular leaves, shaped like those of the Bull-rush; the flowers are produced in close thick spikes, upon stalks near three feet high. They are of an Orange colour, having six yellow stamina, which come out beyond the tube of the flower; so that when the plants are strong, and produce large spikes, they make a fine appearance. It flowers in August and September. There is a variety of this with narrower leaves, and longer spikes of flowers.

The soil in which these plants thrive best, is one half fresh light earth from a common (and if the turf is taken with it and rotted, it is much better); the rest should be white sea sand and sifted lime rubbish, of each of these two, a fourth part; mix these together six or eight months at least before it is used, observing to turn it over often in the time.

The middle of July is a very proper season to shift these plants; at which time you may take them out of the pots, and with your fingers open the roots, and shake out as much of the earth as possible, taking off all dead or mouldy roots, but do not wound or break the young fresh ones: then fill the pot about three parts full of the above-mentioned earth, putting a few stones in the bottom of the pot, to drain off the moisture; and after placing the roots of the plant in such a manner as to prevent their interfering too much with each other, put in as much of the same earth, as

A L O

to fill the pot almost to the rim, and observe to shake the plant, so as to let the earth in between the roots; and then with your hand settle it close to the roots of the plant, to keep it steady in the pot; then water them gently, and set them abroad in a shady place, where they may remain for three weeks, giving them gentle waterings, if the weather should prove hot and dry.

Toward the latter end of September, in a dry day, remove them into the house again, observing to give them as much free open air as possible, while the weather is warm; but, if the nights are cool, you must shut up the glasses, and give them air only in the day; and, as the cold increases, you must not open the glasses, but observe to give them gentle waterings often, till the middle of October, when you must abate watering according to the heat of the house in which they are kept. For those plants which are placed in a stove, will require to be watered at least once a week, most part of the winter; whereas those which are kept in a green-house without artificial heat, should not be watered oftener in winter than once a month.

When these hardier sorts of Aloes are placed abroad in summer, they should have but little water given them; and if much rain should fall during the time they are abroad, they should be screened from it: for when they imbibe much wet in summer, they frequently rot the following winter, especially if they are not kept in a moderate warm air. Therefore, those who choose to treat these plants hardily, should be cautious of their receiving too much moisture.

The tender sorts should constantly remain in the stove, or be removed in summer to an airy glass-case, where they may have free air in warm weather, but be protected from rain and cold. With this management the plants will thrive and increase, and such of them as usually flower, may be expected to produce them in beauty at their seasons.

The hardier sorts thrive much better when they are exposed in summer, and secured from the cold and rain in winter, than if they are treated more tenderly. For when they are placed in a stove, they are kept growing all the winter, whereby they are drawn up weak; and although they will flower oftener when they have a moderate share of heat, yet in two or three years, the plants will not appear so slightly as those which are more hardily treated.

The twenty-third sort is hardy enough to live abroad in mild winters, if they are planted in a warm border and a dry soil; but as they are often destroyed in severe winters, it is proper to keep some plants in pots, which may be sheltered in winter under a frame, to preserve the sort. This is propagated by seeds, which the plants generally produce in plenty: the seeds must be sown in pots soon after they are ripe, and in winter should be sheltered under a common hot-bed frame: in the spring the plants will come up, when they should be inured to bear the open air by degrees; and when they are large enough to remove, some of them should be planted in pots, and the other in a warm border, where they will require to be sheltered the following winter, as they will not have obtained sufficient strength to resist the cold.

Most of these Aloes are increased by offsets, which should be taken from the mother plant, at the time when they are shifted, and must be planted in very small pots, filled with the same earth as was directed for the old plants; but if, in taking the suckers off, you observe that part which joined to the mother root to be moist, you must let them lie out of the ground in a shady dry place six or eight days to dry before they are planted, otherwise they are very subject to rot. After planting, let them remain in a shady place (as was before directed in shifting the old plants) for a fortnight, when you should remove the tender kinds to a very moderate hot-bed, plunging the pots therein, which will greatly facilitate their taking new root; but observe to shade the glasses in the middle of the day, and to give them a great share of air.

A L S

Toward the middle of August, begin to harden these young plants, by taking off the glasses in good weather, and by raising them at other times with props, that the air may freely enter the bed, which is absolutely necessary for their growth, and to prepare them to be removed into the house, which must be done toward the end of September, and managed as before directed for the old plants.

The African Aloes, for the most part, afford plenty of suckers, by which they are increased; but those few that do not, may be most of them propagated, by taking off some of the under leaves, laying them to dry for ten days or a fortnight, as was directed for the offsets; then plant them in the same soil as was directed for them, putting that part of the leaf which adhered to the old plant, about an inch, or an inch and a half (according to the size of the leaf) into the earth, giving them a little water to settle the earth about them; then plunge the pots into a moderate hot-bed, observing to screen them from the violence of the sun, and give them gentle refreshings with water once a week: the best season for this is in June, that they may push out heads before winter.

The second sort produces the Aloes commonly sold in the shops for horses, and is called Aloe Hepatica. But it is from the fifteenth sort, the Succotrine, or best sort of Aloes, is produced; which is done by cutting their leaves transversely, and placing earthen vessels under them to receive the juice which drops from these cut leaves; which juice, when inspissated, becomes the Aloe which is used in medicine. But I believe in making the coarser sort of Aloes, they press the leaves, whereby a greater quantity of juice is obtained: but this is not near so fine as the other.

ALOIDES. See STRATIOTES.

ALOPECUROS [Gr. Ἀλοπέκωρ], Fox-tail, a kind of grass.

ALPINIA.

This plant is so called after Prosper Alpinus, who was a famous botanist in his time, and travelled into Greece and Egypt, and has written two books in quarto of the plants of those countries.

The CHARACTERS are,

It hath a trifid empalement, upon which rests the germen. The flower is of one leaf, which is unequally divided at the top into four parts, and resembles a personated flower; the upper segment which resembles the helmet, and also the two side segments, are indented in the middle, and the lower one is divided into three parts at the brim; in the center is placed the round germen, supporting a single style crowned with a three cornered stigma: this is attended by a single stamina fixed to the tube of the flower, which is crowned with a very narrow summit. After the flower is past, the germen becomes an oval fleshy fruit, divided into three parts, inclosing several oval seeds, which have tails.

This genus of plants, is by Dr. Linnæus ranged in his first class, which is entitled Monandria Monogynia, the flowers of which have but one stamina and one style.

We know but one SPECIES of this genus, viz.

ALPINIA. Royen. Prod. 12. This is by father Plumier titled, *Alpina racemosa alba Cannacori foliis.* Nov. Gen. 26. i. e. *White branching Alpina, with leaves like the flowering Reed.*

This plant is a native of the West-Indies, from whence it has been brought into some of the curious gardens of Europe, where it must be preserved in a good green-house, and the pots plunged into a tub of water, otherwise it will not thrive in this country. The leaves decay every winter, and are pushed out from the roots every spring, like the Maranta; so may be propagated by parting of the roots when the leaves decay.

ALSINE [Gr. Ἀλσίνη], Chick-weed.

These plants are so well known to most persons, it will be needless to mention them in this place, unless it be to caution persons from permitting them to grow either in their gardens, or on dunghills, where they will soon shed their seeds, and become troublesome weeds;

weeds; but as they are annual, they may with little trouble be destroyed, if they do not stand to produce seed.

ALTHEA [*ἄλθαία*, so called from *ἀλθαίω*, Gr. to heal], Marshmallow.

The CHARACTERS are,

The flower hath a double empalement; the outer is of one leaf, and is unequally divided into nine narrow segments at the brim; the inner one is also of one leaf, cut into five broad acute segments at the top; these are both permanent. The flower hath five petals which coalesce at their base, but spread open above and are shaped like a heart. There are many stamina joined below, and form a kind of cylinder, but are loose above, and inserted in the column. In the center is placed the orbicular germen, supporting a short cylindrical style, crowned with numerous stigma, which are of equal length with the stamina. The empalement afterward becomes an orbicular depressed capsule, divided into several cells, each containing one compressed kidney-shaped seed.

This genus of plants is ranged by Dr. Linnæus in the third section of his sixteenth class, which is titled Monodelphia Polyandria, the stamina being joined together to form a sort of column.

The SPECIES are,

1. **ALTHEA** foliis simplicibus acuminatis acutè dentatis tomentosis. Marshmallow with single woolly leaves, which are indented in sharp segments. *Althæa Dioscoridis & Plinii*. C. B. P. 315. Common Marshmallow.
2. **ALTHEA** (*Officinalis*) foliis simplicibus angulato-rotundioribus tomentosis. Marshmallow with angular, woolly, round-pointed leaves. *Althæa folio rotundiori aut minus acuminato*. Sutherl. Edinb.
3. **ALTHEA** (*Hirsuta*) foliis trifidis piloso-hispidis supra glabris. Hort. Cliff. 349. Marshmallow with trifid, hairy, pungent leaves. *Alcea villosa*. Dalechamp. Hist. 594.
4. **ALTHEA** (*Cannabina*) foliis inferioribus palmatis superioribus digitatis. Hort. Cliff. 205. Marshmallow with the under leaves shaped like a hand, and the upper leaves more divided. *Alcea fruticoso cannabinio folio*. Clus. Hist. p. 2. pag. 25.

The first sort is the common Marshmallow, which grows naturally in moist places in divers parts of England, and is frequently used in medicine. It hath a perennial root and an annual stalk. The plant grows erect, to the height of four or five feet, and puts out a few lateral branches on the side of the stalks, garnished with leaves which are hoary and soft to the touch; they are angular, and placed alternately on the branches; the flowers come out from the wings of the leaves, which are shaped like those of the Mal-low, but are smaller and of a pale colour. These appear in June or July, and the seeds ripen in September. It may be propagated fast enough, either by seeds or parting their roots. When it is propagated by seeds they should be sown in the spring, but if by parting their roots, the best time is in autumn, when the stalks decay. It will thrive in any soil or situation, but in moist places will grow larger than in dry land. The plants should not be nearer together than two feet, for their roots spread wide on every side.

The second sort is somewhat like the first, but the leaves are not so long, nor do they end in a sharp point, but are angular, and rounder than those of the first. I have cultivated this in the Chelsea garden many years, and find it retains its difference.

The third sort grows naturally in Spain and Portugal; from both these countries I have received the seeds. This is a low plant, whose branches trail on the ground, unless they are supported by stakes. The leaves and stalks are beset with strong hairs; the flowers come out at the wings of the stalks, and are smaller than those of the common sort, having purplish bottoms. The leaves are deeply cut into three parts, and have long foot-stalks; the stalks are woody, but seldom last more than two years.

If the seeds of this sort are sown in April, the plants will flower in July, and the seeds ripen in September.

ber. They should be sown in the places where they are to remain, for as the roots shoot deep into the ground, unless the plants are removed very young, they seldom survive transplanting.

The fourth sort has a woody stem, which rises to the height of four or five feet, and puts out many side branches. These are garnished with leaves of different shapes; those which are on the lower part of the stalks are like a hand, very slightly cut toward their outside; but those which are placed on the upper part of the branches, are deeply cut into several parts; these are hairy, and grow alternately on the branches; the flowers come out from the wings of the stalks in the same manner as the other sorts, but are not so large as those of the common Marshmallow; they are of a deeper red colour, and the empalement is much larger. This sort seldom flowers the first year, unless the summer proves warm; but when the plants live through the winter, they will flower early the following summer, and produce good seeds. This grows naturally in Hungary and Istria, from both which places I have received the seeds.

It is propagated by seeds, which should be sown in the spring in the place where the plants are to remain; or if otherwise, the plants must be transplanted young, else they will not succeed. They should have a sheltered situation and a dry soil, otherwise they will not live through the winter in England. When these plants grow in a stony soil, or in lime rubbish, they will be stunted in their growth, but they will have less sap in their branches, so will better endure the cold of this climate. This sort seldom continues longer than two years in England, but as the seeds ripen here, the plants may be had in plenty.

ALYSSUM, [*ἄλυσσον*, of *ἀλύσσω*, Gr. to be mad; so called, because it was believed to have the virtue of curing madness.] Madwort.

The CHARACTERS are,

The flower hath an oblong four-leaved empalement, which falls away. It hath four petals in form of a cross, which spread open above the empalement. It hath six stamina, two of which are shorter than the other four, crowned with broad summits; in the center of the flower is situated the oval germen, supporting a single style, crowned with an obtuse stigma. After the flower is past, the germen becomes a globular or compressed seed-vessel, in which are lodged several compressed seeds.

This genus is ranged in the fifteenth class of Linnæus, entitled Tetradynamia Siliculosa; the flowers of this class have six stamina, four of which are longer than the other two, and the seed-vessels are short, in some globular, and in others they are compressed.

The SPECIES are,

1. **ALYSSUM** (*Saxatile*) caulibus frutescentibus paniculatis foliis lanceolatis mollissimis undulatis integris. Prod. Leyd. 331. Madwort with shrubby stalks, flowers growing in panicles, and whole, soft, spear-shaped waved leaves. *Alysson Creticum saxatile foliis undulatis incanis*. Tourn. Cor. 15.
2. **ALYSSUM** (*Halimifolium*) foliis lanceolato-linearibus acutis integerrimis caulibus procumbentibus perennantibus. Hort. Cliff. 333. Madwort with whole, spear-shaped, pointed leaves, and trailing perennial stalks. *Alysson halimi folio sempervirens*. Tourn. Inst.
3. **ALYSSUM** (*Spinosum*) ramis floreis senilibus spiniformibus nudis. Hort. Cliff. 332. Madwort, whose older branches have naked spines. *Thlaspi fruticosum spinosum*. C. B. P. 108.
4. **ALYSSUM** (*Montanum*) ramulis suffruticosis diffusis foliis punctato-echinatis. Hort. Upsal. 85. Madwort with shrubby diffused branches and leaves, having prickly punctures. *Thlaspi montanum luteum*. J. B. 2. p. 928.
5. **ALYSSUM**

5. *ALYSSUM (Incanum)* caule erecto foliis lanceolatis incanis integerrimis floribus corymbosis. Hort. Cliff. 332. *Madwort with an erect stalk, hoary spear-shaped leaves which are entire, and flowers collected into round heads.* Alysson fruticosum incanum. Tourn. Inst. R. H.
6. *ALYSSUM (Clypeatum)* caule erecto herbaceo filiculis sessilibus ovalibus compresso-planis petalis acuminatis. Lin. Sp. Plant. 651. *Madwort with an erect herbaceous stalk, pods growing close to the stalks, which are oval and compressed, and the flower leaves pointed.* Lunaria leucoii folio filiquâ oblongâ majori. Tourn. Inst. 218.
7. *ALYSSUM (Sinuatum)* caule herbaceo foliis lanceolatis dentatis filiculis inflatis. Lin. Sp. Plant. 651. *Madwort with an herbaceous stalk, spear-shaped indented leaves, and swollen seed-vessels.* Alysioides incanum foliis sinuatis. Tourn. Inst. 213.
8. *ALYSSUM (Creticum)* caule herbaceo erecto foliis incanis lanceolatis integerrimis filiculis inflatis. Lin. Sp. Plant. 651. *Madwort with an erect herbaceous stalk, hoary, spear-shaped, entire leaves, and a swelling seed-vessel.* Alysioides fruticosum Creticum leucoii folio incano. Tourn. Cor. 15.
9. *ALYSSUM (Vesicaria)* foliis linearibus dentatis, filiculis inflatis angulatis acutis. Lin. Sp. 910. *Madwort with linear indented leaves and swollen pods, which are angular and acute pointed.* Vesicaria Orientalis, foliis dentatis. Tourn. Cor. 49.
10. *ALYSSUM (Deltoidum)* caulibus suffrutescentibus prostratis, foliis lanceolato-deltoidibus, filiculis hirtis. Lin. Sp. 908. *Madwort with trailing shrubby stalks, deltoid spear-shaped leaves, and hairy pods.* Alysson Creticum foliis angulatis, flore violaceo. Tourn. Cor. 15.
11. *ALYSSUM (Calycinum)* caulibus herbaceis, staminibus omnibus dentatis, calycibus persistentibus. Jacq. Vind. 114. *Madwort with herbaceous stalks, all the stamina indented, and a permanent flower-cup.* Thlaspi Alysson dictum campestre majus. C. B. P. 107.
12. *ALYSSUM (Campestre)* caule herbaceo, staminibus stipatis pari setarum, calycibus deciduis. Lin. Sp. 909. *Madwort with an herbaceous stalk, and the flower-cup deciduous.* Alysson incanum, serpylli folio, fructu nudo. Tourn. Inst. 217.

The first sort is a low perennial plant, with a fleshy stalk, which seldom rises more than one foot high, but divides into many leis branches which grow near the ground, so that a single plant will spread to a considerable distance. The branches are garnished with long spear-shaped leaves, which are hoary and waved on their edges, placed on without any order. The flowers are produced in loose panicles, at the extremity of every branch, and are of a bright yellow colour, consisting of four petals, placed in form of a cross: these being numerous, make a fine appearance during their continuance. They appear the latter end of April, or the beginning of May, and if the season is moderate, will continue three weeks in beauty. The seeds ripen in July, but it is only from young plants that seeds can be expected; for the old plants, or those which are raised from slips or cuttings, rarely produce seeds in England.

This plant is hardy, and although brought from a more southerly climate, yet, if planted in a dry, lean, or rubbishy soil, will endure our severest winters abroad. It is increased by sowing the seeds in March in a light sandy soil, or by planting cuttings in April or May; which are very apt to take root, if kept shaded in the heat of the day, and gently refreshed with water.

The second sort seldom continues above two or three years with us, and must therefore be often sown to preserve it; or if the seeds are suffered to fall, and remain upon the ground, the plants will rise without any trouble. This plant spreads itself upon the ground, and never rises to any height. It produces, at the extremity of its branches, very pretty tufts of small white flowers; of which the plant is seldom destitute for six or seven months successively, for which reason it deserves a place in the gardens of the curi-

ous. This will grow from seeds, and also from cuttings, if planted and managed as the former.

The third sort hath ligneous branches which rise about two feet high; these are armed with small spines; the leaves are hoary, spear-shaped, and thinly placed on the stalks without any order. The flowers are white, cross-shaped, and grow in small clusters at the extremity of the branches. After the flowers are past, the germen turns to an oblong seed-vessel, containing several round seeds.

This may be propagated in the same manner as the first sort, either by seeds or slips; and when the plants grow in rubbish, or on old walls, they will last much longer, and endure the cold of our winters better than those which are in a good soil. It grows naturally in Spain, Italy, and the south of France.

The fourth sort hath trailing branches, which lie on the ground; these are garnished with oblong hoary leaves, which are rough to the touch, and are placed alternately on every side of the branches; the flowers are produced in small clusters at the extremity of the branches, which are of a dark yellow colour, and are succeeded by seed-vessels shaped like those of the third sort. This grows naturally upon rocks and ruins, in Burgundy, and some other parts of France, as also about Basil. It may be propagated in the same manner as the former sorts, and when it grows in rubbish, the plants will continue some years; but in rich ground, they seldom live through the winter in England.

The fifth sort grows to the height of two feet, having ligneous stalks, which divide into several branches toward the top. These are garnished with hoary spear-shaped leaves, which are placed alternately on the branches: at the extremity of every shoot, the flowers are produced in round bunches, which are small, white, and cross-shaped; these are succeeded by oval seed-vessels, which are full of brown seeds. It grows naturally in the south of France, Spain, and Italy, chiefly on rocky or gravelly soils. When this is sown in a rich soil, it seldom survives the winter; but in lime rubbish, or upon old walls, it will continue several years. It flowers in June, July, August, and September, and the seeds ripen soon after; which if permitted to scatter, the plants will come up, and require little care.

The sixth sort is a biennial plant with an herbaceous stalk, which is garnished with oblong hoary leaves, placed alternately; the flowers come out from the wings of the stalks single, and are succeeded by oval compressed seed-vessels, shaped like those of the Lunaria, which contain many flat seeds. It grows naturally in Spain and Portugal, from whence I have received the seeds. It is propagated by seeds, which must be sown upon dry ground, or lime rubbish; for in rich land the plants will grow too vigorous in summer, so that in autumn they generally rot off and decay.

The seventh sort is a low spreading plant, which divides into small branches, these spread near the ground, and are garnished with oblong hoary leaves which continue through the year: the flowers are produced in small clusters at the extremity of the branches; they are of a bright yellow colour, consisting of four petals placed in form of a cross. After the flower is past, the germen becomes an oval swelling seed-vessel, which is filled with roundish seeds. This grows naturally in the islands of the Archipelago, but is hardy enough to live in the open air in England, in a dry soil and a warm situation. It is propagated by seeds, and seldom lasts longer than two or three years.

The eighth sort grows more erect, having an herbaceous stalk, which sends out a few lateral branches toward the top, garnished with oblong hoary leaves. The flowers grow in small clusters at the extremity of the branches, which are succeeded by oval swelling seed-vessels like the former. This seldom continues longer than two years in England; it must have a warm dry situation, otherwise it will not live in the open air, and is propagated by seeds, which should

be sown in August, soon after they are ripe; and if a few of them are potted in October, and sheltered under a frame in winter, they will flower the following June, so good seeds may be obtained the same year; for those plants which arise early in the year, grow luxuriantly in summer, so do not often live through the winter, or ripen seeds.

The ninth and tenth sorts have trailing stalks, which spread on the surface of the ground; the plants produce their flowers toward the extremity of the stalks in loose spikes, which are formed like those of the other sorts, having four petals in each in form of a cross; those of the ninth sort are succeeded by swollen seed-vessels; but the tenth, which flowers early in the spring, are rarely succeeded by seed-vessels in this country. This is an abiding plant, which may be propagated from its trailing branches, which, if planted in April, will take root and become good plants by the following autumn, when two or three plants may be placed in a common frame for shelter in winter, to preserve the species; for in hard winters, those which are exposed are sometimes destroyed. The eleventh and twelfth are both annual plants, so are propagated by seeds, which should be sown in a border of light earth in April, in such places where the plants are to remain; if these are thinned and kept clean from weeds, they will flower in July, and perfect their seeds in autumn.

AMARANTHOIDES. See GOMPHRENA.

AMARANTHUS [*Ἀμάραντος*; of *α* privative, and *μαράω*, Gr. to wither; so called, because the flower of this plant being cropped, does not soon wither; but being dried, keeps the beauty of its colour a great while.] Flower-gentle.

The CHARACTERS are,

It hath male and female flowers in the same plant. The flower hath no petals, but the empalement consists of three or five pointed spear-shaped leaves which are coloured and permanent; this is common to both sexes. The male flowers have in some species three, and in others five slender stamina, which are of the same length with the empalement, crowned with oblong summits. The female flowers have an oval germen, supporting three short awl-shaped styles, which are crowned with simple stigma. The empalement afterward becomes an oval coloured seed-vessel having one cell, in which is lodged a single globular seed.

This genus of plants is by Dr. Linnæus ranged in the fifth division of his twenty-first class, entitled Monœcia Pentandria, from their having male and female flowers on the same plant, and the male flowers having five stamina.

The SPECIES are,

1. AMARANTHUS (*Tricolor*) glomerulis triandris axillaribus subrotundis amplexicaulibus foliis lanceolato-ovatis. Lin. Sp. Plant. 1403. *Flower-gentle with roundish heads, placed at the wings of the stalks embracing them, whose flowers have three stamina, and the leaves are oval and spear-shaped.* Amaranthus tricolor. Lob. Icon. 252. i. c. *Three coloured Amaranthus.*
2. AMARANTHUS (*Melancholicus*) glomerulis triandris axillaribus subrotundis sessilibus foliis lanceolatis acuminatis. Lin. Sp. Plant. 1403. *Flower-gentle with three stamina, roundish heads growing close to the stalk, and acute-pointed spear-shaped leaves.* Amaranthus colore obscuriori live mas. Tourn. Inst. 236. Amaranthus bicolor.
3. AMARANTHUS (*Tristis*) glomerulis triandris rotundatis subsPICATIS, foliis ovato-cordatis emarginatis petiolo brevioribus. Lin. Sp. 1404. *Flower-gentle with three stamina, roundish heads growing from the wings of the stalks in spikes, and oval heart-shaped leaves with short foot-stalks.*
4. AMARANTHUS (*Caudatus*) racemis pentandris decompositis cylindricis pendulus longissimis. Hort. Cliff. 443. *Flower-gentle with five stamina, and very long, hanging, cylindrical spikes.* Amaranthus maximus paniculâ longâ pendulâ semine rubello. Raii Hist.
5. AMARANTHUS (*Maximus*) racemis subcylindricis pendulis, caule erecto arboreo. *Flower-gentle with hanging almost cylindrical spikes, and an erect tree-like stalk.*

Amaranthus maximus. C. B. P. 120. *Commonly called Tree-like Amaranthus.*

6. AMARANTHUS (*Lividus*) glomerulis triandris subsPICATIS rotundatis, foliis rotundo-ovatis retusis. Lin. Sp. 1404. *Flower-gentle with roundish spikes of flowers having three stamina, and roundish, oval, blunt leaves.* Blitum pulchrum rectum magnum rubrum. J. B. 2. p. 966.
7. AMARANTHUS (*Flavus*) racemis pentandris compositis, summo infimisque nutantibus, foliis ovatis mucronatis. Lin. Sp. 1406. *Flower-gentle with a compound spike of flowers having five stamina, and oval pointed leaves.*
8. AMARANTHUS (*Blitum*) glomeratis lateralibus trifidis foliis ovatis retusis, caule diffuso. Lin. Sp. Plant. 990. *Flower-gentle with roundish beads at the joints of the stalks, oval blunt leaves, and diffused stalks.* Blitum album minus. C. B. P. 118. *The smaller white Blite.*
9. AMARANTHUS (*Gracizans*) glomerulis triandris axillaribus foliis lanceolatis obtusis. Lin. Sp. Plant. 1405. *Flower-gentle with flowers having three stamina, which grow in clusters from the wings of the stalks, and blunt spear-shaped leaves.* Amaranthus floribus lateralibus congestis foliis lanceolatis obtusis. Flor. Virg. 116. *Commonly called Pellitory-leaved Blite.*
10. AMARANTHUS (*Hybridus*) racemis pentandris decompositis congestis nudis, spiculis conjugatis. Flor. Virg. 148. *Flower-gentle with five stamina, decomposed spikes having double spiculæ.* Amaranthus sylvestris maximus Novæ Angliæ spicis viridibus. Raii Hist. 201. *Or Wild New England Blite with green spikes.*
11. AMARANTHUS (*Hypocondriacus*) racemis pentandris compositis confertis erectis, foliis ovatis mucronatis. Hort. Cliff. 444. *Flower-gentle with five stamina, erect clustered spikes, and oval-pointed leaves.* This is the Amaranthus sylvestris maximus Novæ Angliæ spicis purpureis. Tourn. Inst. R. H. 235. *Commonly called Purple Flower-gentle.*
12. AMARANTHUS (*Spinosus*) racemis pentandris cylindricis erectis axillis spinosis. Hort. Cliff. 444. *Flower-gentle with five stamina, upright cylindrical spikes, and spines at the joints of the stalks.* Amaranthus Indicus spinosus spicâ herbacæâ. H. L. 31.
13. AMARANTHUS (*Sanguineus*) racemis pentandris compositis erectis, lateralibus patentissimis, foliis ovato-oblongis. Lin. Sp. 1407. *Flower-gentle with compound spikes, whose lateral spikes spread out, the upper are erect, and oblong oval leaves.* Amaranthus racemis cylindricis lateralibus terminalibusque cruciatim positus. Fig. Plant. 22.
14. AMARANTHUS (*Retroflexus*) racemis pentandris lateralibus terminalibusque caule flexuoso villoso ramis retrocurvatis. Lin. Sp. Plant. 991. *Flower-gentle with five stamina, spikes proceeding from the wings of the stalks, and also at their extremities, and flexible, hairy, re-curved branches.*
15. AMARANTHUS (*Oleraceus*) glomeribus triandris pentandrisque, foliis ovatis obtusissimis emarginatis rugosis. Lin. Sp. 1403. *Flower-gentle whose globes have flowers with three and five stamina, and rough, obtuse, indented leaves.* Blitum album majus. C. B. P. 118.
16. AMARANTHUS (*Viridis*) glomerulis triandris, floribus masculis trifidis, foliis ovatis emarginatis, caule erecto. Lin. Sp. 1405. *Flower-gentle with globular heads whose flowers have three stamina; the male are trifid, oval, indented leaves, and an upright stalk.*
17. AMARANTHUS (*Cruentus*) racemis pentandris decompositis remotis patulo nutantibus, foliis lanceolato-ovatis. Lin. Sp. Pl. 1406. *Flower-gentle with decomposed spikes of flowers with five stamina, the outer spreading asunder, and oval spear-shaped leaves.* Amaranthus sinensis foliis variis, panicula speciosa patula. Cent. tab. 6.

The first sort has been long cultivated in gardens for the beauty of its variegated leaves, which are of three colours, viz. green, yellow, and red; these are very elegantly mixed: and when the plants are in full vigour, the leaves are large, and closely set from the bottom to the top of the stalks, and the branches form a sort of pyramid; so that there is not a more beau-

beautiful plant than this, when it is in full lustre. From the leaves of this plant being partly coloured like the feathers of parrots, some botanists have separated this species from the others, and constituted a genus of it by the title of *Psittacus*.

The second sort hath been introduced into the English gardens much later than the former. This grows to the same height, and in the manner of its growth greatly resembles it; but the leaves have only two colours, which are an obscure purple, and a bright crimson; these are so blended as to set off each other, and when the plants are vigorous, they make a fine appearance.

The third sort hath no great beauty; it grows about three feet high with an upright stalk, which sends out some lateral branches toward the top; these are garnished with oval heart-shaped leaves. The flowers are produced at the wings of the stalks in roundish spikes, as also at the extremity of the branches, but have very little beauty, so do not deserve a place in the flower-garden. The young plants of this sort are gathered to boil instead of Spinach by the inhabitants of India, where it grows naturally, and from thence I received the seeds of it as an esculent plant.

The fourth sort grows naturally in America. This hath an upright stem, three feet high; the leaves and stalks are of a pale green colour; the spikes of flowers are produced from the wings of the stalks, and also in clusters at the extremity of the branches: they are very long and hang downward, being of a bright purple colour. I have measured some of these spikes, which were two feet and a half long, so that many of them have reached the ground.

The fifth sort hath a strong stem, which rises to the height of seven or eight feet, sending forth many horizontal branches toward the top, garnished with oblong, rough, green leaves. At the extremity of every shoot, the cylindrical spikes of a purple colour are produced, which hang downward; but these are seldom half the length of those of the former sort, and are much thicker. This is the sort of Amaranth, which is directed by the college to be used in medicine.

The sixth sort grows near three feet high, putting out several side branches, which are garnished with oval blunt leaves; at the ends of the branches the spikes are produced in clusters and grow erect, these are of a deep purple colour.

The seventh sort grows near four feet high; the stalks are inclined to red; the leaves are of an oval spear-shaped figure, green colour, marked with purple spots, and have very long foot-stalks. The spikes come out at the extremity of the branches in clusters, as also from the wings of the stalks; these are of a pale green colour, and grow erect. I have received the seeds of this sort from Portugal, by the title of *Bredos*, recommending it to be cultivated as a culinary herb.

The eighth sort grows naturally in most of the warm parts of Europe, and also in America; for wherever it is permitted to scatter its seeds, the plants will come up the following summer, and become troublesome weeds, as will also the ninth sort; so these are seldom cultivated, as they are only preserved in botanic gardens for the sake of variety. The stalks of both these sorts spread on the ground.

The tenth sort grows upward of three feet high, and sends out many side branches, which are hairy, and garnished with oblong rough leaves. The spikes are produced from the wings of the stalks, as also at the extremity of the branches, growing horizontally, and are of a green colour. There is little beauty in this plant, therefore is seldom admitted to gardens, unless for the sake of variety.

The eleventh sort has been long in England, and was formerly propagated in flower-gardens, but is now become a common weed, frequently growing upon dunghills: for as the plants abound with seeds, so where they are permitted to scatter, there will be plenty of the plants come up the following summer.

And these seeds will remain in the ground several years, and as often as they are turned up to the surface, they will produce plants; so that when plants are suffered to stand till their seeds fall, there will be every summer fresh crops of the plants for several years.

The twelfth sort grows about two feet high, putting out many side branches, so as to form a bushy plant; the leaves are oblong, and the spikes come out at every joint, where the stalks are armed with sharp prickles, and at the extremity of the branches, the spikes are longer than those of the side: these are slender, and are inclining to a brown colour, so make no great figure, therefore is rarely allowed to have a place, except in botanic gardens.

The seeds of the thirteenth sort were sent me from the Bahama Islands, as an esculent plant, bearing fine flowers. This grows three feet high, with purple stalks and leaves; the spikes are short and cylindrical; these are frequently produced from the wings of the stalks, but at the extremity of the stalk arises a large cluster of spikes which are placed crosswise, with one upright stalk in the middle. These are of a bright purple colour at first, but afterward fade to a darker colour, as the seeds ripen.

The fourteenth sort is a native of North America, from whence the seeds were sent to Europe, but is now become a common weed in many gardens near London, so is seldom allowed a place, except in botanic gardens.

The fifteenth sort has no beauty, therefore not worthy of a place in gardens: this and the sixteenth sort are esteemed in some parts of India as esculent herbs; the inhabitants of those warm countries, gather the herbs while young, and dress them instead of Spinach, but being much inferior to it, they are seldom used in those countries where Spinach will thrive. These plants grow from two to three feet high, and when they have room, will send out many side branches; but if their seeds are permitted to scatter, there will be a plentiful supply of plants the following summer.

The seeds of the seventeenth sort were brought from China, and the two first years they were sown in England, produced beautiful heads of flowers, which made a gay appearance; but afterward the seeds degenerated, and the plants which were produced from them had little beauty; which is the case with some others of this genus, so should not be esteemed as distinct species.

The sorts which are worthy of a place in the pleasure-garden, are particularly the first and second: these are tender, and require some art and care to bring them to perfection in England, therefore their management will be hereafter more particularly inserted.

Next to these are the fourth, fifth, and thirteenth sorts. The seeds of these should be sown upon a moderate hot-bed toward the end of March, and when the plants come up, they should have a large share of air admitted to them in mild weather, to prevent their drawing up weak. When they are large enough to transplant, there should be another moderate hot-bed provided, to which they should be removed, placing them at six inches distance every way, observing to water them, as also to shade them from the sun until they have taken new root; after which the air should be freely admitted to them, at all times when the weather is favourable; their waterings should be frequent, but not given in great quantities. As the plants advance, and the warmth of the season increases, they should have a greater share of air, that by degrees they may be hardened to bear the open air. The beginning of June they may be taken up with large balls of earth to their roots, and planted some into pots, and others into the borders of the pleasure-garden, observing to shade them until they have taken good root; after which they must be frequently watered in dry weather, especially those in the pots, which will require watering every evening in

in warm dry weather. The fifth sort will not thrive in pots, so should be planted in a rich light soil, where, if it is allowed room, and plentifully watered in dry weather, the plants will grow to a very large size, and make a fine appearance.

The twelfth sort is also tender, so whoever is inclinable to cultivate that plant, should treat it in the same manner as is directed for the former.

The other sorts are hardy enough to grow in the open air, so may be sown on a bed of light earth in the spring, and when the plants are fit to remove, they may be transplanted into any part of the garden, where they will thrive, and produce plenty of seeds, which, if permitted to scatter, will stock the garden with plants.

The two first sorts must be sown on a good hot-bed in February, or the beginning of March at farthest; and in about a fortnight's time, if the bed is in good temper, the plants will rise; soon after which you must prepare another hot-bed, covered with good, rich, light earth, about four inches thick; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into your new hot-bed about four inches distance every way, giving them a gentle watering to settle the earth to their roots; but in doing this, be very cautious not to bear the young plants down to the ground by hasty watering, which rarely rise again, or at least so as to recover their former strength in a long time, but very often rot in the stems, and die quite away.

In the middle of the day keep them screened with mats from the heat of the sun, and give them air by raising up the glasses; and if the glasses are wet, it will be proper to turn them every day, in good weather, that they may dry; for the moisture which is occasioned by the fermentation of the dung, and the perspiration of the plants, is of a noxious quality, and very unkindly to plants; so that if the weather happens to prove bad, that you cannot turn your glasses, it will be of great service to the plants to wipe off all moisture two or three times a day with a woollen cloth to prevent its dropping upon the plants. When the plants are firmly rooted, and begin to grow, you must observe to give them air every day, more or less, as the weather is cold or hot, to prevent their drawing up too fast, which greatly weakens their stems.

In about three weeks or a month's time, these plants will have grown so as to meet, and will stand in need of another hot-bed, which should be of a moderate temper, and covered with the same rich earth about six inches thick, in which they should be removed, observing to take them up with as much earth about their roots as possible, and plant them six or seven inches distance every way, giving them some water to settle the earth about their roots; but be very careful not to water them heavily, so as to bear down the plants, as was before directed; and keep them shaded in the heat of the day, until they have taken fresh roots; and be sure to refresh them often gently with water, and give them air in proportion to the heat of the weather, covering the glasses with mats every night, lest the cold chill your beds, and stop the growth of the plants.

The middle of May you must provide another hot-bed, which should be covered with a deep frame, that the plants may have room to grow. Upon this hot-bed you must set as many three-penny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams: when the bed is in good order to receive the plants, they should be carefully taken up with a trowel, or some such instrument, observing to preserve as much earth to their roots as possible; then place each single plant in the middle of one of the pots, filling the pot up with the earth before described, and settle it close to the root of the plant with your hands; water them gently, as before, and shade them in the heat of the

day from the violence of the sun, by covering the glasses with mats.

In about three weeks more these plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is soft, and the sun is clouded, draw off the glasses, and expose them to the open air; and repeat this as often as the weather will permit, which will harden them by degrees to be removed abroad into the places where they are to remain the whole season; but it is not advisable to set these plants in the open air till after the first week in July, observing to do it when the air is perfectly soft, and, if possible, in a gentle shower of rain.

Let them at first be set in shelter for two or three days, where they may be screened from the violence of the sun, and strong winds, to which they must be inured by degrees. These plants, when grown to a good stature, perspire very freely, and must be every day refreshed with water, if the weather proves hot and dry; otherwise they will flint, and never produce so large leaves, as those which are skilfully treated.

This is the proper management, in order to have fine *Amaranthus*, which, if rightly followed, and the kinds are good, in a favourable season, will produce large fine leaves, and are the greatest ornament to a good garden for upwards of two months in the latter part of summer.

Where persons are curious in having these annual plants in great perfection, there should be a glass-case erected with upright and sloping glasses on every side, with a pit in the bottom for tan, in which the pots should be plunged; if this is raised eight or nine feet to the ridge, and the upright glasses are five feet, there will be room and height enough to raise these and other annual plants to great perfection, and in such a building, many of those tender annual plants, which rarely perfect seeds in this climate without such contrivance, may be every year brought so forward as to ripen their seeds.

AMARANTHUS CRISTATUS. See *CELOSIA*.

AMARYLLIS, Lily Daffodil.

The CHARACTERS are,

It hath an oblong compressed spathe, (or sheath) which incloses the flower-buds, and open side ways, becomes dry, and is permanent; the flower hath six spear-shaped petals. In the center is situated the roundish furrowed germen, supporting a slender style, crowned with a three-cornered stigma; this is attended by six awl-shaped stamina, which are crowned with incumbent summits. After the flower is past, the germen becomes an oval capsule, opening in three parts, having three cells, which contain round seeds.

This genus is ranged by Dr. Linnæus in the first section of his sixth class of plants, entitled Hexandria Monogynia, from the flower having six stamina and one style.

The SPECIES are,

1. **AMARYLLIS** (*Lutea*) *spatha uniflora, corolla æquali, staminibus declinatis.* Lin. Sp. 420. *Lily Daffodil with a single flower in each spathe, which is equal, and the stamina declined.* Lilio *Narcissus luteus autumnalis major.* Tourn. Inst. 386. Commonly called *autumnal Narcissus.*
2. **AMARYLLIS** (*Atamasco*) *spatha uniflora, corolla æquali, pistillo declinato.* Hort. Cliff. 135. *Lily Daffodil with a single flower in each sheath, which has equal petals, and the pointal declining.* Lilio *Narcissus Indicus pumilus monanthos albus.* Mor. Hist. 2. 266. Commonly called *Atamasco Lily.*
3. **AMARYLLIS** (*Formosissima*) *spatha uniflora, corolla inæquali, petalis tribus genitalibusque declinatis.* Hort. Cliff. 135. *Lily Daffodil with one flower in each cover, which has unequal petals, and the stamina and style are declined.* Lilio *Narcissus Jacobæus flore sanguineo nutante.* Hort. Elth. 195. Commonly called *Jacobæa Lily.*
4. **AMARYLLIS** (*Sarniensis*) *spatha multiflora, corollis revolutis genitalibus.* Hort. Upsal. 75. *Lily Daffodil with*

with many flowers in one cover; the petals equal, spread open, and turned backward, with broken stamina, commonly called *Guernsey Lily*.

5. AMARYLLIS (*Regina*) spathâ multiflorâ, corollis campanulatis æqualibus, genitalibus declinatis. Hort. Cliff. 135. *Lily Daffodil with many flowers in one cover, the petals equal and bell-shaped, and the stamina declined.* Lilio Narcissus polyanthos flore incarnato, fundo ex luteo albescente. Sloan. Cat. Jam. 115. commonly called *Belladonna Lily*.
6. AMARYLLIS (*Belladonna*) spathâ multiflorâ corollis campanulatis marginibus reflexis genitalibus declinatis. *Lily Daffodil with many flowers in one cover, the petals equal and bell-shaped, their borders turning backward, and declining stamina.* Liliun Americanum puniceo flore, Belladonna dictum. Par. Bat. 194. commonly called *Mexican Lily*.
7. AMARYLLIS (*Longifolia*) spathâ multiflorâ, corollis campanulatis æqualibus, scapo compresso longitudini umbellæ. Flor. Leyd. 36. *Lily Daffodil with many flowers in one cover, the petals equal, and the cover compressed the length of the umbel.* Liliun Africanum humile longissimis foliis polyanthos saturato colore purpurescens. Par. Bat. 195.
8. AMARYLLIS (*Zeylanica*) spathâ multiflorâ corollis campanulatis æqualibus, genitalibus declinatis scapo tereti ancipiti. Flor. Leyd. 36. *Lily Daffodil with many flowers in one cover, the petals equal, and the cover opening two ways.* Lilio Narcissus Zeylanicus latifolius flore niveo externè lineâ purpureâ striato. Hort. Amst. 1. 73. commonly called *the Ceylon Lily*.
9. AMARYLLIS (*Ciliaris*) spathâ multiflorâ, foliis ciliatis. Flor. Leyd. 37. *Lily Daffodil with many flowers in one cover, and the edges of the leaves hairy.* Lilio Narcissus sphæricus Æthiopicus foliis guttatis & ciliis instar pilosis. Pluk. Alm. 220. commonly called *the African Scarlet Lily*.
10. AMARYLLIS (*Vernalis*) spathâ uniflorâ, corollâ æquali, staminibus erectis. *Lily Daffodil with one flower in a cover, with equal petals, and erect stamina.* Lilio Narcissus luteus vernus. Tourn. Inst. 386. commonly called *Spring yellow Lily Narcissus*.
11. AMARYLLIS (*Orientalis*) spathâ multiflorâ corollis inæqualibus foliis linguiformibus. Buttn. *Lily Daffodil with many flowers in a cover, whose petals are unequal, and leaves shaped like a tongue.* Lilio Narcissus Indicus maximus sphæricus floribus plurimis rubris liliaceis. Mor. Hist. 2. 268. *Brunswickia of Dr. Heister*.
12. AMARYLLIS (*Capensis*) spathâ triflorâ corollis campanulatis æqualibus genitalibus declinatis. *Lily Daffodil with three flowers in each cover, whose petals are equal and bell-shaped, with declining stamina.*
The first sort is very hardy, and increases very fast by offsets. The season for transplanting these roots is any time from May to the end of July, when their leaves are decayed, after which it will be too late to remove them; for they will begin to push out new fibres by the middle of August, or sooner if the season be moist, and many times they flower the beginning of September; so that if they are transplanted, it will spoil their flowering. This plant will grow in any soil or situation; but it will thrive best in a fresh, light, dry soil, and in an open situation; i. e. not under the dripping of trees, nor too near walls. It is commonly called by the gardeners, the Yellow Autumnal Narcissus, &c. and is usually sold by them with Colchicums, for autumnal ornaments to gardens; for which purpose this is a pretty plant, as it will frequently keep flowering from the beginning of September to the middle of November, provided the frost is not so severe as to destroy the flowers; for although there is but one flower in each cover, yet there is a succession of flowers from the same root, especially when they are suffered to remain three or four years unremoved. The flowers seldom rise above three or four inches high; they are shaped somewhat like the flowers of the large yellow Crocus; the green leaves come up at the same time, like the Saffron, and after the flowers are past, the leaves increase all the winter. The roots are bulbous, and shaped like those

of the Narcissus, so are proper ornaments for such borders as are planted with Cyclamens, Saffron, Autumnal Crocus, Colchicums, and such low autumnal flowers.

The tenth sort is more rare in England than any of the other, at present. It was formerly in several curious gardens, but as it flowers at a season when there are so many finer sorts in beauty, it was neglected and cast out of the gardens, whereby it is almost lost in England: it grows naturally in Spain and Portugal, where it flowers early in January. This is as hardy as the first sort, and may be planted in the open borders, and treated in the same manner, excepting that this will not lose its leaves so soon, so should not be taken out of the ground to transplant, till the end of July, or beginning of August. It flowers in April or the beginning of May, but is not of long duration.

The second sort is a native of Virginia and Carolina, in which countries it grows very plentifully in the fields and woods, where it makes a beautiful appearance when it is in flower. The flowers of this sort are produced single, and at their first appearance have a fine Carnation colour on their outside; but fades away to a pale, or almost white, before the flowers decay. This plant is so hardy, as to thrive in the open air in England, provided the roots are planted in a warm situation, and on a dry soil; it may be propagated by offsets from the roots. The flowers of this sort are almost as large as those of the small Orange Lily, but do not grow above six or eight inches high; they appear the latter end of May, or beginning of June, and sometimes it flowers in August in this country.

The third sort, which is commonly called *Jacobæa Lily*, is now become pretty common in the curious gardens in England, the roots sending forth plenty of offsets, especially when they are kept in a moderate warmth in winter: for the roots of this kind will live in a good green-house, or may be preserved through the winter under a common hot-bed frame; but then they will not flower so often, nor send out so many offsets, as when they are placed in a moderate stove in winter. This will produce its flowers two or three times in a year, and is not regular to any season; but from March to the beginning of September, the flowers will be produced when the roots are in vigour. The stems of these flowers are produced from the sides of the bulbs, so that after the flowers produced on one side are decayed, there is another stalk arises from the other side of the bulb; but there is no more than one flower produced on the same stalk. The flowers are large, and of a very deep red; the under petals, or flower-leaves, are very large, and the whole flower stands nodding on one side of the stalk, making a beautiful appearance.

It is propagated by offsets, which may be taken off every year; the best time to shift and part these roots is in August, that they may take good root before winter; in doing of this, there should be care taken not to break off the fibres from their roots. They should be planted in pots of a middling size, filled with light kitchen-garden earth; and if they are kept in a moderate degree of warmth, they will produce their flowers in plenty, and the roots will make great increase.

The sixth sort, which is commonly called the *Mexican Lily*, is not so hardy as the former sort, so must be placed in a warm stove; and if the pots are plunged into a hot-bed of tanners bark, the roots will thrive better, and the flowers will be strong. This is increased by offsets, as the others of this tribe; and flowers usually the beginning of spring, when it makes a fine appearance in the stove: the flower-stems of this sort, seldom rise more than one foot high, each stem supports two, three, or four flowers, rarely more than that number. The flowers are large, and of a bright copper colour, inclining to red; the spatha, or sheath, which covers the buds before they open, divides into two parts to the bottom, standing on each side the umbel of flowers, joined to the small foot-stalks,

The eighth sort is also tender, and must be treated in the same manner as the sixth; this is more common in the gardens in Holland than in this country, and as it is a plant which increases but slowly, will not be very common here. This flowers usually in June and July, and sometimes the same root will flower again in autumn; for if the pots are plunged into a bed of tanners bark, the roots generally flower twice every year, but the flowers are not of long duration. This grows naturally in the West-Indies, from whence I have received roots and seeds.

The seventh and ninth sorts are more hardy, and may be treated in the same manner as the Jacobæa Lily; these will increase pretty fast by offsets, when they are properly managed, especially the ninth, which sends out many offsets, so as to fill the pots with roots, but it seldom flowers in England. The leaves of this are long and narrow, not much unlike those of the Snowdrop. The petals of the flower turn back like those of the Guernsey Lily, but are of a lighter colour, rather inclining to scarlet; the roots of this are small. The seventh sort usually flowers in winter, if the pots are placed in a moderate stove; and as at that season there are few flowers in the open air, these are more valuable on that account.

I received roots of both these sorts from the Cape of Good Hope, which have succeeded in the Chelsea garden. The seventh sort produces a great number of flowers in each umbel, which are of a deep purple colour, but the stalk which supports them, rarely rises more than three or four inches high; these flowers appear in December. The roots of this sort are very large, and the leaves are long, but narrow.

The eleventh sort is figured by Ferrarius in his Garden of Flowers, as also by Morrison in his History of Plants; but Dr. Heister has separated this from the genus, and has constituted a new genus by the title of *Brunswigia*, in honour to the duke of Brunswic. But although the shape of the flowers in this plant are different from most of the others of this genus, yet as there is a uniformity in the characteristic notes of the genus, it should not be separated; for the Jacobæa Lily differs in the form of its flowers, from the other species, full as much as this, therefore might for the same reason be separated from this genus.

This grows naturally at the Cape of Good Hope, from whence I have received the roots, which have succeeded in the Chelsea garden. The bulbs of this sort are large and almost round, the leaves are long, broad, and rounded at their extremities; these spread two ways on the surface of the ground; and do not come up till after the flower-stem appears, which is generally in November; and after the flowers are past, the leaves increase till spring, and in May they begin to decay, so that from the middle of June to October, the roots are entirely naked of leaves.

The twelfth sort is also a native of Africa, I received the roots of this from the Cape of Good Hope with the former. This produces its flowers in February and March. The stems of this rise near two feet high, and have commonly but three flowers inclosed in each sheath, or cover. The flowers are as large as those of the Belladonna Lily, and are of the same form, growing erect, but of a deeper red colour; the leaves are long and narrow, and have a hollow furrow on their upper side, where there is a pale stripe running the length of the leaves, and are very like those of the American *Pancratium*. These leaves decay in summer, about the same time as those of the former, and appear again at the same season.

Both these sorts may be treated in the same manner, as hath been directed for the Jacobæa Lily, with this difference only, of placing these in winter in a stove, where there is a moderate share of warmth, for the roots of these will not endure so much cold as those, nor should they have so much water given them.

The best time to transplant these roots is about the beginning of August, when their leaves are quite decayed, before they put out new fibres, for it will be very improper to remove them afterwards.

All these bulbous-rooted flowers delight in a loose sandy earth, mixed with good kitchen-garden mould; and in the culture of them there should be but little water given them at those times when their leaves decay, and the roots are not in a growing state, for much moisture at that time will often cause them to rot; but when they are growing, and putting out their flower-stems, they should be frequently refreshed with water, but not given in too great quantities at a time. The pots, with the tender sorts, should constantly be kept in the stove; and in summer they should have as much free air as possible; for although some of these sorts may be kept abroad in summer, yet those do not thrive so well, nor flower so constantly, as those which are treated in the manner here described.

The fifth sort, which is called the Belladonna Lily, was brought to England from Portugal, where the gardens some years ago abounded with these flowers; for the roots increase very fast, especially in such countries where they live in the open air. The gardens in Italy have also great quantities of these flowers, especially about Florence; where, at the season of their flowering, they are commonly sold in the markets to adorn their rooms; the Italians call it *Narcissus Belladonna*. This plant thrives so well in Italy, as to need no other culture than the common Lily; and although it does not flower until August, yet it commonly produces good seeds in that country, from which they propagate them in great plenty; but with us they require more care, otherwise they cannot be preserved. The roots of this sort were generally planted in pots, and placed under a hot-bed frame, to screen them from the frost in winter; for as their green leaves come out in autumn, and continue growing all the winter, so when they are exposed to the frost, whereby their leaves are killed, the roots will be in danger of perishing; but if they should survive, they will be greatly weakened by it. With this culture the roots were preserved, but they did not constantly flower, nor put out many offsets, so that few gardens were furnished with this plant; and of late years the roots have been scarce in Portugal, for the Jacobæa Lily having been introduced into that country, has supplanted the other, in most of their gardens, so that the roots which have been brought from thence of late years for the Belladonna Lily, have proved the Jacobæa Lily.

The method in which I have cultivated this plant for some years past, with great success, is as follows. I prepared a border close to a south-west aspect wall, of about six feet wide, in the following manner, viz. I removed all the earth to the depth of three feet, then I put some very rotten dung in the bottom, six inches thick, upon which I laid light garden mould about twenty inches deep; after making this level, I placed the roots at six inches distance every way, and then covered them over with light sandy earth, to the height of the border, whereby the upper part of the roots were five or six inches buried, and in the winter I covered the border all over with rotten tanners bark, three inches deep, to prevent the frost from penetrating the ground; and when the frost was very severe, I laid some mats or straw over the leaves to protect them from being killed. With this management the roots have greatly increased, and have constantly flowered every year; some of them have put out two or three stems, which grew near three feet high, and produced many flowers in each umbel, which have made a fine appearance during the month of October. The green leaves come up soon after, and abide all the winter and spring until June, at which time they decay; soon after which the roots should be transplanted, for if they are let stand till July, they will have sent forth new fibres, when it will greatly injure the roots, if they are disturbed. If some of these roots are planted in a warm border, close to a south wall, and on a dry soil, they will thrive very well, especially if they are covered in severe frost; and these roots will flower much stronger than

than those which are kept in pots; and will multiply faster.

The fourth sort is supposed to come originally from Japan, but has been many years cultivated in the gardens of Guernsey and Jersey; in both which places, they seem to thrive as well as if it was their native country; and from those islands their roots are sent annually to the curious in most parts of Europe, and are commonly called Guernsey Lilies. The roots of this plant are generally brought over in June and July; but the sooner they are taken out of the ground after their leaves decay, they are the better: for although the roots which are taken up when their flower-stems begin to appear, will flower, yet their flowers will not be so large, nor will their roots be near so good after, as those which were removed before they had sent out fresh fibres.

When these roots come over, they should be planted in pots filled with fresh, light, sandy earth, mixed with a little very rotten dung, and placed in a warm situation, observing now and then to refresh the earth with water: but by no means let them have too much wet, which would rot their roots, especially before they come up. About the middle of September, such of the roots as are strong enough to flower, will begin to shew the bud of their flower-stem (which is commonly of a red colour); therefore you should remove these pots into a situation where they may have the full benefit of the sun, and may be sheltered from strong winds: but by no means place them too near a wall, nor under glasses, which would draw them up weak, and render them less beautiful. At this season they should be gently refreshed with water, if the weather be warm and dry; but if it should prove very wet, they should be screened from it.

When the flowers begin to open, the pots should be removed under shelter, to prevent the flowers from being injured by too much wet: but they must not be kept too close, nor placed in a situation too warm, which would occasion their colour to be less lively, and hasten their decay. The flowers of this plant will continue in beauty (if rightly managed) a full month; and though they have no scent, yet, for the richness of their colour, they are justly esteemed in the first rank of the flowery tribe.

After the flowers are decayed, the green leaves will begin to shoot forth in length, and if sheltered from severe cold, will continue growing all the winter; but they must have as much free air as possible in mild weather, and covered only in great rains or frosts; for which purpose, a common hot-bed frame is the properest shelter for them; under which if they are placed, the glasses may be taken off constantly every day in dry open weather, which will encourage the leaves to grow strong and broad; whereas when they are placed in a green-house, or not exposed to the open air, they will grow long and slender, and have a pale weak aspect, whereby the roots will become weak, so that it seldom happens that they produce flowers under such management.

These roots should be transplanted every fourth or fifth year toward the latter end of June, or beginning of July, and planted into fresh earth (but they should not be oftener removed, for that would retard their flowering.) The offsets should also be taken off, and planted into several pots, which, in three years time, will produce flowers; so that after a person is once stocked with these roots, they may increase them, so as to have a supply of blowing roots, without being at the trouble or expence of sending to Guernsey every year for fresh roots; and the roots preserved here will flower stronger than those which are usually brought from thence, for the inhabitants of those islands are not very curious in cultivating them. Their usual method is to plant them at a great distance in a bed of common earth, where they let them remain for many years: in which time they produce such a number of offsets, that many times one single cluster has contained above a hundred roots; by which means, those which grow on the inside are so much compressed

by the outer roots, that they are perfectly flattened; and from the number of roots growing in each cluster, they are all rendered weak, and unfit to produce such large stems of flowers, as those which have grown single, and are of a spherical figure.

But when a person is possessed of a large number of these roots, it will be troublesome to preserve them in pots; therefore there should be a bed prepared of the following earth, in some well sheltered part of the garden, viz. Take a third part of fresh virgin earth from a pasture ground, which is light, then put near an equal part of sea sand, to which you should add rotten dung, and sifted lime rubbish, of each an equal quantity. With this earth (when well mixed and incorporated) you should make your bed about two feet thick, raising it about four or five inches above the surface of the ground, if the situation be dry; but if the ground be wet, it should be raised eight or nine inches higher. In this bed, about the beginning of July (as was before directed), you should plant the roots about six or eight inches asunder each way; and in the winter, when the frost begins, you should either cover the bed with a frame, or arch it over, and cover it with mats and straw, to prevent their leaves from being pinched with cold; but in the spring the covering may be entirely removed, and the bed kept constantly clear from weeds, during the summer, observing to stir the surface of the earth now and then; and every year, when the leaves are decayed, you should shift a little fresh earth over the beds, to encourage the roots. In this bed the roots may remain until they are strong enough to produce flowers, when they may be taken up and planted in pots, as was before directed, or suffered to remain in the same bed to flower.

The roots of these plants do not flower again the succeeding year (as in many other sorts of bulbs;) but if their bulbs contain two buds in their center, as is often the case, they very often flower twice within the compass of three years; after which, the same individual root does not flower again in several years, but only the offsets from it.

AMBROSIA [so called from a privative and *Sporda* mortal,] because feigned by the poets to be the food of the gods.

The CHARACTERS are,

It hath male and female flowers on the same plant. The male flowers are composed of many florets, which are included in one common empalement of one leaf, which is plain, and extended the length of the florets: each floret is of one leaf, funnel-shaped, and cut into five parts at the brim; in the center is situated the five small stamina, which are crowned with pointed crest summits. The female florets are placed under the male in the same spike; these have an empalement of one leaf, which is pointed and permanent: they have no petals, but an oval germen placed in the bottom of the empalement, supporting a slender style, crowned with two long hairy stigma. The germen afterward becomes an oval hard capsule with one cell, crowned with the acute segments of the empalement, and inclosing one roundish seed.

This genus of plants, is by Dr. Linnæus ranged in the fifth division of his twenty-first class, entitled Monœcia Pentandria, from their having male and female flowers in the same plant, and the male flowers having five stamina.

The SPECIES are;

1. AMBROSIA (*Maritima*) foliis multifidis racemis solitariis pilosis. Lin. Sp. Plant. 988. *Ambrosia with leaves divided into many parts, and single hairy spikes of flowers. Ambrosia maritima. C. B. P. Sea Ambrosia.*
2. AMBROSIA (*Elatior*) foliis bipinnatifidis, racemis paniculatis terminalibus glabris. Hort. Upsal. 284. *Ambrosia with double winged leaves, a smooth loose spike of flowers growing at the extremity of the branches. Ambrosia maritima foliis artemisiæ inodori elatior. H. L. 32.*
3. AMBROSIA (*Trifida*) foliis trilobis & quinquelobis serratis. Lin. Sp. 988. *Ambrosia with leaves having three and five lobes,*

- lobes, which are sawed on their edges.* Ambrosia Virginiana maxima, platani orientalis folio. Mor. Hist. 3. p. 4.
4. AMBROSIA (*Artemisifolia*) foliis bipinnatifidis primoribus ramulorum indivisis integerrimis. Lin. Sp. Plant. 988. *Ambrosia with double winged leaves, and the younger branches having entire leaves.* Ambrosia maxima inodora marrubii aquatici foliis tenuiter lacinatis Virginiana. Pluk. Alm. 27. tab. 10.
5. AMBROSIA (*Arborescens*) foliis pinnatifidis hirsutis racemis solitariis terminalibus, caule fruticoso perenne. *Ambrosia with hairy winged leaves, single spikes of flowers growing at the extremity of the branches, and a shrubby perennial stalk.*

The first sort grows naturally in Cappadocia, &c. near the sea shore; this rises about two feet and a half high, sending out branches, garnished with leaves divided into many parts, and upon being handled emit a strong odour. The spikes of flowers are produced from the wings of the stalks, which are long, single, and hairy; the upper part being furnished with many male flowers, and the lower part with female flowers; these grow close to the stalk. After the flowers are past, the female flowers are succeeded by hard leafy capsules having one cell, in which is included a single round seed. This is an annual plant, which seldom perfects its seeds in England, unless the plants are brought forward in the spring; therefore the seeds should be sown in the autumn in a warm border, and when the plants come up in the spring, they should be transplanted into another warm border of poor ground; for when these plants are put into rich moist land, they grow very luxuriantly, so do not flower till late in the season. Therefore the best method to obtain good seeds, is to plant some of the plants in lime rubbish, to prevent their luxuriant growth, which will cause them to flower early, whereby good seeds may be obtained.

If the seeds ripen and are permitted to scatter, the plants will come up the following spring without care; for when the seeds are sown in the spring, the plants seldom come up the same year, but will remain in the ground a year before they vegetate. There is not much beauty in this plant, so it is not often admitted to have a place in gardens, except in those where a variety of plants are preserved.

The second sort grows naturally in the islands of America, as also in Carolina and Virginia; from the two latter countries I have frequently received the seeds, and in the tubs of earth which came with plants from the former, the plants have come up in plenty, so is undoubtedly a common weed there. This grows more than three feet high, dividing into many branches; garnished with winged leaves in shape like those of Mugwort; at the extremity of each branch, the loose spikes of flowers are produced, composed of one long spike in the middle, and three or four shorter lateral spikes: these are smooth, and have male and female flowers ranged in the same manner as the former; the female flowers are succeeded by seeds of the same shape.

This sort will come up and thrive in the open air in England, but the plants so raised will not produce good seeds, unless the season is warm; therefore to obtain them every year, it is necessary to cultivate them in the following manner.

The seeds of this plant should be sown on a moderate hot-bed in March, and when the plants are come up two inches high, they must be transplanted into another moderate hot-bed, allowing each plant three or four inches square; observing to water them pretty well, and shade them until they have taken new root; afterward they must have a large share of fresh air every day, when the weather is warm, and frequent waterings, for they are very thirsty plants. When the plants are grown pretty strong, they must be taken up with balls of earth to their roots, and planted in large pots filled with light earth; and if they are placed on a very moderate hot-bed until they are well rooted, it will greatly forward their flowering. Toward the latter end of May they should be placed abroad

with other hardy annual plants, among which they will make a variety. These will flower in July, and their seeds ripen in September.

The third sort is a native of North America, where it is a very common weed. This often grows eight or ten feet high; and if it is planted in a rich moist soil, or is often watered, it will grow much higher, and spread out into many branches. The seeds of this plant, when sown in the spring, seldom come up the first year, but frequently remain in the ground until the following spring; so that when the plants do not come up, the ground must not be disturbed till after the spring following. When the plants come up, some of them may be transplanted into a moist rich soil, allowing them at least four or five feet room every way; if they are frequently watered in dry weather, they will grow to a large size; but their branches must be supported by stakes, otherwise they are very subject to break with strong winds. The flowers of this plant are not more conspicuous than those of the Hemp, to which these are near akin; therefore are only preserved by such persons as are curious in botany, for the sake of variety. If the seeds of this sort ripen and are suffered to scatter, the plants will come up the following spring, provided the ground is not disturbed; or if the seeds are sown in autumn, the plants will come up the following spring, and may be treated as above.

The fourth sort grows naturally in North America, from whence I have frequently received the seeds. This divides into many branches, the lower part of which are garnished with whole leaves, but the upper part hath compound leaves resembling those of the second sort; the spikes of flowers are produced from the wings of the stalks, in which this differs from the second. This may be treated in the same manner as the second sort.

The fifth sort is a native of Peru, from whence the younger Jussieu sent the seeds to the royal garden at Paris, and by the generosity of his brother Dr. Bernard de Jussieu, I was favoured with this plant, which has succeeded in the Chelsea garden, where it annually perfects its seeds.

This grows to the height of ten or twelve feet, with a woody stem, dividing into several branches, garnished with hairy leaves, composed of several winged lobes, and are placed alternately upon the branches; the spikes of flowers are single, hairy, and are produced at the extremity of the branches. The female flowers (which are situated below the male, on the same spikes) grow in small clusters, at separate distances, each having two long narrow segments of the empalement, which rise above the capsule or seed vessel.

This is a perennial plant, and may be propagated by cuttings or seeds; if by the former, they should be planted in a shady border, in either of the summer months; these will require to be frequently watered: in a month or five weeks they will have good roots, therefore should then be taken up and potted; for when they are left longer in the full ground, they will grow very luxuriant, and not so soon recover their removal, as those which are transplanted earlier. These plants are hardy, so may be exposed to the open air in summer; and in the winter, if they are sheltered in a common green-house, with Myrtles and other hardy exotic plants, they will live several years. In mild winters, the roots of this plant have lived in the full ground in a warm border, without any covering, but hard frost will kill them.

The seeds of this sort seldom come up the same year, when they are sown in spring, but those which have fallen in the autumn, have grown the following year, and so have those which have been sown at the same season.

AMELANCHIER. See CHIONANTHUS.

AMELLUS, Star-flower.

The CHARACTERS are,

The common flower-cup is round and scaly; the flower is of the compound radiated kind; the hermaphrodite flowers compose

compose the disk, and the female the rays: the hermaphrodite are tubulous, with five segments; the female are tongue-shaped, divided into two or three segments; the first have five short stamina, an oval germen with a slender style, and two stigmas; the female are like them. The flower-cup afterward contains one oval seed, crowned with hairy down.

This genus of plants is ranged by Dr. Linnæus in the second section of his nineteenth class; the flowers of this section are composed of hermaphrodite florets in the center, and female in the circumference.

The SPECIES are,

1. AMELLUS (*Lychnitis*) foliis oppositis lanceolatis obtusis, pedunculis unifloris. Lin. Sp. 1276. *Star-flower with spear-shaped obtuse leaves placed opposite, and one flower on each foot-stalk.*
2. AMELLUS (*Umbellatus*) foliis oppositis triplinerviis subtomentosis, floribus umbellatis. Amoen. Acad. 5. p. 407. *Star-flower with opposite leaves having three veins, and flowers in umbels.*

The first sort grows naturally at the Cape of Good Hope. It rises from two to three feet high, sending out branches on every side, garnished with spear-shaped leaves placed opposite, terminated by flower-stalks, each supporting one Violet-coloured flower, with a yellow disk, shaped like those of the Aster, which appear in July or August.

This is a perennial plant, which is easily propagated by cuttings, which, if planted in shade during any of the summer months, and duly watered, will put out roots; these should be taken up with balls of earth to their roots, and planted in pots, that they may be sheltered in winter, either under a common frame, or in a green-house, where they may have plenty of air in mild weather, otherwise they will draw up weak and have little beauty.

The second sort grows naturally in Jamaica; this hath hoary stalks which rise two feet high, sending out side branches, which are garnished with oval leaves placed opposite; the flowers which terminate the branches grow in small umbels, but these have little beauty. It may be propagated by seeds, which should be sown on a hot-bed in the spring; when the plants are fit to remove, two or three of them should be planted in pots, then plunged into a hot-bed of tan, to bring them forward to get ripe seeds in the autumn, otherwise the plants will require a stove in winter.

AMENTACEOUS flowers [of *Amentum*, Lat. a string, thong, or latchet] are such as have an aggregate of summits, hanging down in form of a rope, or cat's tail, which is also called an *Iulus*; as in Willows, Walnuts, Poplars, &c.

AMETHYSTEA. Lin. Gen. 32. Amethystina. Amman. Haller. Amethyst.

The CHARACTERS are,

The flower hath a permanent bell-shaped empalement of one leaf, cut into five equal pointed segments at the brim; the flower is of one leaf, of the lip kind, divided into five unequal parts at the top; the upper leaf is erect, roundish, concave, and cut into two; the lower lip is cut into three parts, the middle segment being concave and of the same length with the upper lip, but the two side segments are shorter and erect. It hath two slender stamina, which stand under the upper lip, but are longer; these are crowned with roundish summits. In the center is situated a quadrifid germen, supporting a single style, crowned with two acute stigma: after the flower is past, the germen becomes four naked seeds, shut up in the empalement.

This genus of plants is by Dr. Linnæus ranged in his second class of plants, entitled Diandria Monogynia, the flower having two stamina and one style.

We know but one SPECIES of this genus, viz.

- AMETHYSTEA. Hort. Upsal. 9. Amethystina montana erecta foliis exiguis digitatis trifidis serratis, flosculis cum comâ è cœruleo-janthinis. Amman. Ruth. 4. i. e. *Mountain upright Amethyst, with small, trifid, sawed leaves, and the beads and flowers of a jacinth blue.*

This plant is a native of the mountains in Siberia,

from whence the seeds were sent to the imperial garden at Peterburgh, where the plants flourished and perfected their seeds, part of which were sent me by the late Dr. Amman, which grew in the Chelsea garden, where the plants annually produce seeds.

It is an annual plant with an upright stalk, which rises about a foot high; toward the top it puts out two or three small lateral branches, garnished with small trifid leaves, sawed on their edges, of a very dark green colour; at the extremity of the branches the flowers are produced in small umbels; they are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel; so that although the flowers are small, yet from their colour with those of the upper part of the stalks, the plants make a pretty appearance, during their continuance in flower. If the seeds of this plant are sown in the autumn, or are permitted to scatter, the plants will come up early the following spring, and these will flower the beginning of June; but those which are sown in the spring, will not flower till July; and in dry seasons, the seeds will remain in the ground a whole year, so that the best time for sowing them is in the autumn.

When the plants come up, they will require no other care but to keep them clean from weeds, and where they are too close to thin them; for they do not thrive when transplanted, therefore the seeds should be sown where they are to remain.

AMMANNIA. Houst. Nov. Gen. Lin. Gen. Plant. 144.

The CHARACTERS are,

It hath a bell-shaped, oblong, erect, permanent empalement, having four angles, and divided at the brim into eight slender parts. The flower hath no petals, but four slender stamina which are as long as the empalement in which they are inserted. These are crowned with double summits. In the center is situated a large round germen, supporting a short style crowned with a stigma; the empalement afterward becomes a round capsule with four cells, which are filled with small seeds.

This genus is by Dr. Linnæus ranged in his fourth class of plants, entitled Tetrandria Monogynia, the flower having four stamina and one style.

The SPECIES are,

1. AMMANNIA (*Latifolia*) foliis semiamplexicaulibus, caule tetragono. Hort. Cliff. 344. *Ammannia with a square stalk, and leaves embracing it half round.* Ammannia palustris, caule quadrangulari foliis angustis. Houst. MSS.
2. AMMANNIA (*Ramosior*) foliis subpetiolatis caule ramosa. Lin. Sp. Plant. 120. *Ammannia with leaves having short foot-stalks and a branching stalk.* Ludvigia aquatica erecta caule rubente, foliis ad genicula binis longis angustis hyssopi instar flore tetrapetalo albo. Clayt.
3. AMMANNIA (*Baccifera*) foliis subpetiolatis capsulis calyce majoribus coloratis. Lin. Sp. Plant. 120. *Ammannia whose leaves have short foot-stalks, and a coloured seed-vessel larger than the flower-cup.*

The first sort grows naturally in moist places in Jamaica, from whence Dr. Houlston sent the seeds to England, which succeeded at Chelsea, and have from thence been distributed to most of the botanic gardens in Europe.

It grows about a foot and a half high, with an upright square stalk, and long narrow leaves set in form of a triangle, whose base half surrounds it; these grow the whole length of the stem. They are of a pale green, and of the consistence of those of Purslane; the stalks are also succulent, and of the same colour with those of that plant. The flowers come out in whorles round the stalks, at the joints where the leaves adhere, in clusters: these have no petals, so make no great appearance, and are soon succeeded by round seed-vessels, which are full of small seeds.

The plant must be raised on a hot-bed in the spring, and afterward removed to another hot-bed to bring it forward. When the plants have acquired strength, they should be transplanted into pots filled with rich

L

light

light earth, and placed under a frame, observing to shade them till they have taken fresh root; then they should be placed in a glass-case or stove to ripen their seeds, for the plants are too tender to thrive in the open air in this country, unless the summer proves very warm.

The second sort grows naturally in Virginia and Carolina; this is an annual plant, which rises about a foot high, with red succulent stalks, putting out side branches, which grow opposite: the flowers are produced single from the wings on the lower part of the branches, but toward the top they are in clusters; these have no beauty, so are only preserved in botanic gardens for the sake of variety. This sort will perfect its seeds in the open air, if the plants are raised on a hot-bed in the spring, and planted in a warm border.

The third sort grows naturally in China; this is a very low plant, seldom rising more than three inches high; the leaves are placed opposite on the branches, and the flowers grow in whorles from the wings of the stalk. As this plant has little beauty, it is rarely preserved in gardens. It must be raised on a hot-bed in the spring, and treated in the same manner as the first sort, with which management the seeds will ripen in England.

AMMI [*Ami*, Gr.] Bishops-weed.

The CHARACTERS are,

It is an umbelliferous plant; the great umbel is composed of many smaller, which are disposed like rays. The outer involucrium is composed of many narrow-pointed leaves, which are almost the length of the umbel. The small umbels have a short many-leaved involucrium. The flowers are disform, each having five petals, which are heart-shaped; those in the outer rays being large and unequal in size, but those in the center, which compose the disk, are nearly equal. The flowers have five slender stamina, which are crowned with roundish summits. In the center of the empalement is situated the germen, supporting two reflexed styles, crowned with obtuse stigma. The germen afterward becomes a small, round, striated fruit, composed of two seeds, which are plain within and convex on their outside.

This genus of plants is by Dr. Linnæus ranged in the second section of his fifth class, entitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. AMMI (*Majus*) foliis inferioribus pinnatis lanceolatis serratis, superioribus multifidis linearibus. Hort. Upsal. 59. *Bishops-weed with under leaves, which are winged, spear-shaped, and sawed, and the upper leaves are divided into many narrow segments. This is the Ammi majus. C. B. P. 159. And the Ammi vulgare. Dod. p. 415. Common Bishops-weed.*
2. AMMI (*Glaucifolium*) foliorum omnium lacinulis lanceolatis. Guett. 2. p. 433. i. e. *Bishops-weed with all its leaves cut in shape of a spear. Ammi petraeum glaucifolium perenne. Mor. Hist. 3. p. 295.*

The first sort is annual; of this there is a variety, which is mentioned by John Bauhin as a distinct species, under the title of Ammi majus foliis plurimum incis & nonnihil crispis; but I have frequently had this variety arise from the seeds of the former, so I have not enumerated it as a different sort.

This plant is propagated by seeds, which should be sown in the autumn in the place where it is to remain; and in the spring, the ground should be hoed to cut up the weeds, and also to thin the plants in the same manner as is practised for Carrots, leaving them four or five inches asunder; or if the ground is good where they grow, they must be left at least six inches, for they will grow large and cover the ground; after this they will require no farther care, but to keep them clean from weeds. In June they will flower, and their seeds will ripen in August, which should be gathered as it ripens, otherwise it will soon scatter. These seeds are used in medicine, so may be had in plenty with this management; for it will grow in any situation that is open, but thrives best on light sandy

land. When the seeds are sown in the spring, they seldom come up the same year; and if they should, those plants will be weak and produce few seeds.

The second sort is a perennial plant, which is preserved in botanic gardens for variety, but having little beauty, is rarely admitted into other gardens. It may be propagated by seeds, which should be sown in the autumn, because those sown in the spring, seldom come up the same year. It will grow in any open situation, is very hardy, and thrives best on a moist soil.

AMMI PERENNE. See SIUM.

AMOMUM. Lin. Gen. Plant. 2. Zinziber. C. B. P. 35. Ginger.

The CHARACTERS are,

The flowers are collected into a scaly spike, each having a double (spatha) or sheath; the outer sheath loosely covers the scale, and the inner encompasses the tube of the flower with the parts of generation: the flower is of one leaf, tubulous below, but divided into three parts at the brim, the middle segment being longer and broader than the others. In the bosom of the flower is situated an oblong thick nectarium. From the tube of the flower arises two slender stamina, which are crowned with thick short summits. Under the receptacle of the flower is placed the round germen, supporting a single style, which is as long as the tube of the flower, crowned with a hairy stigma. The germen afterward becomes an oval three-cornered seed-vessel, opening in three parts, containing several seeds.

This genus of plants is by Dr. Linnæus ranged in his first class, entitled Monandria Monogynia; but it more properly belongs to his second, for the flowers of this have two stamina, one of which is joined to the upper segment of the flower, and this soon loses its summits, so appears to be only a segment. This I have constantly found in all the flowers which I have examined; the flowers have but one style.

The SPECIES are,

1. AMOMUM scapo nudo spica ovato. Hort. Cliff. 3. *Amomum with a naked stalk and oval spike of flowers. Zinziber. C. B. P. 35. Ginger.*
2. AMOMUM scapo nudo spica oblonga obtusa. Hort. Cliff. 3. *Amomum with a naked stalk and an oblong blunt flower-spike. Zinziber latifolium sylvestre. Hort. Lugd. 636. Broad-leaved wild Ginger, called Zerumbet.*
3. AMOMUM scapo bracteis alternis laxis, caule foliorum altissimo. *Amomum with flower-stalks loosely branching alternately, and very tall leaf-stalks.*

The first, which is the common Ginger, is cultivated for sale in most of the islands of America, but is a native of the East-Indies, and also of some parts of the West-Indies, where it is found growing naturally without culture. The dried roots of this sort furnish a considerable export from the British colonies in America. The roots are of great use in the kitchen, as also in medicine; and the green roots preserved as a sweatmeat, are preferable to every other sort.

The roots of this sort are jointed, and spread in the ground; these put out many green reed-like stalks in the spring, which rise to the height of two feet and a half, garnished with long narrow leaves, closely embracing the stalks at their base. The flower-stems afterward arise by the side of these, immediately from the root; these are naked, ending with an oblong scaly spike; from each of these scales is produced a single blue flower, whose petals are but little longer than the squamose covering. The flowers appear in September, and in about a month after the stalks entirely decay, so that the roots remain inactive three or four months.

The second sort grows naturally in India; the roots of this are much larger than those of the first, but are jointed in the same manner. The stalks grow from three, to near four feet high, garnished with oblong leaves, placed alternately, and embrace the stalks at their base. The flower-stems arise immediately from the root; these are terminated by oblong, blunt, scaly heads; out of each scale is produced a single white flower, whose petals extend a considerable length beyond

A M O

beyond their scaly covering. These appear in September, and in November all the stalks perish in the same manner as the Ginger.

The third sort hath thick fleshy roots, resembling those of the large Flag Iris; in the spring these send forth many green reed-like stalks, which rise to the height of seven or eight feet, garnished with very long narrow leaves, set alternately, closely embracing them at their base. The stalks decay entirely in autumn, and new arise from the roots in the spring, but it hath not produced any flowers as yet in England, though the roots thrive and increase greatly where they are properly managed.

All these sorts are tender, and require a warm stove to preserve them in this country. They are easily propagated by parting of their roots; the best time for doing this is in the spring, before they put out new shoots; for they should not be transplanted in summer when they are in full vigour, nor do they succeed so well when they are removed in autumn, because they remain long after in an inactive state; and during that time, if wet comes to the roots, it often causes them to rot. When the roots are parted, they should not be divided into small pieces, especially if they are designed to have flowers; for until the roots have spread to the side of the pots, they rarely put out flower-stems, for which reason they should not be planted in very large pots.

These plants thrive best in a light rich earth, such as may be found in the kitchen-garden; with this the pots should be filled within two inches of the top, then the roots should be placed in the middle of the pots, observing that their crowns are upwards, and the pots filled up with the same rich earth; after this the pots should be plunged into a hot-bed of tanners bark, and must be sparingly watered, until their stalks appear above ground, when they will require a greater share of moisture, especially during the warm summer months; but in autumn the waterings must not be often, nor in great plenty; and during the winter season, when the roots are inactive, very little water should be given them. The pots with these roots should constantly remain plunged in the tan-bed, for if they are taken out and placed on shelves in the stove, their fibres frequently shrink, which often occasions the roots to decay.

With this management all these sorts have multiplied greatly with me, and the common Ginger has produced roots which have weighed five or six ounces, but the others have been near a pound weight.

AMOMUM PLINII. See SOLANUM.

AMORIS POMUM. See LYCOPERSICON.

AMORPHA. Lin. Gen. Plant. 768. Bastard Indigo.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubulous, cylindrical, and cut into five small obtuse parts at the brim. The flower is of the butterfly kind; the upper petal, or standard, is small, concave, and erect; this is inserted between the two upper segments of the empalement. It hath ten stamina, joined at their base, of unequal lengths, and crowned with summits; in the center is situated a roundish germen, supporting an awl-shaped style, which is the length of the stamina, and crowned with a single stigma; the germen afterward becomes a reflexed moon-shaped pod, having one cell, in which are lodged two kidney-shaped seeds.

This genus is by Dr. Linnæus ranged in his seventeenth class of plants, entitled Diadelphia Decandria; the flowers of this class have ten stamina, nine of which are joined, and one stands off.

We know but one SPECIES of this genus, viz.

AMORPHA (Fruticosa). Hort. Cliff. 353. Bastard Indigo. Barba Jovis Americana pseudoacaciæ foliis flosculis purpureis minimis. Cat. Hort. Chelf. 11.

This shrub grows naturally in Carolina, where formerly the inhabitants made a coarse sort of Indigo from the young shoots, which occasioned their giving it the title of Bastard Indigo.

It rises with many irregular stems, to the height of

A M Y

twelve or fourteen feet, garnished with very long winged leaves, in shape like those of the common Acacia. At the extremity of the same year's shoots, the flowers are produced in long slender spikes, which are small, and of a deep purple colour; the stamina stand out beyond the petals, and are crowned with yellow summits; after the flowers are past, the germen turns to a short pod, having two kidney-shaped seeds, but these do not ripen in England.

The seeds of this plant were sent to England from Carolina, by Mr. Mark Catesby, F. R. S. in 1724, from which many plants were raised in the gardens near London; these were of quick growth, and many of the plants produced flowers in three years. At present it is become very common in all the gardens and nurseries; where it is propagated as a flowering shrub, for the ornament of the shrubbery. It is generally propagated by seeds, which are annually sent to England from different parts of America; for it is found in many of the northern colonies there, and it may also be propagated by laying down of the young branches, which in one year will make good roots, and may then be taken off and planted either in the nursery, or the places where they are designed to remain. If they are put into a nursery, they should not remain there more than one year; for as the plants make large shoots, they do not remove well when they have remained long in a place: they must have a sheltered situation, otherwise their branches will be broken by the winds. As these shoots are large and soft, their upper parts are generally killed by frost in winter, but they put out shoots again in plenty below the dead part the spring following.

AMPHITHEATRE [*Ἀμφιθέατρον* of *ἀμφί*, around, and *θέατρον*, to view, Gr.] or temples of view erected on a double rising, were esteemed great ornaments to a large and noble garden. If this hill, or rising ground, is of a semicircular figure, it will be still the better.

These amphitheatres are sometimes formed of Evergreens, as Hollies, Phillyreas, Laurustinuses, Bays, &c. observing to plant the shortest growing shrubs in the front, and the tallest trees behind, as Pines, Firs, Cedars of Lebanon, &c.

They are also formed of slopes on the sides of hills, and covered with turf, but are now generally excluded by all persons of true taste; for the natural easy slope of such hills, is infinitely more beautiful than the stiff angular slopes into which these amphitheatres are commonly cut.

AMYGDALUS. Lin. Gen. Plant. 545. [*Ἀμύγδαλος*, Gr.] The Almond-tree.

The CHARACTERS are,

It hath a tubulous empalement of one leaf, which is cut at the brim into five obtuse segments; the flower hath five oval, obtuse, concave petals, which are inserted in the empalement; in the center of the outer flower is situated a roundish hairy germen, supporting a single style the length of the stamina, which is crowned by a round stigma; this is attended by a great number of slender erect stamina, which in many species are not so long as the petals of the flower, these are crowned with slender summits. After the flower is past, the germen becomes an oval, compressed, large fruit, with a thin, tough, hairy covering, having a longitudinal furrow; this opens and falls away, leaving an oval compressed nut, which is furrowed and netted, inclosing a single seed of the same form.

Dr. Linnæus has joined to this genus the Persica, or Peach-tree, making them only different species, ranging it in his twelfth class, entitled Icosandria Monogynia; the flowers having from twenty to thirty stamina, which are inserted to the empalement.

The SPECIES are,

1. AMYGDALUS (Communis) foliis petiolatis serratis petalis florum emarginatis. Almond-tree with sawed leaves, having foot-stalks, and the petals of the flower indented. Amygdalus fativa. C. B. P. 441. Common Almond-tree.
2. AMYGDALUS (Dulcis) foliis petiolatis marginibus crenatis, corollis calyce vix longioribus. Almond-tree with

with crenated leaves, having foot-stalks, and the petals of the flowers no longer than the empalement. *Amygdalus dulcis putamine molliori*. C. B. P. 441. Commonly called *Jordan Almond*.

3. *AMYGDALUS (Sativus)* foliis lineari-lanceolatis acuminatis, marginibus crenatis. *Almond-tree with pointed, narrow, spear-shaped leaves, crenated on their edges.* *Amygdalus sativa flore albo*.

4. *AMYGDALUS (Orientalis)* foliis lanceolatis integerimis, argenteis perennantibus petiolo brevioribus. *Almond-tree with spear-shaped silvery leaves, which are entire, and continue all winter, and very short foot-stalks.* *Amygdalus Orientalis foliis argenteis splendentibus.* Du Hamel.

5. *AMYGDALUS (Nana)* foliis petiolatis ferratis basi attenuatis. *Almond with sawed leaves, which are narrowed at the foot-stalk.* *Amygdalus Indica nana.* Pluk. Alm. 28. tab. 11. *Dwarf Almond with single flowers.* The first is the common Almond, which is cultivated more for the beauty of its flowers, than for its fruit. There are two varieties of this, one with sweet, the other bitter kernels, which often arise from the fruit of the same tree.

The second sort is commonly known by the title of *Jordan Almonds*; the nuts of this kind are frequently brought to England; these have a tender shell, and a large sweet kernel. The leaves of this tree are broader, shorter, and grow much closer than those of the common sort, and their edges are crenated. The flowers are very small, and of a pale colour, inclining to white. I have several times raised these trees from the Almonds which came from abroad, and always found the plants to maintain their difference from the common Almond.

The third sort hath narrow sharp-pointed leaves, which are sawed on their edges; the flowers are much smaller than those of the common Almond, and are white; the shoots of this tree are smaller, and the joints closer than those of the common sort, nor is the tree so hardy, therefore should have the advantage of a warm situation, otherwise it will not thrive. This sort flowers early in the spring, and rarely produces fruit in England. But from an old tree which grew against a south-west aspect wall, I have some years had the fruit ripe, which were well flavoured, but their kernels were small.

The fourth sort was found growing near Aleppo, from whence the fruit was sent to the duke D'Ayen in France, who raised several of the plants in his curious garden at St. Germain, and was so good as to send me a share of them, which are flourishing in the Chelsea garden, where they have endured the open air for some years, against a wall, without any covering. The leaves of this tree are silvery, and very like those of the Sea Purslane. These continue most of the year; the flowers are very small, and have not been succeeded by fruit yet in England. I can give no farther account of its difference from the other sorts.

The fifth sort is very common in the nurseries about London, and is usually sold with other flowering shrubs to adorn gardens: this seldom rises more than three feet high, sending out many side branches. The roots of this are very subject to put out suckers, by which it may be increased in plenty, but if these are not annually taken away, they will starve the old plants. As these suckers are very apt to creep at the root, and put out suckers again, those plants which are propagated by layers are much preferable. This shrub flowers in April, at which time all the young shoots are covered with flowers, which are of a Peach blossom, and make a fine appearance when intermixed with shrubs of the same growth.

The common Almond is cultivated in all the nurseries, and the trees are generally planted for the beauty of their flowers. These often appear in February, when the spring is forward, but if frost comes after, the flowers are soon destroyed, so that their beauty is of short duration, and in such seasons there are few of the Almonds which bear fruit; whereas, when the

trees do not flower till March, they seldom fail to bear plenty of fruit, many of which will be very sweet, and fit for the table when green, but they will not keep long.

They are propagated by inoculating a bud of these trees into a Plumb, Almond, or Peach stock, in the month of July (the manner of this operation see under the article of INOCULATION). The next spring, when the buds shoot, you may train them up either for standards, or suffer them to grow for half standards, according to your own fancy; though the usual method is to bud them to the height the stems are intended to be; and the second year after budding, they may be removed to the places where they are to remain. The best season for transplanting these trees, if for dry ground, is in October, as soon as the leaves begin to decay; but for a wet soil, February is much preferable, and observe always to bud upon Plumb stocks for wet ground, and Almonds and Peaches for dry.

ALMOND, the Dwarf, with double flowers. See PERSICA.

AMYRIS. See TOXICODENDRON.

ANACAMPSEROS. See SEDUM.

ANACARDIUM. Lin. Gen. Plant. 467. Acajou. Tourn. Init. R. H. 658. tab. 435. The Cashew-nut, or Acajou.

The CHARACTERS are,

It hath an empalement of one leaf, which is erect, and cut into five acute segments at the brim. The flower is of one leaf, having a short tube, cut into five parts at the top, which are reflexed, and are longer than the empalement; the flower hath ten slender stamina, which are as long as the petal, crowned with small summits. In the center is placed a round germen, supporting an awl-shaped style, crowned with an acute stigma. The germen afterward becomes a large, oval, fleshy fruit, having a large kidney-shaped nut growing to its apex.

This genus of plants is by Dr. Linnæus ranged in the first section of his tenth class, entitled Decandria Monogynia; the flowers of this having ten stamina and a single style.

We have but one SPECIES of this genus, viz.

ANACARDIUM (Occidentale) Hort. Cliff. 161. the occidental *Anacardium*, or *Cashew*. Acajou. Pis. Hist. Bras. 58.

This tree grows to the height of twenty feet or more, in its native country, which is both Indies, but in England the plants are with great difficulty preserved; though by their first shoot from the seeds, they appear so strong and vigorous, as to promise a much greater progress than they are ever seen to make.

They are easily raised from the nuts, which are annually brought from America in great plenty; each of these should be planted in a small pot filled with light sandy earth, and plunged into a good hot-bed of tanners bark, being careful to prevent their having wet, till the plants come up, for the nuts frequently rot with moisture. The reason of my advising the nuts to be each put into a separate pot, is, because the plants seldom live when they are transplanted. If the nuts are fresh, the plants will come up in about a month after planting, and in two months more they will be four or five inches high, with large leaves; from this quick growth, many persons have been deceived by supposing them hardy, and that they would continue the like progress, whereas they seldom advance much farther the same year.

The plants must be constantly kept in the stove, for they are too tender to live abroad in England, in the warmest season of the year, nor will they thrive in a common green-house in summer. As these plants abound with a milky acrid juice, they should have but little water, even in summer; and in winter, if they are sparingly watered once in a fortnight, it will be sufficient, for their roots are tender and soon perish with moisture.

When these plants are transplanted, it will be the best method to break the pots, for the roots do not put out many fibres to hold the earth about them, so that in shaking them out of the pots, most of the earth

will fall away from their roots, and when this happens, the plants seldom survive it; therefore in breaking of the pots, the same caution must be had not to disturb the earth more than can be avoided; then the plant, with the ball of earth to its roots, should be put into a pot one size larger than that in which it had before grown, filling up the pot with light sandy earth, and plunge the pots again into the hot-bed. These plants should not be removed oftener than once a year, nor should they be put into large pots, for unless their roots are confined, they will not thrive.

With this management I have kept these plants several years, but they are of slow growth after the first season, so that I have not raised any of them more than two feet and a half high, and it is very rare to see them in England more than half that height, though I have seen two of them in flower, one in the late Sir Charles Wager's garden at Parsons-green, and the other in Chelsea garden.

The pulpy fruit, to whose apex this nut grows, is as large as an Orange, and is full of an acid juice, which is frequently mixed in the making of punch in America. Many of these fruit have been brought to England, in casks of rum for the same purpose.

The nut is of the size and shape of a hare's kidney, but is much larger at the end which is next the fruit, than at the other. The outer shell is of an Ash colour, and very smooth; under this is another which covers the kernel, between these there is a thick black inflammable oil, which is very caustic; this will raise blisters on the skin, and has often been very troublesome to those who have incautiously put the nuts into their mouths to break the shell.

The milky juice of this tree will stain linen of a deep black, which cannot be washed out again; but whether this has the same property with that of the eastern Anacardium, has not yet been fully experimented; for the inspissated juice of that tree is the best sort of lac, which is used for staining of black in China and Japan.

Dr. Grew mentions the juice being used for staining of cottons, but it is doubtful which of the species he means; though Sir Hans Sloane supposes it to be of the Acajou here mentioned. However, it may be very well worth the trial; if the inhabitants of the British islands in America would tap a few of the trees in the bleeding season, and collect the juice in earthen pots, keeping it in a place free from dust, or covering the pots over with a linen cloth, to prevent dust from mixing with it, and when it is of a proper consistence, some trials may be made with it, to see if it has the same property with the Japan lac, which if it has, may prove a valuable commodity.

ANACYCLUS. Lin. Gen. Plant. 869. Santolinoides. Vall. Acad. Scien.

The CHARACTERS are,

It hath compound flowers, consisting of female and hermaphrodite florets, included in one common scaly empalement; the rays or borders being formed of the female florets, which are tubulous, and stretched out in the form of a tongue beyond the empalement. The hermaphrodite florets which compose the disk, are funnel-shaped, quinquefid, and spread open; these have each five slender stamina, which are crowned with cylindrical summits; in the center is placed an oblong compressed germen, supporting a slender style, crowned with bifid stigma. The female florets have an oblong membranous germen, supporting a slender style, crowned with two slender reflexed stigma; the hermaphrodite florets are succeeded by one oblong compressed seed. The female florets are succeeded by a single oblong seed with broad borders or wings, which are indented at the top; these are placed on a convex receptacle.

This genus of plants is ranged by Dr. Linnæus in the third section of his nineteenth class, entitled Syngenesia Polygamia superflua. The plants of this division have female and hermaphrodite flowers included in the same common empalement.

The SPECIES are,

1. **ANACYCLUS** (*Creticus*) foliis decompositis linearibus laciniis divisis planis. Hort. Cliff. 417. *Anacyclus*

with narrow decomposed leaves, whose divisions are plain. Cotula cretica minima chamæmeli folio capite inflexo. Tourn. Cor. 37.

2. **ANACYCLUS** (*Orientalis*) foliis compositis setaceis acutis rectis. Hort. Cliff. 417. *Anacyclus with compound, bristly, upright, pointed leaves. Chamæmelum Orientale foliis pinnatis. Tourn. Cor. 37.*

3. **ANACYCLUS** (*Valentinus*) foliis decompositis linearibus laciniis divisis tretiusculis acutis floribus flosculosis. Hort. Cliff. 417. *Anacyclus with decomposed narrow leaves, whose divisions are taper and pointed, and floscular flowers. Chrysanthemum Valentinum. Clus. Hist. 1. p. 332.*

The two first sorts grow naturally in the islands of the Archipelago, from whence Dr. Tournefort sent their seeds to the royal garden at Paris. I have also received the seeds of both these plants from Portugal, so that it may also grow naturally there, as do many of those plants which were discovered by Tournefort in the Levant. These are low plants, whose branches trail on the ground. The first sort has fine cut leaves like those of Chamomile; the flowers are small, white, and grow single, with their heads declining; these are like those of the common Mayweed. The second hath winged leaves like those of the Ox-eye; the flowers are white, and like those of Chamomile.

The third sort grows naturally in Spain, from whence I have received the seeds. This grows a foot and half high, sending out many side branches; the leaves are finely divided like those of Chamomile, and are hairy: the flowers grow single at the extremity of the branches, and are of a bright yellow colour, with a silvery scaly empalement. These are as large as those of the Ox-eye.

All these plants are annual: the seeds should be sown early in the spring in a border of light earth, where they are designed to remain, and require no other care but to keep them clean from weeds, and thin the plants where they are too close. As these have no great beauty, a few plants only may be left for the sake of variety. They flower in July and August, and their seeds ripen in September.

ANAGALLIS. Lin. Sp. Plant. 189. Pimpernel.

The CHARACTERS are,

The empalement is permanent, cut into five sharp segments, which are hollow. The flower is of one leaf spread open, and cut into five parts at the brim; it hath five erect stamina which are shorter than the petals, and are crowned with single summits. In the center is placed the globular germen, supporting a slender inclining style crowned with a blunt stigma. The germen afterward becomes a globular vessel with one cell, opening horizontally, in which are lodged several angular seeds.

This genus of plants is by Dr. Linnæus ranged in the first division of his fifth class, entitled Pentandria Monogynia, the flowers having five stamina and one style.

The SPECIES are,

1. **ANAGALLIS** (*Arvensis*) foliis indivisis caule procumbente. Lin. Gen. Plant. 148. *Pimpernel with undivided leaves and a trailing stalk. Anagallis Phœnicio flore. C. B. P. 252.*

2. **ANAGALLIS** (*Fœmina*) foliis indivisis glaucis caule procumbente flore cæruleo. *Pimpernel with undivided glaucous leaves, a trailing stalk, and blue flower. Anagallis cæruleo flore. C. B. P. 252.*

3. **ANAGALLIS** (*Monelli*) foliis indivisis caule erecto. Lin. Sp. Plant. 148. *Pimpernel with an undivided leaf and upright stalk. Anagallis tenuifolia Monelli. Clus. App.*

4. **ANAGALLIS** (*Latifolia*) foliis cordatis amplexicaulibus, caulibus compressis. Lin. Sp. Plant. 149. *Pimpernel with heart-shaped leaves, embracing the stalks which are compressed. Anagallis Hispanica latifolia flore cæruleo. Horteg.*

The first sort is very common in fields, and other cultivated places, in most parts of England. The second sort is sometimes found wild in the fields, but is less common than the first in England. This is supposed to be only a variety of the first, but from

thirty years cultivating it, I can affirm it never alters; and the plants before they shew their flowers are so different, as to be easily distinguished from the first. There is a variety of this with a deeper blue flower, whose seeds I received from Nice, and this hath retained its colour for three years, during which time I have sown it in the Chelsea garden.

These are all annual plants which arise from seeds, and, if suffered to remain till their seeds scatter, will become weeds in the place; so that they are never cultivated, except in botanic gardens for variety. The first and second sorts are directed by the College of Physicians for medicinal use.

The third sort is a very beautiful, small, perennial plant, producing great numbers of fine blue flowers, in April and May: this may be propagated by seeds, which should be sown soon after they are ripe; for if they are kept till spring, they do not always succeed: this plant requires to be sheltered from extreme cold, which will sometimes destroy it in winter.

The fourth sort was sent me from Spain by Mr. Hor-tega, intendant of the royal gardens at Madrid. This is a trailing annual plant, with broad leaves and blue flowers. It will easily rise from seeds, and requires no other care but to keep the plants clean from weeds.

There are two varieties of the first sort, one with a white, and the other a flesh-coloured flower; but as they are not constant, I have not inserted them as different species. There is also another with a worn-out purple flower, which has several years continued the same in the Chelsea garden; but as there is little difference in the leaves of this and the first, I have not enumerated it.

ANAGYRIS, Stinking Bean-trefoil.

The CHARACTERS are,

It hath a bell-shaped empalement, which is cut into five parts at the brim, the upper segment being much deeper cut than the others. The flower is of the butterfly kind, the standard is heart-shaped, upright, broad, and indented. This is much longer than the empalement; the wings are oblong, plain, and longer than the standard; the keel is long and upright: it hath ten stamina, which rise distinct, and are equal, crowned with single summits. In the center is placed an oblong germen, supporting a single style, having a hairy stigma. The germen afterward becomes a large oblong pod, which is reflexed at the point, in which is lodged several kidney-shaped seeds.

Dr. Linnæus ranges this genus in his tenth class of plants, entitled Decandria Monogynia, the flower having ten stamina, and one style.

The SPECIES are,

1. ANAGYRIS (*Fœtida*) foliis ovatis floribus lateralibus. *Stinking Bean-trefoil with oval leaves, and flowers proceeding from the wings of the stalks. Anagyris fœtida. C. B. P. 391.*
2. ANAGYRIS (*Cretica*) foliis oblongis racemis longioribus. *Stinking Bean-trefoil with oblong leaves, and longer spikes of flowers. Anagyris fœtida Cretica oblongis foliis luteis floribus. Barrel. Icon.*

The first sort grows wild in the south of France, in Spain and Italy: this is a shrub which usually rises to the height of eight or ten feet, and produces its flowers in April and May, which are of a bright yellow colour, growing in spikes, somewhat like those of the Laburnum: the seeds are never perfected in this country, which is the reason of its present scarcity in England.

The other sort is a native of Candia, and some of the islands of the Archipelago, and at present very rare in the English gardens. This sort hath longer leaves than the former, and flowers later in the summer, so that it never produces seeds.

These may be both propagated by laying down their tender branches in the spring, observing to tongue them in the same manner as the layers of Carnations, being careful in dry weather to supply them with water; which if duly performed, the layers will have taken root by the following spring, when they should be cut off from the old plants, a little time before

they begin to put out their leaves, and planted in a warm situation; for if they are too much exposed to cold winds, they will be in danger of being destroyed in a hard winter. This method of propagating these plants, is to supply their defect in not producing ripe seeds in this country; for the plants which are produced from seeds, will be much handsomer, and will rise to a much greater height.

If you propagate these plants from seeds, you should sow them on a moderate hot-bed the beginning of March. If the seeds are good, the plants will appear in a month after the seeds are sown; when they should be inured by degrees to the open air, into which they should be removed toward the end of May, placing them in a sheltered situation; for this purpose the seeds should be sowed in pots, and plunged into a hot-bed, because the plants do not bear transplanting well till the spring following: and as they are impatient of cold while young, so the two first winters it will be proper to shelter them under a common frame, where the glasses may be drawn off every day in mild weather, that the plants may enjoy the open air, which will prepare them for planting abroad when they have acquired proper strength: it will be very proper to keep these plants in pots three years, in which time they will have advanced to be in proper condition for planting them into the places where they are intended to remain; the best time for this is about the beginning of April, just before the plants begin to put out new leaves: at which time they should be turned out of the pots, preserving good balls of earth to their roots, planting some of them against warm aspected walls, where they will not be in danger of suffering by frost; and the others may be planted in warm situations, where, if they are protected in severe winters, by covering the surface of the ground about their roots with tanners bark, and screening their heads with mats, they may be preserved several years. The fourth year from seeds these plants will begin to produce their flowers, and will continue flowering every year after, so will be very proper to intermix with other flowering shrubs of the same growth in warm situations.

ANANAS, the Pine-apple.

The CHARACTERS are,

The flower consists of three oval petals, which are produced from the protuberances of the pyramidal fruit, and are stretched out beyond the empalement. These have six awl-shaped stamina, which stand within the flower, crowned with spear-shaped summits: the germen is situated below the flower, supporting a slender style, crowned with a trifid stigma. The germen afterward becomes a cell, in which is lodged several angular seeds.

Dr. Linnæus has joined this to the Bromelia of father Plumier, to which he has also added the Karatas of the same author, supposing them to be of the same genus; which mistake he may have been led into by Plumier's figures, for he has joined the fruit of the Caraguata to the flowers of the Karatas, and vice versa. The other differences will be exhibited under the article Karatas.

The VARIETIES of this are,

1. ANANAS (*Ovatus*) aculeatus, fructu ovato, carne al-bida. Plum. *Oval-shaped Pine-apple, with a whitish flesh.*
2. ANANAS (*Pyramidalis*) aculeatus, fructu pyramidato, carne aurea. Plum. *Pyramidal Pine-apple, with a yellowish flesh, called the Sugar-loaf Pine.*
3. ANANAS (*Glabra*) folio vix serrato. Boerh. Ind. Alt. 2. 83. *Pine-apple with smooth leaves.*
4. ANANAS (*Lucidus*) lucide virens, folio vix serrato. Hort. Elth. *Pine-apple with shining green leaves, and scarce any spines on their edges.*
5. ANANAS (*Serotinus*) fructu pyramidato olivæ colore, intus aureo. *Pyramidal Olive-coloured Pine-apple, with a yellow flesh.*
6. ANANAS (*Viridis*) aculeatus, fructu pyramidato ex viridi flavescente. *The green Pine-apple.*

There are several other varieties of this fruit, some of which may have been obtained from seeds; and I doubt

doubt not but if the seeds were sown frequently, in the countries where they are in plenty, there may be as great variety of these fruit, as there are of Apples or Pears in Europe. And this I have found true by some trials which I have made by sowing the seeds, which have always produced a variety of sorts from those of the same fruit.

This fruit (which is justly esteemed for the richness of its flavour, as it surpasses all the known fruits in the world), is produced from an herbaceous plant, which hath leaves somewhat resembling those of Aloe, and are, for the most part, sawed on their edges, but are much thinner, and not so juicy as the Aloe: the fruit resembles the cones of the Pine-tree, from whence it is supposed to have its name.

Where this plant is a native, I believe is hard to determine; but it is probably an indigenous plant in Africa, where, I have been informed, they grow in uncultivated places in great plenty. They have been long cultivated in the hottest islands of the West-Indies, where they are in great plenty, and extraordinary goodness; but they have not been many years in the European gardens, so as to produce fruit: the first person who succeeded in this affair, was Monsieur Le Cour of Leyden in Holland, who, after a great many trials, with little or no success, did at length hit upon a proper degree of heat and management, so as to produce fruit equally good (though not so large) as those which are produced in the West-Indies, as hath been often affirmed by persons who have lived many years there: and it is to this worthy cultivator of gardening, who did not spare any pains or expence to accomplish it, that all the lovers thereof are obliged, for introducing this king of fruits amongst them; and it was from him that our gardens in England were first supplied, though we have since had large quantities brought from America. I cannot here avoid taking notice of a common error which prevails amongst many people, which is, that the plants brought from America are not so good as those which came from M. Le Cour; which is a great mistake, for were the people who send over these plants from America careful to send the best kinds, there would be found many better than those cultivated by M. Le Cour, who had his from thence at first, as his gardener assured me; and I have seen as good fruit produced from American plants, as any I have yet seen, and some three times larger than any I saw in M. Le Cour's garden.

The first sort is the most common in Europe; but the second sort is much preferable to it, the fruit of this being larger, and much better flavoured: the juice of this sort is not so astringent as that of the first, so that this fruit may be eaten in greater quantity with less danger. This frequently produces suckers immediately under the fruit, whereby it may be increased much faster than the common sort; so that in a few years, it may be the most common sort in England.

The third sort is preserved by some curious persons for the sake of variety, but the fruit is not worth any thing. The sixth sort is at present the most rare in Europe, there being very few of the plants at present. This has been esteemed the best sort known, by some of the most curious persons in America, many of whom have thrown out all the other sorts from their gardens, and cultivate only this kind. The plants of this sort may be procured from Barbadoes and Montserrat, in both which places it is cultivated.

The sort with very smooth grass-green leaves, was raised from seeds taken out of a rotten fruit, which came from the West-Indies to the late Henry Heathcote, Esq; from whom I received one plant, which hath produced large fruit: this, I am told, is what the people of America call the King Pine. I have since raised some plants of this kind from seeds, which were brought me from Jamaica.

These plants are propagated by planting the crowns which grow on the fruit, or the suckers which are produced either from the sides of the plants, or under

the fruit, both which I have found to be equally good; although by some persons the crown is thought preferable to the suckers, as supposing it will produce fruit sooner than the suckers, which is certainly a mistake; for by constant experience I find the suckers (if equally strong) will fruit as soon, and produce as large fruit as the crowns.

The suckers and crowns must be laid to dry in a warm place for four or five days, or more (according to the moisture of the part which adhered to the old fruit;) for if they are immediately planted, they will rot, especially the crowns. The certain rule of judging when they are fit to plant, is by observing if the bottom is healed over and become hard; for if the suckers are drawn off carefully from the old plants, they will have a hard skin over the lower part, so need not lie so long as the crowns, or those whose bottoms are moist. But whenever a crown is taken from the fruit, or the suckers from old plants, they should be immediately divested of their bottom leaves, so high as to allow depth for their planting; so that they may be thoroughly dry and healed in every part, lest when they receive heat and moisture, they should perish, which often happens when this method is not observed. If these suckers or crowns are taken off late in the autumn, or during the winter, or early in the spring, they should be laid in a dry place in the stove, for a fortnight or three weeks before they are planted, but in the summer season they will be fit for planting in a few days.

As to the earth in which these should be planted, if you have a rich good kitchen-garden mould, not too heavy, so as to detain the moisture too long, nor over light and sandy, it will be very proper for them without any mixture: but where this is wanting, you should procure some fresh earth from a good pasture; which should be mixed with about a third part of rotten neats dung, or the dung of an old Melon or Cucumber-bed, which is well consumed. These should be mixed six or eight months at least before they are used, but if it be a year, it will be the better; and should be often turned, that their parts may be the better united, as also the clods well broken. This earth should not be screened very fine, for if you only clear it of the great stones, it will be better for the plants than when it is made too fine. You should always avoid mixing any sand with the earth, unless it be extremely stiff, and then it will be necessary to have it mixed at least six months or a year before it is used; and it must be frequently turned, that the sand may be incorporated in the earth; so as to divide its parts: but you should not put more than a sixth part of sand, for too much sand is very injurious to these plants.

In the summer season, when the weather is warm, these plants must be frequently watered, but you should not give them large quantities at a time: you must also be very careful, that the moisture is not detained in the pots, by the holes being stopped, for that will soon destroy the plants. In very warm weather they should be watered twice or three times a week; but in a cool season, once a week will be often enough: and during the summer season, you should once a week water them gently all over their leaves, which will wash the filth from off them, and thereby greatly promote the growth of the plants.

There are some persons who frequently shift these plants from pot to pot, but this is by no means to be practised by those who propose to have large well flavoured fruit; for unless the pots be filled with the roots, by the time the plants begin to shew their fruit, they commonly produce small fruit, which have generally large crowns on them, therefore the plants will not require to be potted oftener than twice in a season: the first time should be about the end of April, when the suckers and crowns of the former year's fruit (which remained all the winter in those pots in which they were first planted) should be shifted into larger pots, i. e. those which were in halfpenny, or three-farthing pots, should be put into penny, or at

at most three-halfpenny pots, according to the size of the plants; for you must be very careful not to over-pot them, nothing being more prejudicial to these plants. The second time for shifting of them is in the beginning of August, when you should shift those plants which are of a proper size for fruiting the following spring, into two-penny pots, which are full large enough for any of these plants. At each of these times of shifting the plants, the bark-bed should be stirred up, and some new bark added, to raise the bed up to the height it was at first made; and when the pots are plunged again into the bark-bed, the plants should be watered gently all over their leaves, to wash off the filth, and to settle the earth to the roots of the plants. If the bark-bed be well stirred, and a quantity of good fresh bark added to the bed, at this latter shifting, it will be of great service to the plants; and they may remain in the same tan until the beginning of November, or sometimes later, according to the mildness of the season, and will require but little fire before that time. During the winter season these plants will not require to be watered oftener than once a week, according as you find the earth in the pots to dry: nor should you give them too much at each time, for it is much better to give them a little water often, than to over-water them, especially at this season.

You must observe never to shift those plants which shew their fruit, into other pots; for if they are removed after the fruit appears, it will stop their growth, and thereby cause the fruit to be smaller, and retard its ripening, so that many times it will be October or November before the fruit is ripe; therefore you should be very careful to keep the plants in a vigorous growing state, from the first appearance of the fruit, because upon this depends the goodness and size of the fruit; for if they receive a check after this, the fruit is generally small and ill tasted.

When you have cut off the fruit from the plants, whose kind you are desirous to propagate, you should trim the leaves, and plunge the pots into a moderate hot-bed, observing to refresh them frequently with water, which will cause them to put out suckers in plenty; so that a person may be soon supplied with plants enough of any of the kinds, who will but observe to keep the plants in health.

There is not any thing which can happen to these plants of a more dangerous nature, than to have them attacked by small white insects, which appear at first like a white mildew, but soon after have the appearance of lice: these attack both root and leaves at the same time, and if they are not soon destroyed, will spread over a whole stove in a short time; and in a few weeks will entirely stop the growth of the plants, by sucking out the nutritious juice, so that the leaves will appear yellow and sickly, and have generally a great number of yellow transparent spots all over them. These insects, after they are fully grown, appear like bugs, and adhere so closely to the leaves, as not to be easily washed off, and seem as if they had no life in them. They were originally brought from America upon the plants which were imported from thence, and I believe they are the same insects which have destroyed the sugar canes of late years in some of the Leeward islands. Since they have been in England, they have spread greatly in such stoves, where there has not been more than ordinary care taken to destroy them. They have also attacked the Orange-trees in many gardens near London, and have done them incredible damage; but I do not find they will endure the cold of our climate in winter, so that they are never found on such plants as live in the open air. The only method I have been yet able to discover for destroying these insects, is by washing the leaves, branches, and stems, of such plants as they attack, frequently with water, in which there has been a strong infusion of Tobacco-stalks, which I find will destroy the insects, and not prejudice the plants. But this method cannot be practised on the Ananas plants, because the insects will fasten themselves so

low between the leaves, that it is impossible to come at them with a sponge to wash them off; so that if all those which appear to fight are cleared off, they will soon be succeeded by a fresh supply from below, and the roots will be also equally infested with them. Therefore, wherever these insects appear on the plants, the safest method will be, to take the plants out of the pots, and clear the earth from the roots; then prepare a large tub, which should be filled with water, in which there has been a strong infusion of Tobacco-stalks; into this tub you should put the plants, placing some sticks across the tub, to keep the plants immersed in water. In this water they should remain twenty-four hours; then take them out, and with a sponge wash off all the insects from the leaves and roots, which may be easily effected when the insects are killed by the infusion; then cut off all the small fibres of the roots, and dip the plants into a tub of fair water, washing them therein, which is the most effectual way to clear them from the insects. Then you should pot them in fresh earth, and having stirred up the bark-bed, and added some new tan to give a fresh heat to the bed, the pots should be plunged again, observing to water them all over the leaves (as was before directed) and this should be repeated once a week during the summer season; for I observe these insects always multiply much faster where the plants are kept dry, than in such places where the plants are sometimes sprinkled over with water, and kept in a growing state. And the same is also observed in America, for it is in long droughts that the insects make such destruction in the sugar canes. And in those islands where they have had several very dry seasons of late, they have increased to such a degree, as to destroy the greatest part of the canes in the islands, rendering them not only unfit for sugar, but poison the juice of the plant, so as to disqualify it for making rum, whereby many planters have been ruined.

As these insects are frequently brought over from America on the Ananas plants which come from thence, those persons who procure their plants from thence, should look carefully over them when they receive them, to see they have none of these insects on them; for if they have, they will soon be propagated over all the plants in the stove where these are placed: therefore, whenever they are observed, the plants should be soaked (as was before directed) before they are planted into pots.

It was formerly the common practice of those persons, who cultivated this fruit in Europe, to build dry stoves, in which they kept their plants in winter, placing the pots on scaffolds (after the manner in which Orange-trees are placed in a green-house), and in the summer to place them in hot-beds of tanners bark under frames. This was the method practised in Holland for raising this fruit, which by Monsieur Le Cour's gardener was first taught those persons, whom his master was so kind as to send the plants. But as the culture of these plants have since become general in England, there has been great improvements made, not only in the contrivances of the stoves, but also in the culture of the plants. For by the former method, the plants were kept upon shelves at least four or five months, whereby the extreme fibres of their roots became dry and hard; for if the plants were too often watered, it occasioned their rotting; so that during the winter season, when the plants should be preparing their fruit for the next summer, they were at a stand, making little or no progress, whereby the fruit did not appear early enough in the spring to ripen in summer, nor were the fruit so large.

Therefore, to remedy this inconvenience, it is now the practice of those persons who are desirous to propagate the fruit, to erect low stoves, with pits therein for the hot-bed, in the manner hereafter described and figured; these are built in different ways, according to the fancy of the contriver. Some persons build them with upright glasses in front, about four feet high,

high, so that there is just height enough for persons to walk upright on the back-side of the bark-bed. Others make but one slope of glasses, from the top of the stove down to the plate, which lies about six or eight inches above the bark-pit, so that in the front of this stove, there is no walk made between the bark-pit and the glasses; but the inconveniency of watering the plants, as also of coming near those plants which are placed in the front of the stove to clean them, has, in some measure, brought them into disesteem, so that few persons now build them, tho' the expence is much less than of the other kind of stoves; but of both these stoves the figures and descriptions which are hereafter exhibited under the article of stove, will be sufficient for any person to build either of the sorts. One of these stoves about thirty-five feet long in the clear, with the pit or the tan reaching from end to end, and six feet and a half wide, will contain about fourscore fruiting plants; so that whoever is desirous to have this fruit, may easily proportion their stove to the quantity of fruit which they are willing to have.

But it will be also necessary to have a bark-pit under a deep frame, in order to raise the young plants; in which you should plunge the suckers, when they are taken from the old plants, as also the crowns which come from the fruit, so that this frame will be as a nursery to raise the young plants to supply the stove: but these plants should not remain in these frames longer than till the beginning of November, unless the frame is built with brick-work with flues in it to warm the air (in the manner hereafter described and figured), which are very useful, as nurseries, to keep the young plants till they are of a proper size to produce fruit; so that you may keep these either warmer or cooler than the stove, according as the plants may require, so that the stove may be every autumn filled only with bearing plants, whereby a much greater quantity of fruit may be annually produced, than can be where young and old plants must be crowded into the same stove. But where there are no conveniences of this kind, the young plants, about the middle or latter end of October, must be removed into the stove, and being small, may be crowded in among the larger plants; for as they will not grow much during the winter season, they may be placed very close together. The beginning of March, where there is no nursery for the young plants, they must be removed out into the hot-bed again, which should be prepared a fortnight before, that the tan may have acquired a proper heat: but you should be careful that the tan be not too hot, for that might scald the fibres of the plants, if they are suddenly plunged therein. Therefore if you find the bark too hot, you should not plunge the pots above two or three inches into the tan, letting them remain so until the heat of the tan is a little abated, when you should plunge the pots down to their rims in the bed. If the nights should continue cold after these plants are removed into the bed, you must carefully cover the glasses with mats; otherwise by coming out of a warm stove, they may receive a sudden check, which will greatly retard their growth, therefore must be carefully avoided; because the sooner the plants are set growing in the spring, the more time they will have to gain strength, in order to produce large fruit the following season.

You should not plunge the pots too close together in this frame, but allow them a proper distance, that the lower part of the plants may increase in bulk, for it is on this that the magnitude of the fruit depends; because when the plants are placed too close, they draw up very tall, but do not obtain strength; so that when they are taken out of the bed, the leaves are not able to support themselves; but all the outward long leaves will fall down, leaving the smaller middle leaves naked, and this sometimes will cause them to rot in the center. You must also observe, when the sun is very warm, to raise the glasses of the hot-bed, in order to let out the steam of the bed, and to admit fresh air; for one neglect of this kind, in a very hot

day, may destroy all the plants, or at least so scald them, that they will not get over it in several months. It will be also very proper, in extreme hot weather, to shade the glasses in the middle of the day with mats; for the glasses, lying so near to the leaves of the plants, will occasion a prodigious heat at such times. During the summer season these plants must be frequently watered, giving them but little each time; and in hot weather, they must have free air admitted to them every day, from ten o'clock till four; for if they are kept too close, or have too much wet, they will receive a check in their growth, when the insects will immediately spread over them; for there are generally some of these insects on all these plants, which do not much injury to them while they are in a growing state; but whenever they are unhealthy, the insects multiply greatly, and contribute to their decay. There are some persons who regulate the heat of their stoves by thermometers in summer, but at that season this is unnecessary, for the outward air in hot weather is frequently greater than the Ananas heat marked on the thermometers, so that the heat of the stoves at that season will be much greater. The use of the thermometer is only in the winter, during the time the fires are continued, by which it is easy to judge when to increase or diminish the fires; for at that season, the stoves should not be kept to a greater warmth than five or six divisions above Ananas, nor suffered to be more than as many divisions below it. In winter the plants must have less water, but they will require to have it repeated once a week, giving them but little each time: when the plants are placed into the tan for the winter season (which should be done about the beginning of October) the tan-bed should be renewed, adding two thirds of new tan, to one third of the old. If this be well mixed, and the new tan is good, the bed will maintain a proper degree of warmth till February, at which time it will be proper to stir up the bed, and add a load or two of new tan, so as to raise the bed as much as it sunk since the autumn; this will give a fresh heat to the bed, and keep the plants growing; and as the fruit will now begin to appear, it will be absolutely necessary to keep the plants in a growing state, otherwise the fruit will not be large.

In April it will be proper to stir up the tan again, and if the bed has sunk since the last stirring, it will be proper to add some fresh tan to it; this will renew the warmth of the bed, and forward the fruit. At this time it will be proper to shift the young plants, which are designed to produce fruit the following year; the tan-bed into which these are plunged must be renewed, in order to forward their growth, that they may have strength enough in autumn to produce good fruit, for in this is the principal care required.

Those plants which shew their fruit early in February, will ripen about June; some sorts are at least a month or five weeks longer in ripening their fruit than others, from the time of the appearance of the fruit: but the season in which the fruit is in greatest perfection, is from the beginning of July, to the end of September; though in March, April, and October, I have frequently eaten this fruit in pretty good perfection; but then the plants have been in perfect health, otherwise they seldom are well flavoured.

The method of judging when the fruit is ripe, is by the smell, and from observation; for as the several sorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor should they remain so long as to become soft to the touch before they are cut, for then they become flat and dead, as they do also when they are cut long before they are eaten, therefore the surest way to have this fruit in perfection, is to cut it the same day it is eaten; but it must be cut early in the morning, before the sun has heated the fruit, otherwise it will be hot, observing to cut the stalk as long to the fruit as possible, and lay it in a cool, but dry place, preserving the stalk and crown unto it, until it is eaten.

That sort with green fruit, if suffered to ripen well, is of an Olive colour; but there are some persons who cut them before they are ripe, when they are not fit to be eaten, for no other reason but to have them green: and although many persons have much recommended this sort for its excellent flavour, yet I think the Sugar-loaf sort is much to be preferred to it.

This Sugar-loaf sort is easily distinguished from all the other, by its leaves having purple stripes on their inside the whole length. The fruit is of a paler colour than the others when ripe, inclining to a straw colour. This sort was brought from Brasil to Jamaica, where it is esteemed far beyond the other kinds.

The next in goodness to this, is what the inhabitants of the islands in America call the Montserrat Pine; the leaves of this are of a dark brown, inclining to purple on their inside; the protuberances of the fruit are longer and flatter than those of the common sort. I raised several plants of this sort from seeds which I received from the island of St. Thomas, where this fruit is in greater perfection than in any of the British islands.

As some of the fruit produce seeds in England, when the greater number have no appearance of any, I doubt not whether there are not some with male, and others with hermaphrodite flowers; because those fruit which have seeds, are remarkably different from the others, when cut through the cells in which the seeds are lodged, lying nearer to the center of the fruit than the abortive cells, which are chiefly close to the rind; but not having distinguished this difference till the fruit was cut, I had no opportunity of examining their flowers.

I have continued this title of Ananas to the genus, being the most generally known and used, lest by altering it, the practical gardeners should be rather confused than instructed: and I was the rather inclined to this, as Dr. Linnæus has mistaken the characters of the three genera, which he has joined in one. The different varieties are also enumerated, for the sake of those who cultivate the fruit, though they are not distinct species, but vary in their shape, colour, and flavour, the same as other fruits. Therefore, as this work is intended to instruct the practical gardener, the mentioning these varieties is more excusable here, than in those books which are only intended for the improvement of botany.

ANAPODOPHYLLON. See **PODOPHYLLUM**.

ANASTATICA, Rose of Jericho.

The CHARACTERS are,

It hath a four leaved empalement, which falls off; the flower has four petals placed crosswise, which spread open, whose tails are the length of the tube of the empalement, and six awl-shaped stamina, two of which are shorter than the other four, crowned with roundish summits, and a small bifid germen, supporting an awl-shaped style the length of the stamina, and is permanent, crowned by a beaded summit. The germen afterward becomes a short bilocular pod, having an awl-shaped partition placed obliquely to the pod, and is longer.

We have but one SPECIES of this genus in the English gardens, viz.

ANASTATICA (*Hierocuntica*) foliis obtusis, spicis axillaribus brevissimis, filiculis unguulatis spinosis. Lin. Sp. 895. *Rose of Jericho with obtuse leaves, short spikes of flowers at the wings of the stalks, and prickly pods.*

This plant grows naturally in Palestine and Cairo, in sandy places near the sea. The stalks are ligneous though the plant is annual; it rises five or six inches high, dividing into many irregular branches; the flowers which are small and white, are disposed in short spikes at the wings of the stalks, and have little beauty; these are succeeded by short prickly pods, having two cells, in each of which are two seeds.

It is preserved in botanic gardens for the variety, and in some curious gardens for the oddness of the plant, which, if taken up before it is withered, and preserved entire in a dry room, may be long preserved; and after being many years kept in this situation, if the

root is placed in a glass of water a few hours, the buds of flowers will swell, open, and appear, as if newly taken out of the ground, to the great surprise of most people.

The plant is annual, so can only be propagated by seeds, which rarely ripen in England, unless the seeds are sown upon a hot-bed in the spring, and the plants afterward put into pots, which should be plunged into another hot-bed to bring them forward; for although the seeds will come up in the full ground where the soil is dry, yet the plants rarely rise to any size, nor do they perfect seeds unless the summer is very hot and dry: but if the plants are kept in a frame, giving them free air in warm weather, they will flower in June, and the seeds will ripen in September.

ANATOMY [*Anatōmía*, of *Anatōmō*, Gr. to dissect], a dissection.

Anatomy of plants is a cutting, dividing, or separating the parts or members of plants, in order to discover the size, form, structure, and uses of their several vessels, for the better promoting their culture.

Anatomists have observed a great similitude betwixt the mechanic frame of plants and animals: the parts of plants seeming to bear a constant analogy to those of animals; and the oeconomy, both vegetable and animal, seem to be formed on the same model.

The parts of a plant are the root, the wood, the bark, and the pith.

1. The roots of the plants are spongy bodies, whose parts are disposed for the easy admittance of certain humid particles, which are prepared in the ground. The quality of the root is found much to depend upon the size of its vessels and pores.

Monsieur Renaume supposes the root of a plant to do the office of all the parts in the abdomen of animals, which serve to nutrition, as the stomach, intestines, &c.

Dr. Boerhaave considers the roots of plants to be composed of a number of absorbent vessels, which are analogous to the lacteals in animals.

The root, according to Dr. Van Royen, is that part of the plant by which the nutriment is taken in, or that by which the aliment is attracted, as Theophrastus has defined it: but it is not all that part, which is committed to the earth, to be nourished by the matter which is about it, which is properly to be called the trunk of the root; this is to be referred rather to the stalk or stem, than to the root, in that it consists of the same implicated kinds of vessels; but that part which is by its surface contiguous to the exterior matrix, which, being perforated with infinite little mouths, promotes the received moistures, that they may be afterwards carried, by vessels not unlike to lacteal ones, into the very body of the plant; this is properly to be called the root.

Which definition, although it may seem too strict, is the most general, and applicable to all plants; for it agrees as well with them which have no root, as the vulgar opinion is, as to those which have a manifest root; of the former kind there are but very few plants, but of the latter a great many.

As to those that want a manifest root, the superficies of them is found to be perforated on all sides with very small holes, by which they take in their nutriment, as in the Pomo Aurantio, called Neptuni, or Pila Marina by fishermen, and many other submarine plants; and in these the whole superficies serves for roots, as is plainly seen in some stony plants that grow under the sea, and may be in some sort proved to be deduced from the analogy of animals; for these being become *sui generis*, take in aliment, not only by the mouth, but also the whole surface, exposed to the moist air, seems to serve to the same design. But although these submarine bodies have, by most naturalists, been ranged with vegetables; yet, by later discoveries, many of them have been found to consist of beds of insects, inclosed in small cavities of these incrustated bodies, therefore should rather be ranged with minerals.

But

But those plants that are endued with a conspicuous root, and more obvious to the senses, differ among themselves very much in this part: for some are bulbous, some are squamous, or tuberous, others grumous, others fibrous, and lastly, others nodous; which, as it will be sufficient to have taken notice of the primary differences of roots, I shall omit their particular definition in this place, and refer them to their several heads, where each of them shall be particularly described.

The first part of the root, which is called the Epidermis, or cuticle, is, for the most part, of a brown or dusky colour, very thin, and easily peeled off from the under skin (if it be first soaked in warm water); which being viewed by a microscope, shews its most tender structure much like a net pierced through with many small holes. And these little orifices of the epidermis being dilated, and filled with the received moisture, resembling vesicles, which, being exhausted yearly by the mutation of the air, become consolidated, and perish; to wit, this being driven out by a new cuticle growing under it, after the same manner as squammigerous animals annually cast the old epidermis, a new cuticle coming under it; so that these little vessels, fibrils, or by what name soever they are called, may not unfitly be compared to the veins of animals.

But the other part, which on the outside constitutes the cortex, or outer bark, and on the inside the liber, or inner bark, is called cutis; in which there are parts to be considered of a four-fold kind.

1. Certain strong fibres, cohering and elastic, stretched out vertically with the lateral fibres communicating among themselves, and compacting, or thrusting in the former, they form a hollow cylinder, or zone, under the epidermis; and this hath another under it, which also includes a third; and so of the rest, to the most inward of all, which luxuriates near the wood, and is by a peculiar name called liber, or inward bark. And these zones, or girdles, although they are most innumerable, may all be peeled off as the lamellæ of bulbs, when the sap flows through them; and inasmuch as those fibres in the harder roots of trees are almost of a bony nature, they procure a firmness to the cortex or outward bark; and these fibres are in all plants, and appear as well in grass as in the Cedar tree, although they are more compact in trees, than in plants of a tenderer structure, which are more easily sustained.

2. In the areas, or spaces, which are between the fibres and their anastomoses, there are every where membranaceous vessels full of moisture, or little utricles, which, in the areas, or intercepted spaces that are of a different figure, are found to be various, and accommodated to all the spaces; but all these utricles communicate among themselves, as is best seen in the greater celandine, when we squeeze out that golden coloured liquor with which it is filled; and the middle spaces betwixt these zones have like utricles, and all the fibres constitute hollow canals; but the utricles have receptacles communicating among themselves.

3. Aereal vessels, or tracheæ, are open from the lower to the upper part of the plant, and are twisted or curled after an admirable manner, and disposed round about with fibres and utricles in form almost of a spiral line, which in their cavities contain an elastic air; which being affected by the external air, first expanded, and afterwards condensed, will be changed after a like manner, and feel the same vicissitudes of cold and heat, and will undergo a reciprocal motion of cold and heat. This action is exerted in the vessels filled with moisture, which when they cannot be condensed, give place, and are driven to those that are higher, and are moved forward.

4. Lastly, besides fibres, utricles, and tracheæ, a peculiar kind of vessels appear, containing the moistures, as it seems secreted by the organical disposition of the plant itself, which water, or moisten not only the cortex, but the wood, and the rest of the

parts of vegetables, and are turgid with a concocted juice, which seems far more elaborate than is the moisture contained in the fibres or utricles; and the mouths of these vessels being of a different figure, pour forth sometimes a various liquor, according to its peculiar nature, chiefly near the outward region of the cortex; so the Tithymalus and Cichory commonly distil a milky humour, and the Cypress, Fir, and Pine, a certain species of turpentine.

And by how much these circles are more outward, by so much the middle spaces between the two zones are greater; and are lessened always towards the more inward in a certain proportion, which seems to depend on this, viz. the outward air acting on all sides with an equal pressure, and by a certain power presses the second; and this also by this means, is pressed by its own condensed air, and presses together those which are more inward, because it cannot exert its force upon the external air; therefore the second circle is necessarily more compressed than the first, and the third more than the second, and so of the rest. And the utricles placed between the circles are pressed by the same proportion; which, by degrees, are more and more exhausted; thence the inner circle loses most of all the compressed and condensed utricles, and by degrees grows solid.

And this is properly called Liber (the inward bark), and is that circle, which, being middlemost by place and nature, between the cortex, or outward bark, and the wood, comes nearest to the nature of the wood, and in time passes into it; for the cortex loses every year one such circle, and becomes wood, which may be distinguished from the former circles of the root, stock, or trunk; and if they are cut horizontally, will shew the number of such circles, and how many years the tree is old.

And this successive mutation of the cortex into liber, and of liber into wood, is like to that we observe in the human body in the beginning of a callus; for a callus consists of skin, but so compressed, that all the vessels are lost; and that skin, being become solid, is increased, and grows to a greater bulk. But besides these hitherto described, there occur certain peculiar vessels (of which mention has been made in describing the cortex), which are found full of turpentine, gum, or a certain concreted juice proper to them; the constant progress of which is not very conspicuous in all of them, by reason of the transparency of the moisture.

5. The fifth and last part is the most inward, the medulla or pith, disposed in the middle center of the root; and as it seems different from the former, seeing this is sometimes wasted, and that never, this appears more fungous, that more durable.

As to the manner of the root's performing its function, it may be observed, that the root having imbibed the saline and aqueous juices of the earth, and saturated itself with them, for the nourishment of the tree, those juices are put into motion by heat; which having entered the mouths of the arterial vessels from the root, they mount to the top with a force answerable to what sets them in motion; and, by this means, they gradually open the minute vessels rolled up, and expand them into leaves.

2. The wood; this is considered as consisting of capillary tubes, running parallel from the root throughout the stalk. Some call the capillary tubes arterial vessels, because the sap rises from the root through these. The aperture of these tubes are, for the most part, too minute to be perceived by the bare eye, unless in a piece of charcoal, cane, or the like.

Wood, says Dr. Græw, by microscopical observations, appears to be only an assemblage of infinitely minute canals, or hollow fibres, some of which arise from the root upwards, and are disposed in form of a circle; and the others, which are called insertions, tend horizontally from the surface to the center, so that they cross each other, and are interwoven like the threads of a weaver's web.

Besides

Besides the capillary tubes, &c. before-mentioned, there are other larger vessels, which some call venal vessels, which are disposed on the outside of the arterial vessels, between the wood and the inner bark, and lead down to the covering of the inward root. These vessels are supposed to contain the liquid sap found in plants in the spring, &c.

The Rev. Dr. Hales tells us in his excellent treatise on Vegetable Statics, that, in order to find whether there was any lateral communication of the sap and sap-vessels, as there is of the blood in animals, by means of the ramifications and lateral communications of their vessels; he took a young oak-branch, seven or eight inches diameter, at its transverse cut, six feet high, and full of leaves; and having cut a large gap to the pith, seven inches from the bottom, and of an equal depth the whole length, and also cut another gap four inches above that on the opposite side, he set the end of the stem in water, and in two nights and two days time it imbibed and perspired thirteen ounces; while another like oak-branch, somewhat bigger than that, but with no notches cut in its stem, imbibed twenty-five ounces.

From this and many other experiments he there mentions, he says, we see a most free lateral communication of the sap and sap-vessels, those great quantities of liquor having passed laterally by the gaps; in that, by several experiments on cylinders of wood, little evaporated by the gaps.

The bark is the exterior part of trees, serving them for a skin or covering: it is generally of a spongy texture, and communicates with the pith by a multiplicity of small fibres passing through the capillary tubes, of which the wood consists: so that the roots having imbibed the proper nutriment of the tree, it is carried up by the warmth of the sun, through the fine arterial vessel of the tree, to the top of it; and being there condensed by the cold, it does, by its own gravity, return down by the vessels which lie between the wood and the inner bark, which perform the office of veins; and as it passes by, leaves such parts of its juice as the texture of the bark will receive, and requires for its support.

Some are of opinion, that that soft whitish rind, or substance, which lies between the inner bark and the wood, does the office of veins: and some call this a third bark, and suppose it to differ from the other in nothing but having closer fibres, and that it contains the liquid sap, gums, &c. which are found in the plants in the spring and summer months, which hardens by degrees, by means of the sap it transmits, and is imperceptibly conveyed into the woody part of the tree.

The bark serves for divers purposes; for it not only transmits the nutritious juices of the plants, but also contains divers fat oily humours, to defend the inner parts from the injuries of the weather. As animals are furnished with a panniculus adiposus, usually replete with fat, which invests and covers all the fleshy parts, and screens them from external cold; so are plants encompassed with a bark, replete with fat juices, by means whereof the cold is kept out, and, in winter-time, the spiculæ of ice prevented from fixing and freezing the juices in their vessels; whence it is, that some sorts of trees remain ever-green throughout the year, by reason their barks are more compact, and contain a larger quantity of oil than can be spent and exhaled by the sun.

The pith is the inward central part of a tree or plant, answering to the medulla, or marrow of an animal. As for its substance, it consists of little transparent globules, chained or linked together, somewhat like the bubbles that compose the froth of liquor.

Some suppose, that the circulation of the sap is effected by means of the pith, others by the bark, and others by the wood.

Borelli, in his book *De Motu Animalium*, supposes the tender growing shoot to be distended like soft wax, by the expansion of the moisture in the spongy pith; which dilating moisture, he concludes, is hindered

from returning back, while it expands by the sponginess of the pith without the help of valves.

And the Rev. Dr. Hales is of opinion, that it is very probable, that the particles of water that immediately adhere to, and are strongly imbibed into, and attracted by, every fibre of the spongy pith, will suffer some degree of expansion before they can be detached by the warmth of the sun from each attracting fibre; and, consequently, the mass of spongy fibres, of which the pith consists, must therefore be extended.

And that the pith may be the more serviceable for this purpose, nature has provided in most shoots a strong partition at every knot, which partitions serve not only as plinths or abutments for the dilating pith to exert its force on, but also to prevent the too free retreat of the rarefied sap from the pith.

But a dilating spongy substance, by equally expanding itself every way, would not produce an oblong shoot, but rather a globous one, like an apple; to prevent which inconvenience it is observable, that nature has provided several diaphragms, besides those at each knot, which are placed at small distances across the pith, thereby preventing its too great lateral dilatation.

These are very plain to be seen in the shoots of the Walnut-tree, and the same may be observed in the pith of the branches of the Sun-flower, and several other plants, where those diaphragms are not to be distinguished while the pith is full and replete with moisture; yet when it dries up, they are often plain to be seen. And it is farther to be observed, that where the pith consists of distinct vesicles, the fibres of those vesicles are often found to run horizontally, whereby they can the better resist the too great lateral relaxation of the root.

The trunk and branches of a tree, bear a resemblance to the exterior members and limbs of an animal, which it may subsist without, though the rotting and mortification of them oftentimes occasion a total destruction of it. Accordingly the like effects are found from the wounding or lopping of a tree, as from the wounding or cutting off a limb, an extravasation, callosus, or the like.

A leaf is part of a plant extended into length and breadth in such a manner; as to have one side distinguishable from the other. The leaves, according to Malpighius, consist of so many interwoven utricles, as to be not much unlike a pulmonary net, and serve instead of lungs to the plant. As the perspiration and respiration are chiefly performed thereby, those vessels are very conspicuous when the leaves are dissected. In the day-time, when the heat hath rarefied the mounting juices, so as to become specifically lighter than the air, they flow out through the pores of the leaves, and evaporate, which is the occasion of the leaves becoming so flaccid in very hot weather; but in the night, when by the cold the juices are more condensed, then the leaves are erected again, and draw in a great share of nourishment from the air. These leaves we may observe to be of different textures on each side, the upper surface being for the most part smooth, the better to shoot off the redundant moisture, while the under surface is many times of a rough and cottony texture, by which it is capable of retaining the moisture; for which reason we find, if by bad management, &c. the shoots of trees are nailed to a wall, &c. so as to turn the surfaces of the leaves the wrong side upwards, the shoots will be at a stand, until the leaves have obtained their proper disposition. These leaves, as the learned Dr. Hales observes, are carefully distributed at small distances throughout the whole length of the shoots, and serve as so many jointly-acting powers, placed at different stations, thereby with more ease to draw plenty of sap to the extending root.

A flower is the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the rudiment of the fruit, and contains the organs of generation; some of these flowers contain the male organs, as the stamina and apices, which are loaded

with the farina fecundans; which, when ripe, is scattered into those flowers which are female, and consist only of the ovarium, with the style and stigma, which are surrounded with the petals. Other flowers there are, which have both sexes contained in the same flower; these are called hermaphrodite flowers.

A fruit, *Καρπός*, is not that part of a plant which is eatable, but rather the seeds, with their covering, should be called the fruit. This covering cherishes the seeds until they come to maturity, and defends them from the injuries of the weather, as that they are not hurt thereby; and also prepares the juices designed for their nourishment, that it may with ease enter their small bodies in a just proportion.

The motion of the nutritious juices of plants is produced much like that of the blood in animals, by the action of the air; and, in effect, there seems to be something equivalent to respiration throughout the whole plant.

Malpighius was the first who observed, that vegetables consisted of two series, or orders, of vessels.

1. Those which have been treated of before, which receive and convey the alimental juices, and which answer to the arteries, lacteal vessels, veins, &c. of animals; and,

2. The tracheæ, or air-vessels, which are long hollow pipes, in which the air is continually received and expelled, i. e. inspired and expired, within which tracheæ all the former vessels are contained.

Hence it follows, that the heat of the year, nay, of a single day, hour, or minute, must have an effect on the air included in these tracheæ, i. e. it must rarefy it, and, of consequence, dilate the tracheæ; and hence also a perpetual spring or source of action must arise, to promote the motion of the sap in plants.

For when the tracheæ are expanded, the vessels which contain the juices, are, by that expansion, pressed; and, by that means, the juice contained is continually propelled and accelerated; and, by this propulsion, the juice is continually comminuted, and rendered more and more subtil, and adapted to enter into vessels still finer and finer; the thickest part of it being at the same time secreted, and deposited into the lateral cells, or loculi of the bark, to defend the plant from cold, and other external injuries.

The vessels, or containing parts of plants, consist of mere earth, bound or connected together by oil, as a gluten, or glue; which being exhausted by fire, air, age, or the like, the plant moulders, or returns again into its earth or dust.

Thus vegetables being burnt by the most intense fire, the matter of the vessels is left entire and indissoluble, notwithstanding its utmost force; and, of consequence, is neither water, nor air, nor salt, nor sulphur, but earth alone.

Juice is a liquid substance, which makes part of the composition of plants, and communicates itself to all the other parts, and serves to feed and increase them; and is that to plants that blood is to animals. These juices are of divers sorts; aqueous, grumous, bituminous, oleaginous, resinous, vinous; of all tastes and colours.

This juice or sap of plants, is a humour furnished by the earth, and changed in the plant; it consists of some fossil, or other parts, which are derived from the air or rain; and others, from putrefied animals, plants, &c. so that, consequently, in vegetables are contained all kinds of salts, oil, water, earth, and, probably, all kinds of metals too, inasmuch as the ashes of vegetables always yield somewhat which is attracted by the load-stone.

The juice enters plants in the form of a fine subtil water, which by how much the nearer it is to the root, so much the more it retains of its proper nature; and the farther it is from the root, the more action it has undergone, and approaches the nearer to the nature of the vegetable; and, of consequence, when the juice enters the root, the bark of which is furnished with excretory vessels, fitted to discharge the excre-

mentitious part, it is earthy, watry, poor, acid, and scarce oily at all.

It is further prepared in the trunk and branches, though it continue acid still; as is perceived by the tapping or perforating of a tree in the month of February, when it distils a watry juice that is sensibly acid.

The juice being carried hence to the germs, or buds, is more connected; and when it has here unfolded the leaves, these come to serve as lungs for the circulation and further preparation of the juice; for when those tender leaves are exposed to the alternate action of heat and cold, moist nights, and hot scorching days, they are expanded and contracted alternately; and the more, by reason of their net-like texture.

By such means, the juice is farther altered and digested, as it is farther yet in the petala, or leaves of the flowers, which transmit the juice now brought to a further subtilty to the stamina; the stamina communicate it to the farina, or that dust which appears on the apices, where it undergoes a further maturation, and sheds into the pistil; and there acquiring its last perfection, it becomes the original of a new fruit or plant.

ANCHUSA. Lin. Gen. 167. Buglossum. Tourn. Inst. R. H. 133. tab. 53.

The CHARACTERS are,

The empalement is oblong, taper, and permanent, cut into five acute segments which are erect. The flower is of one leaf, having a cylindrical tube the length of the empalement; at the brim it is cut into five upright segments, which spread open, but the chaps are closed, and have five prominent little scales. There are five short stamina in the chaps of the flower, which are crowned with oblong summits. In the bottom of the flower are situated four germen, having a slender style, crowned with an obtuse stigma. The germen afterward becomes four oblong blunt seeds shut up in the empalement.

Dr. Linnæus ranges this genus of plants in the first section of his fifth class of plants, entitled Pentandria Monogynia, the flowers having five stamina and a single style.

The SPECIES are,

1. ANCHUSA (*Officinalis*) foliis lanceolatis spicis imbricatis secundis. Hort. Cliff. 46. *Alkanet with spear-shaped leaves, and fruitful imbricated spikes, or greater Garden Bugloss.* Buglossum angustifolium majus. C. B. P. 256.
2. ANCHUSA (*Angustifolia*) racemis subnudis conjugatis. Prod. Leyd. 408. *Alkanet with conjugated half naked spikes.* Borago sylvestris perennis flore rufo kermesino. Zan. Hist. 49.
3. ANCHUSA (*Undulata*) strigosa foliis linearibus dentatis pedicellis bractea minoribus calycibus fructiferis inflatis. Læfl. Lin. Sp. Plant. 133. *Alkanet with narrow indented leaves, small foot-stalks to the branches, and a swelling empalement over the seeds.* Buglossum Lusitanicum echii folio undulato. Tourn. Inst. 134.
4. ANCHUSA (*Orientalis*) villosa-tomentosa, ramis floribusque alternis axillaribus, bracteis ovatis. Lin. Sp. 191. *Alkanet with branches and flowers growing alternately from the wings of the stalks, and oval bractea or floral leaves.* Buglossum Orientale flore luteo. Tourn. Cor. 6.
5. ANCHUSA (*Virginiana*) floribus sparsis caule glabro. Lin. Sp. Plant. 133. *Alkanet with flowers growing thinly, and a smooth stalk.* Anchusa minor lutea Virginiana Puccoon indigena dicta quâ se pingunt Americani. Pluk. Alm. 30. *Called by the inhabitants of Virginia, Puccoon.*
6. ANCHUSA (*Sempervirens*) pedunculis diphyllis capitatis. Lin. Sp. Plant. 134. *Alkanet with foot-stalks having two leaves.* Buglossum latifolium sempervirens. C. B. P.
7. ANCHUSA (*Cretica*) foliis lanceolatis verrucosis semamplexicaulibus, floribus capitatis, caule procumbente. *Alkanet with warted and spear-shaped leaves embracing the stalk half round, flowers growing in a bead, and a trailing stalk.* Buglossum Creticum verrucosum perlatum quibusdam. H. R. Par.

O

8. ANCHUSA

8. *ANCHUSA* (*Tindoria*) *tomentosa*, foliis lanceolatis obtusis, staminibus corolla brevioribus. Lin. Sp. 192. *Anchusa with woolly, spear-shaped, blunt leaves, and the stamina of the flower shorter than the corolla, or true Alkanet of the shops.*

9. *ANCHUSA* (*Azurea*) foliis longis hirsutis, floribus capitatis reflexis, pedunculis longissimis. *Alkanet with long hairy leaves, and flowers collected into heads which are reflexed, and very long foot-stalks.* Borago sylvestre Cretica flore azureo. Zan. Hist. 51.

The first sort is the Bugloss, whose flowers are ordered to be used in medicine. This sends up stalks about two feet high, having oblong rough leaves, placed alternately, at the extremity of the shoots. The flowers are produced in clusters, which are of a fine blue colour; these come out with foot-stalks from the wings of the leaves, and are collected into small heads. The flowers are of one leaf, having a long tube, spread open at the top in shape of a funnel. After the flower is past, it is succeeded by four naked seeds, situated at the bottom of the empalement, which drop out as they ripen.

The roots of this sort seldom continue longer than two years, especially in good ground, for they are subject to rot in winter, unless when they happen to grow in rubbish, or out of an old wall, where they will live several years; for in such places the plants are stunted in their growth, so their branches are firmer and not so full of juice as those which grow in better soil. The plants may be easily propagated by seeds, which may be sown in the autumn, upon a bed of light sandy earth; and in the spring, when the plants are strong enough to remove, they should be planted in beds at two feet distance, observing, if the season proves dry, to water them till they have taken root, after which they will require no farther care but to keep them clean from weeds. If the seeds of this plant are permitted to scatter, the plants will rise in plenty, which may be managed in the manner before directed. There is a variety of this with white flowers, but this will not retain its difference from seeds.

The second sort grows to the height of two feet when cultivated in gardens, but in the places where it grows wild, is rarely more than a foot. The leaves of this are narrow, and less hairy than those of the first; the spikes of flowers come out double, and have no leaves about them; the flowers are small, and of a red colour. The roots will continue three or four years in poor land.

The third sort is a biennial plant, which perishes soon after the seeds are ripe. This grows two feet high, and sends out many lateral branches, which are garnished with long, narrow, rough leaves, which are waved on their edges: the flowers are of a bright blue colour, and grow in an imbricated spike; and after these fall, the empalement turns to a swollen vessel inclosing the seeds.

The fourth sort is a perennial plant, with long trailing branches which lie on the ground; the under leaves are long, broad, and hairy, but these diminish as they are nearer the top, and those which come out on the spikes between the flowers are short and roundish. The flowers are yellow, and about the size of those of the common Bugloss; there is a succession of these on the same plants great part of the year, which renders them more valuable. This, though a native of the Levant, is hardy enough to live in the open air in England, if it hath a dry sandy soil. It may be propagated by seeds in the same manner as the first sort, and if the seeds are permitted to scatter, the plants will rise without care.

The fifth sort is a native of North America, where it grows naturally in the woods, and being an early plant, generally flowers before the new leaves come out on the trees; so that in some of the woods, where this plant abounds, the surface of the ground seems covered with bright yellow flowers. It is known in that country by the title Puccoon. It is a perennial plant which seldom rises a foot high in good ground, but not above half that height, where the soil is poor; the

flowers grow in loose spikes, upon a smooth stalk. This is propagated by seeds, which, if sown in the spring, seldom grow the first year.

The sixth sort is a very hardy perennial plant, with weak trailing branches, garnished with broad, rough, deep green leaves; the flowers are blue, and come out between the leaves on the spike, like the fourth sort; the plants frequently grow out of the joints of old walls, in those places where any of the plants have been near; for when the seeds are permitted to scatter, there will be an abundant supply of the plants. These flower great part of the year.

The seventh sort is a low, trailing, annual plant, whose branches seldom extend more than six inches; these lie on the surface of the ground, and are thinly set with spear-shaped, small, warted leaves, which half surround the stalk at their base. The flowers are small, of a bright blue colour, and are collected into small bunches at the extremity of the branches. The plants perish soon after their seeds are ripe, which if permitted to scatter, the plants will come up better than when they are sown. These do not bear transplanting, so should remain in the places where they come up.

The eighth sort rises near as high as the first, to which it bears great resemblance in its leaves and branches; but the leaves and branches are more woolly, and the stamina of the flowers are shorter than the corolla; the root also is red. This plant grows naturally in the south of France and Spain, but is equally hardy with the first species, and may be cultivated in the same manner.

The ninth sort is a perennial plant, with broad rough leaves, like those of the sixth; the branches grow more erect, and the flowers which are of a bright azure colour, are collected into spikes, coming out singly from between the leaves. This is a hardy plant, and may be propagated in the same manner as the former.

ANDRACHNE, Bastard Orpine.

The CHARACTERS are,

It hath male and female flowers on the same plant. The male flower hath a five-leaved empalement, which is equal and withers. The flower is composed of five slender leaves indented at the top, which are shorter than the empalement. At the bottom of each petal is situated an herbaceous nectarium, to which the five slender stamina are joined; these are crowned with single summits. The female flowers come out from the wings of the stalk near the male. These have a permanent five-leaved empalement, but no petals; there are five nectariums as in the male, and a globular germen supporting three slender styles which are bifid, crowned with a round stigma. The germen afterward turns to a three cornered globular capsule, having three cells, in each of which are lodged two triangular obtuse seeds.

The SPECIES are,

1. *ANDRACHNE* (*Telephioides*) *procumbens* herbacea. Lin. Sp. Plant. 1014. *Herbaceous trailing Andrachne.* *Telephioides Græcum humifusum* flore albo. Tourn. Cdr. 50.

2. *ANDRACHNE* (*Fruticosa*) *erecta* arborea. Osb. It. 228. *Shrubby tree-like Bastard Orpine.*

3. *ANDRACHNE* (*Arborea*) foliis ovatis obtusis, subtus incanis, caule arboreo. *Bastard Orpine with oval blunt leaves, hoary on their under side, and a tree-like stalk.*

The first sort is a low plant, whose branches trail upon the ground. The leaves are small, of an oval shape, smooth, and of a sea-green colour. It is found wild in some parts of Italy, and in the Archipelago, from whence Dr. Tournefort sent the seeds to the royal garden at Paris: but being a plant of no great beauty, it is seldom cultivated, except in botanic gardens for variety. If the seeds of this plant are sown on a moderate hot-bed in March, the plants will arise in about a month after, when they may be transplanted each into a small pot, and plunged into another very moderate hot-bed to bring the plants forward, but in mild weather they should have plenty of air admitted to them, and often refreshed with water: in June they will produce flowers, and the seeds will ripen in

August

August and September, soon after which the plants will decay.

The second sort grows naturally in China, and also at La Vera Cruz in New Spain, where it rises twelve or fourteen feet high; the branches are garnished with spear-shaped, pointed, smooth leaves, under which the foot-stalk of the flowers are produced; these are pretty long and hang downward: the flowers are small, of an herbaceous white colour, some of which are male, and others female, but when the latter are situated at too great distance from the former, there is rarely any seeds within their covers; though they seem very fair to sight, yet upon being opened there will no seeds be found in them; whereby several persons have been deceived, who have sown them, without raising a single plant.

The third sort was discovered by the late Dr. William Houston, growing naturally at Campeachy; this has a strong woody stem, which rises more than twenty feet high, sending out branches on every side, which are garnished with oval blunt leaves, hoary on their under-side, and having pretty deep furrows on their upper, placed alternately on the branches: the flowers I have not seen, for the plant which rose from the seeds in the physic garden did not produce any, tho' it grew upward of fourteen feet high; nor were there any flowers upon the trees at Campeachy, at the time Dr. Houston was there, the seeds being then ripe; of these the doctor sent many to Europe which appeared very fair, but on being opened, no kernels were found within them, so that but one plant was raised from all the seeds.

These two sorts are very tender plants, so that when good seeds can be obtained, they should be planted in pots, plunging them into a hot-bed of tanners bark, observing to water them as the earth becomes dry in the pots; and when the plants come up, and are fit to remove, they should be each planted in a small pot, plunged into a tan-bed, shading them until they have taken fresh root, after which they should have free air admitted to them in warm weather, but must be constantly kept in the bark-stove.

There is also another sort which I have raised from seeds, sent me from Jamaica; the whole form of the seeds agree with those of the third sort, as do also the plants, but the leaves are somewhat like those of the Laurel, but are much larger; this hath not as yet flowered in Europe.

ANDROMEDA. Lin. Gen. Plant. 485. We have no English name for this plant.

The CHARACTERS are,

The empalement is cut into five small acute segments; this is coloured and permanent. The flower is of one leaf, oval, bell-shaped, and divided into five parts at the brim, which are reflexed. It hath ten awl-shaped stamina, which are shorter than the petals to which they are fixed; these are crowned with nodding summits having two horns. In the center of the flower is situated a round germen, supporting a cylindrical style, which is longer than the stamina, and crowned with a blunt stigma. The germen afterward turns to a round pentagonal vessel having five cells, which are filled with small round seeds.

This genus of plants is ranged by Dr. Linnæus in the first division of his tenth class, entitled Decandria Monogynia, the flowers having ten stamina and one germen.

The SPECIES are,

1. **ANDROMEDA** (*Polifolia*) pedunculis aggregatis, corollis ovatis, foliis alternis lanceolatis revolutis. Lin. Sp. Plant. 393. *Andromeda with aggregate foot-stalks, oval petals, and spear-shaped leaves growing alternately.* Polifolia. Buxb. Act. 2. p. 345.
2. **ANDROMEDA** (*Mariana*) pedunculis aggregatis corollis cylindricis foliis alternis ovatis integerrimis. Lin. Sp. Plant. 393. *Andromeda with aggregate foot-stalks, cylindrical flowers, and oval entire leaves placed alternately.*
3. **ANDROMEDA** (*Paniculata*) racemis fecundis nudis paniculatis, corollis subcylindricis foliis alternis oblongis crenulatis. Lin. Sp. Plant. 394. *Andromeda with naked,*

fruitful, loose spikes, cylindrical flowers, and oblong crenated leaves placed alternately. Vitis idæa Americana, longiori mucronato & crenato folio, floribus urceolatis racemosis. Pluk. Alm. 391.

4. **ANDROMEDA** (*Arborea*) racemis fecundis nudis, corollis rotundo-ovatis. Lin. Sp. Plant. 394. *Andromeda with naked fruitful spikes, and oval roundish flowers.* Frutex foliis oblongis acuminatis floribus spicatis uno versu dispositis. Catesb. Carolin. 1. p. 71. *commonly called Sorrel-tree in Carolina.*

5. **ANDROMEDA** (*Caliculata*) racemis fecundis foliaceis corollis subcylindricis, foliis alternis lanceolatis obrusis punctatis. Lin. Sp. Plant. 394. *Andromeda with leafy fruitful spikes, cylindrical flowers, and obtuse spear-shaped leaves, with punctures placed alternately.* Chamædaphne. Buxb. Act. 1. p. 241.

The first sort is a low plant which grows naturally on bogs in the northern countries, but is with difficulty preserved in gardens; and having little beauty, is seldom cultivated except in botanic gardens. I received the seeds from Petersburg, which came up in the Chelsea garden, but did not continue more than one year.

The second sort grows naturally in North America: this is a low shrub, which sends out many woody stalks from the root, garnished with oval leaves placed alternately; the flowers are collected in small bunches: these are shaped like those of the Strawberry-tree, and are of an herbaceous colour. They appear in June and July, and sometimes are succeeded by fruit, which seldom ripen in England.

The third sort is also a native of North America. This shrub grows about four feet high, sending out several branches, which are clothed with oblong leaves placed alternately; the flowers grow in loose spikes from the ends of the branches; they are of the pitcher shape, like those of the Arbutus, but are a little longer, and appear in July, but do not produce seeds in this country.

The fourth sort grows naturally in Virginia and Carolina; in the latter it is much larger than in the former, the climate being warmer; so many of the trees and shrubs grow to a much greater height there. In Virginia, it is a shrub growing ten or twelve feet high, but in Carolina it rises twenty feet. The branches are very slender, bending downward; these are garnished with leaves placed alternately, which are oblong and pointed: the flowers grow in long naked spikes, coming out from the sides of the branches, which are of an herbaceous colour, and are ranged on one side of the stalk; they are oval, and shaped like a pitcher.

The fifth sort grows naturally in Siberia, and also in North America; it is a low shrub which grows on mossy land, so is very difficult to keep in gardens. The leaves are shaped like those of the Box-tree, and are of the like consistence, having several small punctures on them; the flowers grow in short spikes from the extremity of the branches: these are produced single between two leaves, they are white and of a cylindrical pitcher shape.

All the sorts, except the fourth, are very hardy plants, which delight in moist ground; they increase by their creeping roots, which put up suckers at a distance, and may be taken off with roots, and transplanted where they are designed to remain, for they do not bear to be often removed.

The fourth sort requires to be sheltered from hard frost in winter, but in the summer should be frequently watered. It is a difficult plant to keep in gardens, as it grows naturally on boggy places, and requires a greater heat than that of this climate. It may be propagated by seeds, which should be procured from America, where it is known by the name of Sorrel-tree.

ANDROSACE. We have no English name for this plant.

The CHARACTERS are,

The flowers grow in an umbel; they have a many-leaved general involucre. Each flower hath a five-cornered empalement

A N D

palement of one leaf, slightly indented at the top in five acute points, this is permanent: the flower is of one leaf, having an oval tube, inclosed by the empalement, but is plain at the brim, where it is divided into five parts. It hath five small stamina within the tube, which are crowned with oblong erect summits. In the center is situated a round germen, supporting a short slender style, crowned by a globular stigma; the empalement afterward becomes a round capsule of one cell opening in five parts, which is full of round seeds.

Dr. Linnæus ranges this genus of plants in the first section of his fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. ANDROSACE (*Maxima*) perianthiis fructuum maximis. Hort. Uptal. 36. *Androsace with the largest empalement to the fruit.* Androsace vulgaris latifolia annua. Tourn. Inst. R. H. 123.
2. ANDROSACE (*Septentrionalis*) foliis lanceolatis dentatis glabris perianthiis angulatis corollâ brevioribus. Flor. Suec. 160. *Androsace with smooth, indented, spear-shaped leaves, and an angular empalement shorter than the petals.* Alfine verna Androsaces capitulis. C. B. P. 251.
3. ANDROSACE (*Villosa*) foliis pilosis perianthiis hirsutis. Lin. Sp. Plant. 142. *Androsace with hairy leaves and empalement.* Sedum Alpinum hirsutum lacteo flore. C. B. P. 284.
4. ANDROSACE (*Carnea*) foliis subulatis glabris, umbella involucrum æquante. Lin. Sp. 204. *Androsace with smooth awl-shaped leaves, and the umbel of flowers equal to the involucrum.*
5. ANDROSACE (*Lactea*) foliis linearibus glabris, umbellâ involucris multoties longiore. Lin. Sp. Plant. 142. *Androsace with narrow smooth leaves, and the umbel much longer than the involucrum.* Androsace Alpina perennis angustifolia glabra flore singulari. Tourn. Inst. R. H.

The first sort grows naturally in Austria and Bohemia amongst the corn: this hath broad leaves which spread near the ground, from the center of these the foot-stalks arise, which are terminated by the umbel of flowers, like those of the Auricula; under the umbel of flowers is a large empalement, which is permanent; the flowers are composed of five small white petals; these appear in April and May, the seeds ripen in June, and the plants soon after perish.

The other sorts are much smaller than this, some of them seldom growing more than three inches high, having very small flowers, so make little appearance. They grow naturally on the Alps and Helvetian mountains, as also in Siberia, from whence I have received the seeds of three or four species. These are only preserved in botanic gardens for the sake of variety, and all the sorts except the first should have a shady situation.

The seeds of all the sorts should be sown soon after they are ripe, otherwise they seldom grow the same year. They flower usually the beginning of April, and their seeds are ripe the end of May; which, if permitted to scatter, will come up, and often succeed better than those which are sown. The annual sorts perish as soon as the seeds are ripe, but the others will live in an open border for several years, and require no other care, but to keep them clean from weeds.

ANDROSÆMUM. See HYPERICUM.

ANDRYALA. Lin. Gen. Plant. 820. Downy Sowthistle.

The CHARACTERS are,

It hath a short, round, hairy empalement, cut into many equal segments; the flowers are composed of many hermaphrodite florets of one leaf, which are uniform, and lie over each other, stretched out like a tongue on one side. There are five stamina in the flowers; these are crowned by cylindrical summits, which are tubulous. The germen is situated at the bottom of each floret, with a slender style, crowned by two reflexed stigma. The germen afterward becomes a single oval seed, crowned with down.

This genus of plants is by Dr. Linnæus ranged in the first section of his nineteenth class, entitled Syn-

A N E

genesia Polygamia equalis, there being many hermaphrodite flowers included in one common empalement.

The SPECIES are,

1. ANDRYALA (*Integrifolia*) foliis integris ovato oblongis tomentosis. Guett. Stamp. 2. p. 384. *Downy Sowthistle with oval, oblong, entire, downy leaves.* Sonchus lanatus. Dalech. Hist. 1116.
2. ANDRYALA (*Ragulina*) foliis lanceolatis indivisis denticulatis acutis tomentosis, floribus solitariis. Lin. Sp. Plant. 1136. *Downy Sowthistle with indented, spear-shaped, woolly leaves.* Sonchus villosus luteus minor. C. B. P. 124.
3. ANDRYALA (*Sinuata*) foliis runcinatis. Lin. Sp. 1137. *Downy Sowthistle with plain-shaped leaves.*
4. ANDRYALA (*Lanata*) foliis oblongo-ovatis subdentatis lanatis, pedunculis ramosis. Amœn. Acad. 4. p. 288. *Downy Sowthistle with woolly, oblong, oval leaves, and branching foot-stalks.* Hieracium montanum tomentosum. Hort. Elth. tab. 150.

The first is an annual plant, which grows naturally in the south of France, Spain, and Italy, and is preserved in botanic gardens for the sake of variety. This grows a foot and a half high, with woolly branching stalks, having leaves scatteringly set on them, which are oblong and downy. The flowers are produced in small clusters at the top of the stalks, which are yellow, and like those of the Sowthistle, so do not make any great appearance. It is easily raised by seeds, which should be sown in the spring, in the place where the plants are to remain, and will require no other culture but to thin them where they are too close, and keep them clean from weeds. It flowers in July, and the seeds ripen in September.

The second is a perennial plant, which grows naturally in Spain, from whence I received the seeds, as I have also from the Cape of Good Hope. The leaves of this plant are extremely white, and are much indented on their edges; the flower-stalks grow about a foot high, having small clusters of yellow flowers, which appear in July; the seeds sometimes ripen in England, but not every year. The roots creep, by which the plants may be propagated. They love a light dry soil, in which they will live in the open air in this country.

The third sort grows naturally in Sicily, and also near Montpellier; the lower leaves of this sort are indented and woolly, but those upon the stalks are entire; this seldom rises more than a foot high, supporting a few yellow flowers at the top.

The fourth sort grows in Spain and Portugal; the leaves of this are broader, longer, and more downy, than either of the other sorts, the flower-stalks rise more than a foot high, branching into several foot-stalks, each sustaining one large yellow flower, shaped like those of Hawkweed, which are succeeded by oblong black seeds crowned with down.

These two plants are propagated by seeds, in the same manner as the former, which should be sown in autumn, for when they are sown in the spring, the plants seldom rise the same year.

A N E M O N E [*ἄνεμων*, of *ἀνέμω*, Gr. the wind; so called, because the flower is supposed not to open, except the wind blows.] Wind-flower.

The CHARACTERS are,

The flower is naked having no empalement, and consists of two or three orders of leaves or petals, which are oblong, and disposed in three series over each other. It hath a great number of slender stamina which are shorter than the petals, and are crowned by double summits which are erect; between these are situated many germen, which are collected into a head, supporting a pointed style crowned with a blunt stigma. The germen afterward become so many seeds inclosed with a down which adheres to the foot-stalk, and forms an obtuse cone.

Dr. Linnæus ranges this genus of plants in the sixth section of his thirteenth class, entitled Polyandria Polygynia, from the flowers having many stamina and germen.

The

The SPECIES are,

1. ANEMONE (*Sylvestris*) pedunculo nudo seminibus subrotundis hirsutis. Lin. Sp. Plant. 540. *Anemone with a naked stalk and a round head of hairy seeds.* Anemone sylvestris alba major. C. B. P. 176.
2. ANEMONE (*Nemorosa*) seminibus acutis foliolis incisis caule unifloro. Hort. Cliff. 224. *Anemone with pointed seeds, cut leaves, and a single flower.* Anemone nemorosa flore majore. C. B. P. 176.
3. ANEMONE (*Apennina*) seminibus acutis foliolis incisis petalis lanceolatis numerosis. Lin. Sp. Plant. 541. *Anemone with pointed seeds, cut leaves, and many spear-shaped flower leaves.* Ranunculus nemorosus flore purpureo-ceruleo. Park. Theat. 325.
4. ANEMONE (*Virginiana*) pedunculis alternis longissimis fructibus cylindricis seminibus hirsutis muticis. Lin. Sp. Plant. 540. *Anemone with very long alternate foot-stalks, and cylindrical spikes of chaffy seeds.* Anemone Virginiana tertiæ Matthioli similis flore parvo. H. L. 645.
5. ANEMONE (*Coronaria*) foliis radicalibus ternato-decompositis, involucro folioso. Lin. Sp. Plant. 539. *Anemone with lower leaves decomposed, and a leafy involucre.* Anemone tenuifolia simplici flore. C. B. P. 174.
6. ANEMONE (*Hortensis*) foliis digitatis. Lin. Sp. Plant. 540. *Anemone with hand-shaped leaves.* Anemone hortensis latifolia. 3 Clus. Hist. 1. p. 249.
7. ANEMONE (*Dichotoma*) caule dichotoma, foliis sessilibus oppositis amplexicaulibus trifidis incisis. Amæn. Acad. 1. p. 155. *Anemone with a forked stalk, and trifid cut leaves growing opposite, which embrace the stalks.*
8. ANEMONE (*Thalictroides*) foliis caulinis simplicibus verticillatis, radicalibus duplicato ternatis. Lin. Sp. 763. *Anemone with simple leaves on the stalk, growing in whorles, and those at the root double ternate.*

The first sort grows naturally in many parts of Germany; this approaches near to our Wood Anemone, but the seeds of it are round and hairy; the flower is large and white, but having little beauty, is seldom planted in gardens.

The second sort grows wild in the woods in many parts of England, where it flowers in April and May, making a pretty appearance in those places where they are in plenty. The roots of this may be taken up when their leaves decay, and transplanted in wildernesses, where they will thrive and increase greatly, if they are not disturbed; and in the spring, before the trees are covered with leaves, they will have a very good effect, in covering of the ground and making a pleasing variety at that season.

The third sort is found growing naturally in some parts of England, but particularly at Wimbledon in Surry, in a wood near the mansion-house, in great plenty; but it is not certain that they were not originally planted there, as they are not found in any other place in that neighbourhood. This sort flowers at the same time with the former, and when intermixed with them, make a fine variety. This may be transplanted from the woods as the former.

There are of these two sorts, some with double flowers, which have been obtained from seeds. These make a finer appearance, and continue longer in flower than the single, but are only to be procured from the gardens, where they are cultivated. As these are only feminal varieties, I have not enumerated them with the others.

The fourth sort grows naturally in North America, from whence the seeds are frequently sent to England. This is a very hardy plant, and produces plenty of seeds in England, but having little beauty, scarce deserves a place in gardens, unless for the sake of variety.

The fifth and sixth sorts are natives of the east, from whence their roots were brought originally; but have been so greatly improved by culture, as to render them some of the chief ornaments to our gardens in the spring. The principal colours of these flowers are red, white, purple, and blue, and some are finely variegated with red, white, and purple. There are many intermediate shades of these colours; the flowers

are large and very double, and, when properly managed, are extremely beautiful. I shall therefore proceed to give ample directions for their culture, which, if duly observed, every person may have these flowers in perfection.

Take a quantity of fresh untried earth (from a common, or some other pasture land) that is of a light sandy loam, or hazel mould, observing not to take it above ten inches deep below the surface; and if the turf be taken with it the better, provided it hath time to rot thoroughly before it is used: mix this with a third part of rotten cow dung, and lay it in a heap, keeping it turned over at least once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of the free air: in doing this be careful to rake out all great stones, and break the clods (but by no means sift or screen the earth, which is found very hurtful to many sorts of roots); for when the earth is made very fine, upon the first great rains of winter or spring, the small particles thereof join closely together, and form one solid mass, so that the roots often perish for want of some small stones to keep the particles asunder, and make way for the tender fibres to draw nourishment for the support of the root.

This earth should be mixed twelve months before it is used, if possible; but if you are constrained to use it sooner, you must turn it over the oftener, to mellow and break the clods; and observe to rake out all the parts of the green sward, that are not quite rotten, before you use it, which would be prejudicial to your roots, if suffered to remain. The beginning of September is a proper season to prepare the beds for planting (which, if in a wet soil, should be raised with this sort of earth six or eight inches above the surface of the ground, laying at the bottom some of the rakings of your heap to drain off the moisture; but in a dry soil, three inches above the surface will be sufficient): this compost should be laid at least two feet and a half thick, and in the bottom there should be about four or five inches of rotten neats dung, or the rotten dung of an old Melon or Cucumber-bed, so that you must take out the former soil of the beds to make room for it.

And observe in preparing your beds, to lay them (if in a wet soil) a little round, to shoot off the water; but in a dry one, let it be nearer to a level; in wet land, where the beds are raised above the surface, it will be proper to fill up the paths between them in winter, either with rotten tan or dung, to prevent the frost from penetrating into the sides of the beds, which often destroy their roots. The earth should be laid in the beds at least a fortnight or three weeks before you plant the roots; that it may settle; and when you plant them, stir the upper part of the soil about six inches deep, with a spade; then rake it even and smooth, and with a stick draw lines each way of the bed at six inches distance, so that the whole may be in squares, that the roots may be planted regularly: then with your three fingers make a hole in the center of each square, about three inches deep, laying therein a root with the eye uppermost; and when you have finished your bed, with the head of a rake draw the earth smooth, so as to cover the crown of the roots about two inches.

The best season for planting these roots, if for forward flowers, is about the latter end of September; and for those of a middle season, any time in October; but observe to perform this work, if possible, at or near the time of some gentle showers; for if the roots are planted when the ground is perfectly dry, and there should no rain fall for three weeks or a month after, they will be very apt to grow mouldy upon the crown, and if they once get this distemper, they seldom come to good after.

You may also reserve some of your Anemone roots till after Christmas, before you plant them, lest by the severity of the winter your early planted roots should be destroyed, which sometimes happens in very hard winters, especially in those places where

they are not covered to protect them from frost: these late planted roots will flower a fortnight or three weeks after those which were planted in autumn; and many times blow equally as fair, especially if it prove a moist spring, or that care be taken to refresh them gently with water.

But then the increase of these roots will not be near so great as those of your first planting, provided they were not hurt in winter; and it is for this reason all those who make sale of these roots, are forward in planting; for although it may happen, by sharp pinching frosts in the spring, that their flowers are not so double and fair as those planted a little later, yet if they can preserve the green leaves of the plants from being injured, the roots will greatly increase in bulk; but in such gardens where these flowers are preserved with care, there is always provision made to cover them from the injuries of the weather, by arching the beds over with hoops, or frames of wood, and covering them with garden-mats or cloths, in frosty nights, and bad weather, especially in the spring of the year, when their buds begin to appear; for otherwise, if you plant the best and most double flowers, the black frosts and cutting winds in March will cause them to blow single, by destroying the thrum that is in the middle of the flower; and this many times hath occasioned many people who have bought the roots, to think they were cheated in the purchase of them, when it was wholly owing to their neglect of covering them, that their flowers were single.

In the beginning of April your first planted roots will begin to flower, which will continue for three weeks or more, according to the heat of the weather, or the care taken in covering them, during the heat of the day, with mats or cloths: after these are past flowering, the second planted sorts will come to succeed them, and these will be followed by those planted in the spring; so that you may have these beauties continued for near two months together, or sometimes longer, if the season prove favourable, or proper care is taken to shade them in the heat of the day.

The beginning of June, the leaves of your first blown roots will begin to decay; soon after which time you must take them out of the ground, clearing them from decayed stalks, and washing them, to take the earth clean from the root; then spread them on a mat in a dry shady place till they are perfectly dried, when you may put them up in bags, and hang them out of the reach of mice, or other vermin, which will destroy many of the roots if they can come at them.

Observe also to take up the latter planted roots as soon as their leaves decay; for if they are suffered to remain long after in the ground, and there should fall some showers of rain, they would soon put forth fresh fibres, and make new shoots, when it would be too late to remove them: at the time when you take up the roots, is the proper season for breaking or parting them, which may be done by separating those that you would choose to make all possible increase from, into as many parts as you can conveniently, provided each one of them have a good eye or bud; but those you intend to blow strong, should by no means be parted too small, which greatly weakens their flowering.

The principal colours in Anemonies are, white, red, blue, and purple; and these in some of them, are curiously intermixed; but the most prevailing colours amongst our English raised Anemonies, are white and red; though of late we have received from France great varieties of blues and purples, which are exceeding fine flowers, and being intermixed with the English flowers, make a fine variety: we should therefore observe, in planting the roots, to distribute the different colours, so as to make an agreeable mixture of each in every bed, which will greatly add to their beauty.

But since all the fine varieties of these flowers were first obtained from seeds; no good florist, that hath garden room, should neglect to sow them: in order to which, we should provide ourselves with a quantity

of good single (or what the gardeners call Poppy Anemonies) of the best colours, and such as have more leaves than common, and have other good properties; these should be planted early, that they may have strength to produce good seeds, which will be ripe in three weeks or a month's time, after the flowers are past; when you must carefully gather it, otherwise it will be blown away in a short time, it being inclosed in a downy substance. You must preserve this seed till the beginning of August, when you may either sow it in pots, tubs, or a well prepared bed of light earth: in the doing of it you must be careful not to let your seeds be in heaps, to avoid which is a thing little understood, and is what I have been informed of by the late Mr. Obadiah Lowe, gardener at Battersea; who for several years raised large quantities of these flowers from seeds. His manner was thus:

After having levelled his bed of earth, in which he intended to sow his seeds, he rubbed the seeds well between his hands, with a little dry sand, in order to make them separate the better; then he sowed them as regularly as possible over the bed; but as these seeds will still adhere closely together by their down, he took a strong hair brush, with which he gently swept over the whole bed, observing not to brush off the seeds; this brush will so separate the seeds, if carefully managed, as not to leave any entire lumps; then gently sift some light earth, about a quarter of an inch thick over the seeds; and, if it should prove hot dry weather, it will be advisable to lay some mats hollow upon the bed in the heat of the day, and now and then give them a little water; but this must be given gently, lest by hastily watering you wash the seeds out of the ground; but be sure to uncover the bed at all times when there are gentle showers, and every night, that the seeds may have the benefit of the dews; and as the heat of the weather decreases, you may begin to uncover your bed in the day time also.

In about ten weeks after sowing, the plants will begin to appear, if the season has proved favourable, or your care in management hath not been wanting, otherwise they many times remain a whole year in the ground. The first winter after their appearing above ground, they are subject to injuries from hard frosts, or too much wet, against both of which you must equally defend them; for the frost is very apt to loosen the earth, so that the young plants are often turned out of the ground, after which a small frost will destroy them; and too much wet often rots their tender roots, so that all your former trouble may be lost in a short time for want of care in this particular; nor do I know of any thing more destructive to these tender plants, than the cold black frosts and winds of February and March, from which you must be careful to defend them, by placing a low reed fence on the north and east sides of the bed, which may be moveable, and only fastened to a few stakes to support it for the present, and may be taken quite away as the season advances, or removed to the south and west sides of the bed, to screen it from the violence of the sun, which often impairs these plants when young.

As the spring advances, if the weather should prove dry, you must gently refresh them with water, which will greatly strengthen your roots; and when the green leaves are decayed, if your roots are not too thick to remain in the same bed another year, you must clear off all the weeds and decayed leaves from the bed, and sift a little more of the same prepared good earth, about a quarter of an inch thick over the surface, and observe to keep them clear from weeds during the summer season, and at Michaelmas repeat the same earthing; but as these roots so left in the ground, will come up early in the autumn, the beds should be carefully covered in frosty weather, otherwise their leaves will be injured, whereby the roots will be weakened, if not destroyed. If your roots succeed well, many of them will flower the second year, when you may select all such as you like, by marking them with a stick; but you should not destroy any of them until

A N E

until after the third year, when you have seen them blow strong, at which time you will be capable to judge of their goodness; for until the roots have acquired strength, the flowers will not shew themselves to advantage.

By this time your roots will be too thick in the seed-bed to remain, therefore you must, as soon as their green leaves are decayed, sift the earth of your bed through a very fine sieve, in order to get out the roots, which can be no otherwise found, as being small, and so nearly the colour of the ground; but in doing this, observe not to disturb the ground too deep, so as to endanger the burying any of the roots; for, notwithstanding all your care, many small roots will be left behind, therefore as soon as you have sifted your whole bed, and taken out all the roots you can find, you must level the earth of your bed again, and let it remain till next year, when you will find a plentiful crop of roots come up again; the young roots which you take up must be dried, as was directed for the old ones, but should be planted again three weeks before them, that they may increase in strength, so as to flower strongly the succeeding year.

The single (or Poppy) Anemonies will flower most part of the winter and spring, when the seasons are favourable, if they are planted in a warm situation, at which time they make a fine appearance, therefore deserve a place in every flower-garden, especially as they require little culture; for if these roots are taken up every other year, it will be often enough; and when they are taken up, they should be planted again very early in the autumn, otherwise they will not flower till the spring. There are some fine blue colours amongst these single Anemonies, which, with the Scarlets and Reds, make a beautiful mixture of colours; and as these begin flowering in January or February, when the weather is cold, they will continue a long time in beauty, provided the frost is not too severe. The seeds of these are ripe by the middle or end of May, and must be gathered daily as it ripens, otherwise it will soon be blown away by the winds.

The Anemone grows naturally in the Levant, particularly in the islands of the Archipelago, where the borders of the fields are covered with them of all the colours, but the flowers are single, and have been greatly improved by culture. In France they were long cultivated before they were much known in Holland or England. Tournefort mentions two French gentlemen, Messrs. Malaval and Bachelier, who contributed greatly to the improvement of these flowers; and of the latter he relates a pleasant story, as follows: There was a certain lawyer to whom Mr. Bachelier had refused to communicate the seeds of his fine Anemonies, and finding he could not obtain any either by friendship or money, a fancy came into his head, to make a visit to Mr. Bachelier, with some of his friends who were in the secret; he ordered his lacquey who supported the train of his gown, to let it drop on a bed where the Anemonies grew, which he wanted, whose seeds were then ripe. They walked a considerable time talking on various subjects, and when they came to the spot where the Anemonies grew, a merry gentleman of the company began a story, which engaged the attention of Mr. Bachelier; at which time the lacquey, who was no fool, let fall his master's train over the bed, and the seeds having a downy covering, stuck to the gown, which the boy afterwards took up again, and the company went forward. The virtuoso took leave of Mr. Bachelier, and went directly home, where he carefully picked off the seeds which had stuck to his robes, and sowed them, which produced very beautiful flowers.

The seventh sort grows naturally in Canada and Siberia; the roots of this creep and multiply greatly in the ground, the lower leaves are deeply cut; the stalks rise two feet high, garnished with leaves placed opposite, which embrace the stalks, and the flowers are produced from the forks of the stalks upon slender foot-stalks; these flowers are white, and being

A N G

small, make little appearance, so the plant is rarely preserved, except in botanic gardens for variety: it is a very hardy plant, and multiplies very fast where it is allowed to have a place.

The eighth sort is a very humble plant, seldom rising more than six inches high. This grows naturally in the woods of North America, where it flowers early in the spring, when it makes a pretty appearance, especially if many of the plants grow in clusters: some of these flowers are double, which make a better appearance than the single, and continue longer in beauty. The leaves of this plant are very like those of Meadow Rue; the stalks have leaves growing in whorles, and are terminated by a single flower: this sort should be planted under the shelter of trees, and if the surface of the ground is covered with rotten tanners bark in winter, it will greatly preserve the plants.

ANEMONOIDES. See **ANEMONE.**

ANEMONOSPERMOS. See **ARCTOTIS.**

ANETHUM, Dill, from *ἀν* and *θῆν*, to run up, because it is quick of growth.

The **CHARACTERS** are,

It is an umbelliferous plant, having many umbels, which have no involucre. The umbels are uniform, and composed of many smaller ones. The flowers have five spear-shaped petals, each of these have five slender stamina, crowned with blunt summits; under the flower is situated the germen, supporting two small styles crowned with blunt stigma; the germen afterward becomes two compressed seeds having borders.

This genus of plants is ranged in the second section of the fifth class of Linnæus's genera, which is entitled Pentandria Digynia, the flowers having five stamina and two styles.

We have but one **SPECIES** of this genus, viz.

ANETHUM (*Graveolens*) fructibus compressis. Hort. Cliff. 106. *Dill with compressed seeds.* Anethum hortense. C. B. P. 147. *Common Dill.*

There are two other varieties which are mentioned as distinct species by the botanists, but I have frequently sown them, and have always found them prove to be only varieties arising from the same seeds.

This plant is propagated by sowing the seeds, which should be done in autumn soon after they are ripe; for if they are kept out of the ground till spring, they frequently miscarry; or if any of the plants come up, they often decay before they have perfected their seeds. They love a light soil, and will not bear to be transplanted, but must be sown where they are to remain, and should be allowed eight or ten inches room to grow, otherwise they will draw up very weak, and produce few lateral branches, whereby their leaves will decay, and be rendered useless, nor will they produce so good seeds; therefore the best way is, when the plants are come up, to hoe them out, as is practised for Onions, Carrots, &c, leaving the plants about eight or ten inches asunder every way, observing to keep them clear from weeds; and when the seeds begin to be formed, you should cut up those that are intended to be put into the pickle for Cucumbers, leaving those that are intended for the use of the seeds until they are ripe; at which time it should be cut, and spread upon a cloth to dry, and then beat out for use: if you let the seeds fall upon the ground, the plants will rise the next spring without any care, so that the trouble of sowing their seeds may be spared.

ANGELICA [of *Angelus*, so called, as some quacks, &c. pretend, from the angels, on account of its excellent qualities.]

The **CHARACTERS** are,

It is an umbelliferous plant, the greater umbel being composed of many small ones; the involucre, or cover of the large umbel, is composed of five small leaves, and those of the smaller of eight, and the empalement of the flowers are indented in five parts. The flowers of the whole umbel are uniform, each of them consist of five petals which fall away; these have five stamina, which are longer than the petals, and are crowned with single summits. The

germen

germen is situated below the flower, supporting two reflexed styles, crowned with obtuse stigma; the germen afterward becomes a roundish fruit splitting into two, and composed of two seeds, which are plain on one side, convex on the other, and are bordered.

This genus of plants is ranged in the second section of Linnæus's fifth class, entitled Pentandria Digynia, from the flowers having five stamina and two styles.

The SPECIES are,

1. ANGELICA (*Sativa*) foliorum impari lobato. Flor. Lapp. 101. *Angelica with leaves composed of an unequal number of lobes.* Angelica sativa. C. B. P. 155. *Garden Angelica.*
2. ANGELICA (*Archangelica*) altissima foliorum lobatis maximis serratis. *Tallest Angelica with leaves composed of large serrated lobes.* Angelica scandiaca Archangelica. Tabern. Icon. 82.
3. ANGELICA (*Sylvestris*) foliis æqualibus ovato-lanceolatis serratis. Hort. Cliff. 97. *Angelica with equal leaves, composed of oval spear-shaped lobes which are sawed.* Angelica sylvestris major. C. B. P. 155.
4. ANGELICA (*Atropurpurea*) extimo foliorum pari coadunato folio terminali petiolato. Prod. Leyd. 103. *Angelica with the extreme pair of leaves joined, and terminated with a foot-stalk.* Angelica Canadensis atropurpurea. Cornut. Canad. 198.
5. ANGELICA (*Lucida*) foliis æqualibus ovatis inciso-serratis. Hort. Cliff. 97. *Angelica with equal leaves and oval lobes, which are cut and sawed.* Angelica lucida Canadensis. Cornut. Canad. 196.

The first sort is the common Angelica, which is cultivated in the gardens for medicinal use, as also for making a sweetmeat, which is by some greatly esteemed. This grows naturally by the side of rivers in northern countries.

The second sort grows naturally in Hungary, and some parts of Germany. This hath been supposed to be only a variety of the first by many modern botanists; but from many years experience in the culture of this plant, I could never observe any alteration in it; for all the plants which I raised from seeds, proved exactly the same as the parent plant, and when planted in the same soil with the common sort, they were twice their size. The leaves were also much larger, and deeper sawed on their edges, the umbels much larger, and the flowers were yellow. This sort seldom continues longer than two or three years, so that young plants should be raised to preserve the species. The seeds should be sown in autumn, for those which are sown in the spring seldom succeed.

The third sort grows naturally in moist meadows, and by the sides of rivers in many parts of England, so is seldom admitted into gardens.

The fourth and fifth sorts grow naturally in North America, from whence their seeds were sent to Europe, where the plants are preserved in gardens for the sake of variety; but as they have no use and but little beauty, they are not admitted into many gardens. They are both very hardy plants, and may be easily propagated by seeds, which should be sown in autumn, and when the plants are large enough to remove, they must be transplanted into a moist soil, and have a shady situation, allowing them two feet room on every side. They grow four or five feet high, and put out many shoots from the root, especially the second year from seed, when they will flower in June, and the seeds ripen in September. The roots of these sorts seldom continue longer than two or three years. The common Angelica delights to grow in a very moist soil; the seeds of this plant should be sown soon after they are ripe, for if they are kept until the spring, seldom one seed in forty will grow. When the plants are come up about six inches high, they should be transplanted at a large distance, for their leaves extend very wide; the best place for this plant is upon the sides of ditches, or pools of water; where being planted about three feet asunder, they will thrive exceedingly. The second year after sowing, they will shoot up to flower; therefore if you have a mind to continue their roots, you should cut down

these stems in May, which will occasion their putting out heads from the sides of the roots, whereby they may be continued for three or four years; whereas, if they had been permitted to seed, their roots would perish soon after.

The gardeners near London, who have ditches of water running through their gardens, propagate great quantities of this plant, for which they have a great demand from the confectioners, who make a sweetmeat with the tender stalks of it cut in May.

This plant is also used in medicine, as are also the seeds; therefore where it is cultivated for the seeds, there should be new plantations annually made to supply the places of those which die, for when they are permitted to seed, they last but two years.

ANGUINA. See TRICOSANTHES.

ANGURIA, the Water Melon, or Citrul.

The CHARACTERS are,

It hath male and female flowers growing at separate distances on the same plant; the flowers of both sexes are of the open bell-shaped kind, of one leaf, and have empalements of the same form. The male flowers have three short stamina, which are joined together at the top; these are crowned by slender summits. The female flowers rest upon an oval germen, supporting a cylindrical style, crowned by three large stigma, which are gibbous; the germen afterward becomes an oblong fleshy fruit, having five cells filled with compressed seeds, which are rounded at their extremity.

Dr. Linnæus joins this genus to the Gourd, but whoever will allow the fruit to be a characteristic in determining the genera, must keep them separate; for the Gourd hath but three cells, whereas the Anguria has five.

This genus is ranged in the tenth section of Linnæus's twenty-first class of plants, entitled Monœcia Syngenesia, from the flowers being male and female in the same plant, and the stamina and summits growing together.

We have but one SPECIES of this genus, viz.

ANGURIA foliis multipartitis. *Water Melon with leaves cut into many parts.* Anguria Citrullus dicta. C. B. P. 312. Of this there are several varieties which differ in the form and colour of their fruit; but as these vary annually from seeds, it is needless to enumerate them here. This fruit is cultivated in Spain, Portugal, Italy, and most other warm countries in Europe; as also in Africa, Asia, and America, and is by the inhabitants of those countries greatly esteemed for their wholesome cooling quality; but in England the fruit is not so universally esteemed, though some few persons are very fond of them. I shall therefore give full directions for raising them, so that such persons as are willing to be at the expence and trouble of it, may not be at a loss for instructions.

First provide some seeds, which should be three or four years old; for new seeds are apt to produce vigorous plants, which are seldom so fruitful as those of a moderate strength. The best sorts to cultivate in England, are those with small round fruit, which come from Astracan, those with very large fruit, seldom ripen well in this climate. Having provided good seed, you should prepare a heap of new dung the beginning of February, which should be thrown in a heap for about twelve days to heat, turning it over twice, mixing it well; then you should make a hot-bed, in which these seeds, as also Cucumber-seeds and Musk Melons may be sown. The dung should be well wrought in making the bed, and must be beaten down pretty close with a dung-fork, that the heat may not be too violent, and of longer continuance. When the dung is thus laid, you should cover it about four inches thick with good light earth, and having spread it very even, you should put the frame and glass over it, leaving it to warm four or five days before you put the seeds into it, observing, if the steam rises pretty much, to raise up the glass to let it pass off: then, if you find your bed in proper temper, you may sow your seeds therein in drills, covering them over with earth about half an inch. After this,

this, if you find your bed very warm, you must give air in the day-time by raising the glasses; but if the bed is cool, you must cover it well with mats every night, as also in bad weather. In four or five days after, you must prepare another hot-bed to receive these plants, which will be fit to transplant in ten days, or a fortnight at most, after the seeds are sown; this bed need not be very large, for a few of these plants will fill a large quantity of frames, when they are planted out for good, and while the plants are young, there may be a great quantity kept in one light; so that those persons who raise early Cucumbers and Musk Melons, may also raise these plants in the same bed; for two or three lights will be sufficient to raise plants of all three kinds, to supply the largest families, until they are planted out for good. In the management of these plants while young, there is little difference from the directions given for raising Musk Melons, therefore I need not repeat it here. The chief thing to be observed, is, to let them have a large share of air whenever the weather will permit, otherwise the plants will draw up weak, and be good for little. As these plants will require two or three hot-beds to bring the fruit to perfection, it will be the better way to put the plants into baskets, when they have gotten four leaves, as is directed for raising early Cucumbers; but you should not plant more than two plants in each basket, for if one of them lives it will be sufficient; therefore when both the plants succeed, you should draw out the weakest and most unpromising of them, before they begin to put out their side shoots, otherwise they will entangle and render it difficult to be performed, without greatly injuring the remaining plant.

The baskets in which these plants are to be planted, need not be more than a foot diameter; so that one light will contain eight of them, which will be sufficient for twenty-four lights, when they are planted out for good; for where the plants are vigorous, one single plant will spread so far as to fill three lights; and if they have not room, they seldom set their fruit well.

These baskets may remain in the nursery-beds until the plants have spread, and put out many runners; for when the heat of this bed declines, it is soon revived by adding a proper lining of warm dung to the sides of the bed quite round; so that when they are taken out of this bed, and placed in the ridges where they are to remain, the heat of the beds will last so long as to set their fruit, which is of great consequence; for when the plants are ridged out very young, the beds are generally made of great thickness in dung, in order to continue their heat; so that for some time after they are made, they are so extreme hot, as to endanger the scalding of the plants; and by the time the fruit begins to appear, there is little heat left in the beds, which often occasions the fruit to drop off, and come to nothing.

After these plants are placed in the beds where they are to remain, you must carefully lead the shoots as they are produced, so as to fill each part of the frame; but not to crowd each other; and be careful to keep them clear from weeds, as also to admit fresh air whenever the weather will permit; they must also be frequently watered, but do not give it them in great quantities. In short, there is little difference to be observed in the management of these, from that of Musk Melons, but only to give them more room, and to keep the beds to a good temperature of heat, and when the fruit appears, to admit air freely to the plants, in order to set their fruit; but when the nights are cold, the glasses must be covered with mats to keep the beds warm, without which this fruit will seldom come to good in this country.

ANIL. See INDIGOPHERA.

ANISUM, or ANISE. See PIMPINELLA.

ANNONA. Lin. Gen. Plant. 613. Guanabanus. Plum. Nov. Gen. 10. *The Custard Apple, &c.*

The CHARACTERS are,

The empalement is composed of three small heart-shaped

leaves, which are concave and pointed. The flower hath six petals, three large and three alternately smaller. The stamina is scarce discernible; but there are many summits on each side the germen, which is situated at the bottom of the flower, having no style, but an obtuse stigma. The germen afterward becomes an oval, or oblong fruit, having a scaly rind, and one cell, in which are lodged many oval smooth seeds.

This genus of plants is ranged in the seventh section of Linnæus's thirteenth class, entitled Polyandria Polyginia, the flowers of this division having many stamina and several germen.

The SPECIES are,

1. ANNONA (*Reticulata*) foliis lanceolatis fructibus ovatis reticulato-areolatis. Lin. Sp. Plant. 537. *Annona with spear-shaped leaves, and oval fruit which are netted, or wrought in squares. Guanabanus fructu aureo & mollior aculeato. Plum. Nov. Gen. 43. The Custard Apple.*
2. ANNONA (*Muricatis*) foliis ovali-lanceolatis glabris nitidis planis pomis muricatis. Hort. Cliff. 222. *Annona with plain, smooth, shining, oval, spear-shaped leaves, and a prickly fruit. Guanabanus fructu viridi lutescente mollior aculeato. Plum. Nov. Gen. 43. The Sour Sop.*
3. ANNONA (*Squamosa*) foliis oblongis fructibus obtusè subquatis. Lin. Sp. Plant. 537. *Annona with oblong leaves, and obtuse scaly fruit. Guanabanus foliis odoratis fructu subrotundo squamoso. Plum. Nov. Gen. 43. The Sweet Sop.*
4. ANNONA (*Palustris*) foliis oblongis obtusis glabris, fructu rotundo, cortice glabro. *Annona with oblong, blunt, smooth leaves, and round fruit, with a smooth skin. Guanabanus palustris fructu lævi viridi. Plum. Nov. The Water Apple.*
5. ANNONA (*Cherimola*) foliis latissimis glabris, fructu oblongo squamato, seminibus nitidissimis. *Annona with very broad smooth leaves, oblong scaly fruit, and very shining seeds.*
6. ANNONA (*Africana*) foliis ovato-lanceolatis pubescentibus fructu glabro subcæruleo. *Annona with oval, spear-shaped, downy leaves, and smooth bluish fruit. Guanabanus fructu subcæruleo. Plum. Nov. Gen. 43. The Sweet Apple.*
7. ANNONA (*Asiatica*) foliis lanceolatis glabris nitidis fecundum nervos sulcatis. Hort. Cliff. 222. *Annona with neat spear-shaped leaves, with nervous furrows. Guanabanus fructu purpureo. Plum. Nov. Gen. 43. The Purple Apple.*
8. ANNONA (*Triloba*) foliis lanceolatis fructibus trifidis. Lin. Sp. Plant. 537. *Annona with spear-shaped leaves, and trifid fruit. Annona fructu lutescente lævi ferorum arietis referente. Catech. Car. 2. 85. The North American Annona, called by the inhabitants Papaw.*

The first sort usually grows to the height of twenty-five feet, or upwards, in the West-Indies, and is well furnished with branches on every side; the bark is smooth, and of an Ash colour; the leaves are oblong, of a light green colour, and have several deep transverse ribs or veins, ending in acute points; the fruit is of a conical form, as large as a tennis-ball, of an Orange colour when ripe, having a soft, sweet, yellowish pulp, of the consistence of a custard, from whence the title of Custard Apple was given to it.

The second sort is not so large as the first, rarely rising above twenty feet high, and not so well furnished with branches; the leaves are broader than those, have a smooth surface without any furrows, and are of a shining green colour; the fruit is large, of an oval shape, irregular, and pointed at the top, being of a greenish yellow colour, and full of small knobs on the outside; the pulp is soft, white, and of a sour and sweet taste intermixed, having many oblong dark-coloured seeds.

The third sort is a tree of humbler growth, seldom rising more than fifteen feet high, and is well furnished with branches on every side; the leaves of this sort have an agreeable scent when rubbed; the fruit is roundish and scaly, and when ripe turns of a purple colour, and hath a sweet pulp.

Q

The

The fourth sort commonly grows from thirty to forty feet in the West-Indies. This hath oblong pointed leaves, which have some slender furrows, and when rubbed have a strong scent; the fruit of this sort is seldom eaten but by the negroes; the tree grows in moist places in all the islands of the West-Indies.

The fifth sort is much cultivated in Peru for the fruit, and from thence the seeds have been brought to England, and many plants have been raised. This grows to be a very large tree in the natural country of its growth, and is well furnished with branches, which are garnished with leaves of a bright green colour, which are much larger than those of any of the other sorts. The fruit is oblong and scaly on the outside, and of a dark purple colour when ripe; the flesh is soft and sweet, has many brown seeds intermixed, which are very smooth and shining; the fruit is esteemed by the Peruvians as one of their most delicate sorts. This has produced flowers in England, but no fruit.

The sixth and seventh sorts grow in some of the French islands, as also in Cuba, in great plenty; these grow to the height of thirty feet or more; their fruit are esteemed by the inhabitants of those islands, who frequently give them to sick persons, as they reckon them very cooling and wholesome.

The eighth sort grows plentifully in the Bahama islands, where it seldom rises to more than ten feet high, having several stems; the fruit of this sort are shaped like a Pear inverted. This is seldom eaten but by the negroes, and is the food of guanas, and other animals.

This sort will thrive in the open air in England, if it is planted in a warm sheltered situation; but the plants should be trained up in pots, and sheltered in winter for two or three years, until they have acquired some strength; then they may be turned out of the pots in the spring, and planted in the full ground, where they are to remain. This sort has produced flowers in the curious garden of his grace the duke of Argyle, at Whitton, near Hounslow, where it has been growing in the open air for some years, as also in the nursery of the late Mr. Gray, near Fulham. The seeds of this sort are frequently brought to England from North America, which are much larger than those of the other species, and many plants have been lately raised in the gardens near London. The shape of the leaves is also different; this casts its leaves in autumn, whereas all the others retain their leaves, never casting them until the spring, when the leaves come out. The fruit is very different from those of the other species, two or three growing together at their foot-stalks. When the seeds of this sort are sown, they frequently remain a whole year in the ground; therefore the earth in the pots should not be disturbed, where they are sown, if the plants do not come up the first year; and the pots should be sheltered in winter, and the following spring if they are plunged into a new hot-bed, the plants will come up much sooner than those which are sown in the open air, so will have more time to get strength before the winter.

All the other sorts which are natives of the warm parts of America, are too tender to live in this country, if they are not preserved in warm stoves; they come up very easily from the seeds which are brought from America, if they are fresh; but these seeds must be sown on a good hot-bed, or in pots of light earth, and plunged into a hot-bed of tanners bark in February, which is by much the best time; because when the plants come up early, they will have time to get strength before the cold weather comes on in the autumn.

These plants should be kept in the bark-stove, and carefully managed, with which they will make great progress; but in warm weather they should have plenty of fresh air admitted to them, for when the air is excluded from them too much, they are apt to grow sickly, and are often attacked by vermin, which will multiply and spread over the whole surface of the

leaves, and cause them to decay; but when carefully managed, their leaves will continue green all the winter, and make a very good appearance in the stove at that season.

As these plants advance in their growth, they should be shifted into larger pots; but this must be done with caution, for nothing is more prejudicial to them than over-potting them. They must also constantly remain in the tan-bed, otherwise they will make but little progress; for although they will live in a dry stove, yet they will make little progress, nor will their leaves appear so fine, as when they are preserved in a vigorous growing state; and it is more for the beauty of their leaves, than any hopes of their producing fruit in this country, that they are preserved in stoves: for though there has been some of the sorts which have produced flowers in England, yet none have ever shown their fruit here.

Some of these plants are twelve or fourteen feet high in our gardens, and a few years ago there were plants of the fifth sort in the garden at Chelsea, which were more than twenty feet high, and produced flowers two or three years. The stove in which these plants are placed, should, during the winter season, be kept to the Anapas heat, marked on the botanical thermometers. The earth should be light and rich in which they are planted, and the tan-bed should be frequently turned over and refreshed. Their waterings must be frequent in summer, but not in too great quantity. In the winter they must have it but seldom, a little once a week in open weather, and, in frost, once in a fortnight or three weeks, will be sufficient.

ANTHEMIS. Lin. Gen. Plant. 870. Chamomile.

The CHARACTERS are,

It is a plant with a compound flower, whose common empalement is hemispherical, composed of many scales which are equal. The border, or rays of the flower, is composed of many female florets, whose petals are stretched out like tongues on one side, and are indented in three parts at their extremity. The middle, or disk of the flower, is composed of many hermaphrodite florets, which are funnel-shaped, erect, and cut into five parts at the top. These have five short narrow stamina, which are crowned by cylindrical hollow summits. The germen is situated at the bottom, supporting a slender style, crowned by two reflexed stigma, which afterward becomes an oblong naked seed. The female florets have no stamina, but an oblong germen in the center, supporting two inflexed styles.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, entitled Syngenesia Polygamia superflua, the flowers of this section being composed of many florets, which are female and hermaphrodite, whose stamina are joined at the top.

The SPECIES are,

1. ANTHEMIS (*Nobilis*) foliis pinnato-compositis linearibus acutis subvillosis. Lin. Sp. Plant. 894. Chamomile with winged leaves, composed of many very narrow-pointed hoary segments. Chamæmelum nobile five Leucanthemum odoratum. C. B. P. 135. Common, or noble Chamomile.
2. ANTHEMIS (*Arvensis*) receptaculis conicis paleis setaceis feminibus coronato-marginatis. Flor. Suec. 704. Chamomile with a conical receptacle of bristly chaff, and bordered seeds. Chamæmelum inodorum. C. B. P. 136. May Weed.
3. ANTHEMIS (*Cotula*) receptaculis conicis paleis setaceis feminibus nudis. Lin. Sp. Plant. 894. Chamomile with a conicle receptacle, bristly chaff, and naked seeds. Chamæmelum foetidum. C. B. P. 135. May Weed.
4. ANTHEMIS (*Cota*) florum paleis rigidis pungentibus. Flor. Leyd. 172. Chamomile with stiff pungent chaff between the florets. Chamæmelum annuum ramosum cotulæ foetidæ floribus amplioribus capitulis spinosis. Mor. Hist. 3. p. 36.
5. ANTHEMIS (*Altissima*) erecta foliorum apicibus subspinosis. Lin. Sp. Plant. 893. Upright Chamomile with leaves ending with spines. Chamæmelum Leucanthemum Hispanicum magno flore. C. B. P. 135.
6. ANTHEMIS (*Maritima*) foliis pinnatis dentatis carnosius nudis punctatis caule prostrato, calycibus subtridentosis.

mentosis. Lin. Sp. Plant. 893. *Chamomile with fleshy pinnated leaves, and a branching trailing stalk.* Chamæmelum maritimum. C. B. P. 134.

7. ANTHEMIS (*Tomentosa*) foliis pinnatifidis obtusis planis, pedunculis hirsutis, foliosis calycibus tomentosis. Hort. Cliff. 415. *Chamomile with plain blunt leaves, winged at their extremity, hairy foot-stalks, and a leafy woolly empalement.* Chamæmelum maritimum incanum folio absinthii crasso. Boerh. Ind. 1. p. 110.

8. ANTHEMIS (*Mixta*) foliis simplicibus dentato-lacinatis. Lin. Sp. Plant. 894. *Chamomile with single, indented, cut leaves.* Chamæmelum Lusitanicum latifolium sive Coronopi folio. Breyn. Cent. 1. 49.

9. ANTHEMIS (*Pyrethrum*) caulibus unifloris decumbentibus foliis pinnato-multifidis. Lin. Hort. Cliff. 414. *Chamomile with single flowers on the stalks lying on the ground, and winged leaves.* Pyrethrum flore bellidis. C. B. P. 148. *Pellitory of Spain.*

10. ANTHEMIS (*Valentina*) caule ramoso foliis pubescentibus tripinnatis, calycibus villosis pedunculatis. Hort. Cliff. 414. *Chamomile with a branching stalk, multifid hairy leaves, and hairy foot-stalks.* Bupthalmum cotulae folio. C. B. P.

11. ANTHEMIS (*Tinctoria*) foliis bipinnatis serratis subtus tomentosis, caule corymbofo. Lin. Sp. 1263. *Chamomile with sawed winged leaves, woolly underneath, and flowers in a corymbus.* Bupthalmum Tanacetii minoris foliis. C. B. P. 134.

12. ANTHEMIS (*Arabica*) caule decomposito calycibus ramiferis. Hort. Cliff. 413. *Chamomile with a compound stalk, and a branching empalement.* Asteriscus annuus trianthophorus Crassas Arabicus dictus. Shaw. Afr. 58.

The first sort is the common Chamomile, which grows in plenty upon commons and other waste land. It is a trailing perennial plant, which puts out roots from the branches as they lie on the ground, whereby it spreads and multiplies greatly; so that whoever is willing to cultivate this plant, need only procure a few of the slips in the spring, and plant them a foot asunder, that they may have room to spread, and they will soon cover the ground. Formerly this plant was used for planting of walks, which, when mowed and rolled, looked well for some time, but as it was very subject to decay in large patches, the walks became unsightly, for which reason this was disused. The flowers of this sort are ordered for medicinal use, but the market people generally sell the double flowers, which are much larger, but not so strong as the single. The double sort is equally hardy, and may be propagated in the same manner.

The second sort is a common annual weed, which grows among corn; it flowers in May, so was called May Weed, though some have applied that title improperly to the *Cotula foetida*, which rarely flowers till late in June.

The fourth, fifth, and eighth sorts are annual plants, which grow naturally in Spain, Portugal, Italy, and the south of France, from whence their seeds have been brought to England, where the plants are preserved in botanic gardens for the sake of variety. They rise easily from seeds sown in the spring, and require no other culture but to thin the plants where they are too close, allowing them a foot and a half room each way, and clean them from the weeds. They flower in July, and their seeds ripen in September.

The sixth and seventh sorts are perennial plants, which grow naturally in Spain, Portugal, and Greece, from whence their seeds have been brought to England, and the plants are preserved in some curious gardens for the sake of variety. They are hardy and may be propagated by seeds, which should be sown in the spring upon poor land, where the plants will continue much longer than in good ground, and will require no other care but to keep them clean from weeds. These plants do not grow tall, but are bushy, so should be allowed room to grow. Their flowers are white, and continue from July to October, and the seeds ripen in autumn.

The ninth sort is the *Pellitory of Spain*, the roots of

which are used for the tooth-ach, being extremely warm; when they are applied to the part affected, they draw out the cold rheum, and are often serviceable in this particular. This is a perennial plant, with a long taper root like that of a Carrot, which grows naturally in Spain and Portugal, from whence the roots are brought to England. The branches of this trail upon the ground, and spread a foot or more each way; these are garnished with fine winged leaves, like those of the common Chamomile; at the extremity of each branch is produced one large single flower, like Chamomile, but much larger, the rays of which are of a pure white within, but purple on their outside. After the flowers are past, the receptacle swells to a large scaly cone; between these scales are lodged the seeds. It flowers in June and July, and the seeds are ripe in September; but unless the season is dry, the seeds do not ripen in England, for the wet falls between the scales, and rots the seeds in embryo.

The eleventh sort is a perennial plant, which is propagated by seeds; these may be sown on a bed of common earth in the spring, and when the plants are strong enough to remove, should be transplanted into large open borders, near shrubs, where they may have room to grow, for they spread very wide, therefore require three feet distance from other plants; in these large open spots they will make a pretty variety from June to November, during which time they continue in flower: some of these are white, others are of a sulphur, and some have yellow flowers, but these vary from seed; the eastern sorts grow taller, and the flowers are larger than the common, but in other particulars they are the same, though many have supposed them different species.

The seeds of the twelfth sort were brought from Africa by the late Dr. Shaw, which were distributed to many curious botanists in Italy, France, and England, where some of the plants were raised. This grows near two feet high, with an upright stem, having a single flower at the top, from whose empalement there are two or three foot-stalks put out horizontally, about two inches long, each having a single flower smaller than the first, like the *Childing Marigold*, or *Hen and Chicken Daisy*. The seeds of this should be sown in autumn, and treated in the same manner as is before directed for some other sorts, otherwise the seeds are seldom perfected in England.

ANTHERICUM. Lin. Gen. Plant. 380. Spiderwort.

The CHARACTERS are,

The flower hath no empalement, and is composed of six oblong blunt petals, which spread open. It hath six upright awl-shaped stamina, which are crowned by small summits, having four furrows. The germen which is situated in the center is three-cornered, supporting a single style which is as long as the stamina, crowned by a three-cornered blunt stigma. The germen afterward becomes an oval smooth capsule, having three furrows, opening in three cells, which are filled with angular seeds.

This genus of plants is ranged in the first section of Linnaeus's sixth class, entitled *Hexandria Monogynia*, from their flowers having six stamina and but one style.

The SPECIES are,

1. ANTHEMICUM (*Revolutum*) foliis planis scapo ramoso corollis revolutis. Lin. Sp. Plant. 310. *Anthericum with plain leaves, a branching stalk, whose petals turn backward.* Asphodelus foliis compressis asperis caule patulo. Tourn. Inst. R. H. 343.

2. ANTHEMICUM (*Ramosum*) foliis planis scapo ramoso corollis planis pistillo recto. Lin. Sp. Plant. 310. *Anthericum with plain leaves, a branching stalk, and plain reflexed petals.* Phalangium parvo flore ramosum. C. B. P. 29.

7. ANTHERICUM (*Annuum*) foliis carnosiss subulatis teretibus scapo subramoso. Hort. Upsal. 83. *Anthericum with awl-shaped, fleshy, taper leaves, and a branching stalk.* Asphodelus Africanus angustifolius luteus minor. Tourn. Inst. 343.
8. ANTHERICUM (*Altissimum*) acaule foliis carnosiss teretibus spicis florum longissimis laxis. Fig. Plant. pl. 39. *Tall African Spiderwort with taper fleshy leaves, and very long loose spikes of flowers.*
9. ANTHERICUM (*Offisfragum*) foliis ensiformibus filamentis lanatis. Flor. Suec. 268. *Anthericum with sword-shaped leaves, and downy stamina.* Asphodelus luteus palustris. Dod. Pempt. 208.
10. ANTHERICUM (*Catylactatum*) foliis ensiformibus perianthis trilobis filamentis glabris pistillis trigynis. Flor. Suec. 269. *Anthericum with sword-shaped leaves, an empalement with three lobes, smooth stamina, and three styles.* Phalangium alpinum palustre, Iridis folio. Segu.

The first sort grows naturally at the Cape of Good Hope; the roots of this are fleshy, and composed of tubers joined at the crown like those of the Asphodel; the stalk rises near two feet high, and branches out on each side, each branch being terminated by a loose spike of flowers, which are white, and the petals are turned backward to their foot-stalk. The leaves of this sort are flat, and the root is perennial, but the spikes decay in autumn.

The second sort hath a perennial root; the stalks of this rise about the same height as the former, sending out many lateral branches in like manner, which are terminated by loose spikes of flowers, which are white, but the petals are plain, and do not turn back as in the other sort.

The third sort hath plain leaves and an unbranching stalk, in which it chiefly differs from the former. The root of this is perennial.

The two next sorts grow naturally in Spain, Portugal, and other warm countries, and were more common some years ago in the English gardens than at present; for the severe winter in 1740, killed most of their roots. These flower in June and July, and their seeds are ripe in September. They are propagated by seeds, which should be sown in autumn; for those which are sown in the spring, never come up the same year, but remain in the ground till the following spring, or often miscarry. These should be sown in a bed of light sandy earth, in a warm situation, and when the plants come up, they must be kept clean from weeds during the summer; and in autumn, when their leaves decay, they should be carefully taken up, and transplanted into a bed of light earth, at a foot distance from each other. If the winter should prove severe, the bed should be covered with straw, Pease-haulm, or such light covering, to keep out the frost; or if some old tan from a hot-bed is spread over the ground, it will prevent the frost from penetrating the ground, and will preserve the roots. In this bed they may remain one year, by which time they will be strong enough to flower; therefore the following autumn they should be carefully taken up, so as not to break their roots, and planted in the borders of the flower-garden, where they will last several years, if they are not killed by frost; to prevent which, some rotten tan should be laid over the roots in winter, which will always secure them.

The fourth sort has been long preserved in many gar-

dens near London, and was formerly known among the gardeners by the title of Onion-leaved Aloe. This plant produces many ligneous branches from the root, each supporting a plant with long taper leaves, in shape of those of the Onion, which are full of a yellow pulp very juicy. These plants send out roots, which run down and fasten themselves into the earth, by which they multiply greatly. The flowers are produced on long loose spikes, are yellow, and appear at different times, so that the plants are not long destitute of flowers. These are succeeded by round smooth seed-vessels, which have three cells, filled with triangular seeds; but as the plant multiplies so fast by offsets, the seeds are little regarded. It grows naturally at the Cape of Good Hope, and requires a little shelter in winter; but in some mild seasons I have had plants live without any cover, which were planted close to a warm wall.

The fifth and sixth sorts grow close to the ground, never rising with any stalk. The fifth hath broad, flat, pulpy leaves, resembling those of some sorts of Aloe, so was formerly by gardeners called Aloe with flowers of Spiderwort. The leaves spread open; the flowers are produced on loose spikes, like the former, but are shorter: the flowers are yellow, and appear at different seasons. This is produced by offsets, which are put out in plenty, and must be planted in pots filled with light sandy earth, and in winter placed in the green-house, and treated as other hardy succulent plants, which come from the Cape of Good Hope, where this plant grows naturally. It must be kept pretty dry in winter, and if it is screened from frost, it will require no artificial warmth.

The sixth sort hath long, narrow, pulpy leaves, which are almost taper, but flattened on their upper side; this sends out many offsets, by which it may be increased plentifully. The flowers are yellow, and grow on long loose spikes, as the former; these appear at different seasons; those of the spring and summer are succeeded by seeds in great plenty, so may be easily propagated thereby, which ripen very well. It must be treated in the same manner as the former.

The seventh sort is annual: this is a low plant growing close to the ground, having pretty long succulent leaves which are taper, but flattened on their upper side; the flowers grow in loose spikes, which are shorter than either of the other sorts. They are yellow, and succeeded by round seed-vessels, like those of the former sorts; the plants perish soon after their seeds ripen. The seeds of this sort should be sown on a warm border of light earth in April, where they are to remain; and when the plants come up, they will require no other care but to keep them clean from weeds, and to thin them where they are too close. This sort flowers in July, and the seeds ripen in October.

The eighth sort never rises to a stalk, but the leaves come out close to the ground. These are long, taper, succulent, and of a sea-green colour, growing erect; the flower-stems rise between the leaves, and are near three feet long; the upper half being thinly garnished with yellow flowers, shaped like those of the other species. These appear at different seasons, so that the plants are seldom long destitute of flowers. This sort doth not send out offsets so freely as some of the others; but as it produces seeds annually, it may be had in plenty. It must be treated in the same manner as the fourth, fifth, and sixth sorts.

The ninth and tenth sorts grow naturally on bogs in most of the northern countries; the tenth is common in many parts of England, but particularly in Lancashire, from whence it had the title of Lancashire Asphodel; it also grows on a bog upon Putney-heath. The other grows naturally in Denmark, Sweden, and Lapland. These are both low plants, having narrow leaves, which grow close to the ground; the flower-stems rise about six inches high, being terminated by a loose spike of small yellow flowers. These differ from each other, the stamina of the tenth being woolly, whereas those of the other are smooth. These plants,

plants, growing naturally upon bogs, are with difficulty preserved in gardens.

ANTHERÆ [from ἄνθος flowery,] are the summits or little tops in the middle of a flower, supported by the stamina.

ANTHOLOGY [of ἄνθος, a flower, and λόγος, Gr. a word,] a discourse or treatise of flowers.

ANTHOLYZA. We have no English name for this plant.

The CHARACTERS are,

It hath an imbricated sheath growing alternate, which is permanent; the flower is of one leaf, tubulous, and opens above with compressed jaws. The upper lip is slender, long, erect, and waved; the two jaws are short, and joined at their base; the under lip is trifid, short, and the middle segment turns downward; it hath three long slender stamina, two of which are under the upper lip, and the other lies in the under lip; these are crowned by pointed summits. Under the flower is situated the germen, supporting a slender style the length of the stamina, which is crowned by a slender, trifid, reflexed stigma. The germen afterward becomes a roundish three-cornered vessel having three cells, in which are lodged many triangular seeds.

This genus of plants is ranged in the first section of Linnæus's third class, entitled Triandria Monogynia, the flowers having three stamina and one style.

The SPECIES are,

1. **ANTHOLYZA (Ringens)** corolla labiis divaricatis fauce compresso. Lin. Sp. Plant. 54. *Antholyza whose flower-lips spread asunder.* Gladiolus floribus rictum referens coccineus suprema lacinia erecta & fistulosa. Breyn. 21.

2. **ANTHOLYZA (Spicata)** foliis linearibus sulcatis floribus albis uno versu dispositis. Fig. Plant. pl. 40. *Antholyza with narrow furrowed leaves, and white flowers ranged on one side of the stalk.*

The first sort hath round, red, bulbous roots, from which arise several rough furrowed leaves, near a foot long, and half an inch broad; between these comes out the flower-stem immediately from the root, which rises two feet high, is hairy, and hath several flowers coming out on each side. These are of one leaf, cut into six unequal parts at the top: one of these segments is stretched out much beyond the other, standing erect; the margins are waved and closed together, wrapping up the three stamina. The flowers are red, and appear in June, and the seeds ripen in September.

The roots of the second sort are in shape and size like those of the Vernal Crocus, but the outer skin is thin and white; from this arises five or six long narrow leaves, which are deeply furrowed. Between these arise the flower-stem, which is a foot and a half high, bending on one side toward the top, where the flowers come out, ranged on one side, standing erect. These have each a spatha or sheath, of one leaf, divided into two, ending in points, which are permanent. The flower is of one leaf, having a long tube, but is divided into six unequal segments at the top, which spread open, their margins being waved and turned inward. The three stamina rise under the upper segment, which is larger than the others, and below is situated the trifid style, crowned with purple stigma. After the flower is past, the germen becomes a three-cornered seed-vessel, opening in three cells, which are filled with triangular seeds. The flowers of this sort are white, appear in May, and the seeds ripen in August.

These plants are natives of Africa, from whence their seeds have been obtained, and were first raised in the Dutch gardens, where one of the sorts has long been an ornament in the curious gardens of that country.

They are propagated by offsets, which the bulbous roots send forth in pretty great plenty; or by seeds, which are sometimes perfected in Europe. These seeds should be sown soon after they are ripe; for if they are kept out of the ground till the following spring, they often miscarry, or at least remain a year in the ground before they grow. If the seeds are sown in pots of light earth, and plunged into an old bed of

tan which has lost its heat, and shaded in the middle of the day in hot weather, the seeds will come up the following winter; therefore they must be kept covered with glasses to screen them from cold, otherwise the young plants will be destroyed. These may remain in the pots two years, if the plants are not too close, by which time they will have strength enough to be planted each into a separate small pot filled with light earth. The time for transplanting of these roots is in July or August, when their leaves are decayed. In summer the pots may be placed in the open air, but in winter they must be removed, and placed under a hot-bed frame, for they are not very tender; but where any damp arises, it is very apt to occasion a mouldiness upon their leaves. The roots shoot up in autumn, and the flowers begin to appear in May; the seeds ripen in August, and soon after their leaves and stalks decay; when the roots may be taken up, and kept six weeks or two months out of the ground, so may be easily transported from one country to another at that time. These flowers are ornamental when they appear, and they are plants which require but little culture, so deserve a place in every good garden.

ANTHOSPERMUM, Amber-tree, vulgò.

The CHARACTERS are,

It is male and female in different plants; the male flowers have no petals, but a coloured empalement of one leaf, which is cut into four parts almost to the bottom. Out of the bottom arises four slender stamina, crowned with oblong square summits, having a deep furrow through their middle. The female flowers have the same structure as the male, but have no stamina; instead of which, there is an oval germen, situated in the bottom, supporting two recurved styles crowned with a slender stigma. The germen afterward becomes a roundish capsule having four cells, which contain several angular seeds.

Dr. Linnæus has ranged this genus in his twentieth class of plants, but it properly belongs to his twenty-second, because the plants are male and female in different plants; whereas those of his twenty-third, have male, female, and hermaphrodite flowers on the same plant.

ANTHOSPERMUM (Æthiopicum) foliis lævibus. Hort. Cliff. 455. *Amber-tree with smooth leaves.*

This plant has been long known in the curious gardens, under the title of Frutex Africanus, ambram spirans, or *Amber-tree*.

It is preserved in most curious gardens which have collections of tender plants, and is easily propagated by planting cuttings during any of the summer months, in a border of light earth; which will take root in six weeks time, provided they are watered and shaded as the season may require: or if these cuttings are planted in pots, and plunged into a very moderate hot-bed, they will take root sooner, and there will be a greater certainty of their growing. Afterward they should be taken up, with a ball of earth to their roots, and planted into pots filled with light sandy earth, and may be exposed to the open air until October; at which time they should be removed into the conservatory, where they should be placed as free as possible from being over-hung with other plants; and, during the winter season, they must be refreshed with water, but should not have too much given them each time; and should have as much air admitted to them as the weather will permit, for if they are kept too close, they will be subject to grow mouldy, and generally decay soon after; so that if the green-house is damp, it will be difficult to preserve these plants through the winter.

The beauty of this shrub is in its small ever-green leaves, which grow as close as heath; which being bruised between the fingers, emit a very fragrant odour. These plants must be frequently renewed by cuttings, for the old plants are very subject to decay, seldom continuing above three or four years.

It is but of late years there have been any of the female plants in the gardens, for all those which were formerly in the gardens, were the male, which being

propagated by cuttings had been continued, so that no seeds were ever produced in England till within a few years past, when I received some seeds from the Cape of Good Hope, from which I raised many plants of both sexes, and a few among them with hermaphrodite flowers, which have produced seeds, from which many plants have been raised.

ANTHYLLIS. Lin. Gen. Plant. 773. Vulneraria. Tourn. Barba Jovis. Tourn. Ladies Finger, or Kidney Vetch.

The CHARACTERS are,

It hath a swelling, hairy, permanent empalement of one leaf, which is divided at the top into five equal parts. The flower is of the butterfly kind, having a long standard reflexed on both sides beyond the empalement; the two wings are short; the keel is of the same length, and compressed. There are ten stamina, which rise together, and are crowned by single summits. In the center is situated an oblong germen, supporting a single style, crowned by a blunt stigma: the germen afterward becomes a small roundish pod inclosed by the empalement; having one or two seeds.

This genus is ranged in Linnæus's seventeenth class of plants, entitled Diadelphia Decandria, the flowers having ten stamina joined in two bodies.

The SPECIES are,

1. ANTHYLLIS (*Tetraphylla*) herbacea foliis quaternopinnatis floribus lateralibus. Hort. Upsal. 221. *Herbaceous Kidney Vetch with winged leaves, having four lobes, and flowers growing from the side of the stalks.* Vulneraria pentaphyllos. Tourn. Init.
2. ANTHYLLIS (*Vulneraria*) herbacea foliis pinnatis inæqualibus capitulo duplicato. Lin. Sp. Plant. 719. *Kidney Vetch with unequal winged leaves and double heads.* Vulneraria supina flore coccineo. Raii Syn. Ed. 3. p. 325.
3. ANTHYLLIS (*Rustica*) herbacea foliis pinnatis inæqualibus foliolis caulinis linear lanceolatis floribus capitatis simplicibus. *Herbaceous Kidney Vetch with unequal winged leaves, whose lobes are narrow, spear-shaped, and single heads of flowers, called Ladies Fingers.* Vulneraria rustica. J. B. 11. p. 362.
4. ANTHYLLIS (*Montana*) herbacea foliis pinnatis æqualibus capitulo terminali secundo, floribus obliquatis. Lin. Sp. Plant. 719. *Herbaceous Woundwort with equal winged leaves, terminated by the head of flowers, which are oblique.* Astragalus purpureus. Dalechampii 1347. *Purple Milk Vetch.*
5. ANTHYLLIS (*Cornicina*) herbacea foliis pinnatis inæqualibus capitulis solitariis. Lin. Sp. Plant. 719. *Herbaceous Woundwort, with unequal winged leaves, and a single head of flowers.*
6. ANTHYLLIS (*Barba Jovis*) fruticosa foliis pinnatis æqualibus floribus capitatis. Hort. Cliff. 371. *Shrubby Woundwort, with leaves equally winged, and flowers collected in a head.* Barba Jovis pulchrè lucens. J. B. 1. p. 385. *Jupiter's Beard, or Silver Bush.*
7. ANTHYLLIS (*Cytisoides*) fruticosa foliis ternatis inæqualibus calycibus lanatis lateralibus. Lin. Sp. Plant. 720. *Shrubby Woundwort, with three unequal leaves, and a downy flower-cup growing from the sides.* Cytisus incanus folio medio longiore. C. B. P. 390.
8. ANTHYLLIS (*Erinacea*) fruticosa spinosa foliis simplicibus. Lin. Sp. Plant. 720. *Shrubby prickly Woundwort, with single leaves.* Genista Spartium spinosum foliis lenticulæ floribus ex cæruleo purpurascens. C. B. P. 394.
9. ANTHYLLIS (*Hermannia*) fruticosa, foliis ternatis subpedunculatis, calycibus nudis. Lin. Sp. Plant. 1014. *Shrubby Woundwort of Crete, with ternate leaves, and naked flower-cups.* Barba Jovis Cretica, linariæ folio, flore luteo parvo. Tourn. Cor. 44.
10. ANTHYLLIS (*Heterophylla*) fruticosa, foliis pinnatis, floralibus ternatis. Lin. Sp. Plant. 1013. *Shrubby Woundwort of Portugal, with winged leaves, but those near the flowers ternate.* Barba Jovis minor Lusitanica, flore minimo variegato. Tourn. Inf. 651.

The first sort grows naturally in Spain, Italy, and Sicily. This is an annual plant, with trailing branches, which spread flat on the ground; the leaves grow by fours at each joint, and the flowers come out in clus-

ters on the sides of the stalks, having large swelling empalements, out of which the extreme parts of the petals do but just appear; these are of a yellow colour, and are succeeded by short pods inclosed in the empalement. It flowers in June and July, and the seeds ripen in September. The seeds of this sort should be sown on a bed of light earth in April, where the plants are to remain, and will require no other care, but to thin them to the distance of two feet, and keep them clean from weeds.

The second sort grows naturally in Spain and Portugal, from both which countries I have received the seeds; it also grows wild in Wales, and the isle of Man. This is a biennial plant, having single leaves at bottom, which are oval and hairy; but those which grow out of the stalks are winged, each being composed of two or three pair of lobes terminated by an odd one: the flowers grow collected into heads at the top of the stalks, these are of a bright scarlet colour, so make a pretty appearance: it flowers in June and July, and the seeds ripen in October. When the plants of this sort grow on poor land, they will sometimes continue three years, but in gardens they seldom last longer than two.

The third sort grows naturally upon chalky grounds in many parts of England, so is rarely admitted into gardens. Dr. Linnaeus supposes this and the former sort to be the same, but from having cultivated these for many years, I can affirm they are different species, never altering from seed. The leaves of this sort are much narrower than those of the former, and have generally one or two pair of lobes more in each. The heads of flowers in this species are single, whereas the other has generally double heads; add to these, the root being perennial, which makes an essential difference between them.

The fourth sort is a perennial plant with trailing branches, garnished with winged leaves, which have an equal number of hairy lobes at the extremity of the branches; the flowers are produced in heads, these are of a purple colour, and globular form. This sort grows naturally on mountains in the south of France and Italy, from whence I have received the seeds. It is propagated by seeds, which may be sown either in the autumn or spring: those which are sown in the autumn, will rise the following spring, and more certainly grow, than those which are sown in the spring, which seldom grow the same year. When the plants come up, they must be kept clean from weeds; and where they are too close together, they must be thinned. The following autumn, they should be transplanted to the places where they are to remain, and will require no particular management afterward. This sort flowers in June and July, and the seeds ripen in October.

The fifth sort approaches near to the third, but the leaves are hoary, and the flowers are produced on the side of the branches; these are yellow, and collected into small heads. It is an annual, or at most a biennial plant; for when it flowers early in the summer, it commonly decays soon after the seeds are ripe; whereas those plants which flower later in the season, and do not perfect seeds, will abide another year. This may be propagated by seeds, in the same manner as the former.

The sixth sort is the Barba Jovis, or Jupiter's Beard, by many called Silver Bush, from the whiteness of its leaves. This is a shrub which often grows ten or twelve feet high, and divides into many lateral branches, garnished with winged leaves, composed of an equal number of narrow lobes, which are very white and hairy; the flowers are produced at the extremity of the branches, collected into small heads; these are of a bright yellow colour, and appear in June; sometimes they are succeeded by short woolly pods, containing two or three kidney-shaped seeds; but unless the season proves warm, they do not ripen in this country. It is propagated either by seeds or cuttings; if by seeds, they should be sown in the autumn, in pots filled with light earth, and placed under a frame

a frame in winter to protect them from frost. The following spring the plants will rise, and when they are strong enough to remove, they should be each planted in a small pot filled with light earth, and placed in the shade till they have taken new root; after which, they may be placed with other hardy exotic plants, in a sheltered situation, where they may remain till October, when they must be removed into shelter. These plants are always housed in winter, yet I have had some of them live abroad three or four years, which were planted against a south-west aspect wall. It may also be propagated by cuttings, which may be planted during any of the summer months, observing to water and shade them until they have taken root. When the cuttings have taken good root, they should be planted in pots, and treated in the same manner as the former.

The seventh sort is a low shrub, seldom rising above two feet high, but sends out many slender branches, garnished with hoary leaves, which are sometimes single, but generally have three oval lobes, the middle being longer than the other two; the flowers are yellow, and come out from the side of the branches, three or four joined together, having woolly empalements, but these are rarely succeeded by seeds in England. It may be propagated by cuttings or seeds, in the same manner as the former sort, and treated as hath been directed for that. This has been an old inhabitant in the English gardens.

The eighth sort grows naturally in Spain and Portugal, from whence I have received the seeds. This is a shrub which grows nine or ten feet high, having the appearance of one sort of Gorse or Whin, but it hath round leaves growing single. It will live in the open air in mild winters, but hard frost will destroy it. It is propagated by seeds only.

The ninth sort grows naturally in Crete, and also in Palestine; this was formerly in some of the English gardens, but the severe winter of 17 $\frac{1}{2}$, destroyed most (if not all the plants) in this country, since which time I have not seen it. This shrub grows five or six feet high, the branches are garnished with oblong ternate leaves; the flowers, which are yellow, are produced in small clusters on the side of the branches; these appear in July and August, but are not succeeded by seeds in this country.

This is propagated by cuttings, which should be planted the beginning of June, and if they are closely covered with a bell-glass, and properly shaded, they will put out roots by the end of August, when they should be carefully taken up, and each planted in a small pot, filled with light earth, and placed in the shade until they have taken new root; when they may be placed in the open air till October, and then should be removed into shelter, and treated in the same way as other hardy green-house plants.

The tenth sort grows naturally in Portugal and Spain: this is a very low shrubby plant, whose branches spread near the ground, garnished with silvery winged leaves, which are acute-pointed; the flowers are produced toward the extremity of the branches; these are not succeeded by seeds in England, but the plant is propagated by cuttings in the same manner as the former, and the plants require the same treatment.

ANTIRRHINUM [which in composition sometimes indicates a likeness, *Ἀντίρρινον*, of *ἄντι* and *ῥιν*, the nostrils, because it represents a nose:] Snap-dragon, or Calves-snout.

The CHARACTERS are,

The empalement is of one leaf, cut into five parts, the two upper segments being longer than the lower. The flower is ringent, having an oblong tube, divided at the top into two lips, which are closed at the jaw. The upper lip is cut into two, and reflexed on each side; the under lip is divided into three obtuse parts: in the bottom is situated an obtuse nectarium, which is not prominent. There are four stamina which are included in the upper lip, two being longer, and two shorter, crowned by short summits. In the center is placed a roundish germen, supporting a single style, crowned with an obtuse stigma. The germen after-

ward becomes a round obtuse capsule, having two cells, which are full of small angular seeds.

This genus is ranged in Linnæus's fourteenth class of plants, entitled *Didynamia Angiosperma*, the flower having two long and two short stamina, and many seeds included in a capsule. To this genus Linnæus has joined the *Linaria* and *Asarina*; but as the flowers of the *Linaria* have spurs to their petals, and the nectarium being very prominent, which are not so in this genus, so it should be separated from it.

The SPECIES are,

1. **ANTIRRHINUM** (*Minus*) foliis lanceolatis obtusis alternis caule ramosissimo diffuso. Hort. Cliff. 324. Snap-dragon with obtuse spear-shaped leaves growing alternate, and a diffused branching stalk. *Antirrhinum arvense minus*. C. B. P. 212.
2. **ANTIRRHINUM** (*Orontium*) floribus subspicatis, calycibus digitatis corolla longioribus. Hort. Upsal. 176. Snap-dragon with spiked flowers, and fingered empalement longer than the flower. *Antirrhinum arvense majus*. C. B. P. 212.
3. **ANTIRRHINUM** (*Majus*) foliis lanceolatis petiolatis calycibus brevissimis racemo terminali. Vir. Cliff. 61. Snap-dragon with spear shaped leaves having foot-stalks, and very short flower-cups, terminated by a spike of flowers. *Antirrhinum majus alterum folio longiore*. C. B. P. 211.
4. **ANTIRRHINUM** (*Latifolium*) foliis lanceolatis glabris, calycibus hirsutis racemo longissimo. Snap-dragon with smooth spear-shaped leaves, hairy flower-cups, and a very long spike of flowers. *Antirrhinum latifolium amplexo pallido flore*. Bocc. Mus. 2. 49.
5. **ANTIRRHINUM** (*Italicum*) foliis linearilanceolatis hirsutis racemo brevioris. Snap-dragon with narrow, hairy, spear-shaped leaves, and a shorter spike of flowers. *Antirrhinum longifolium majus Italicum flore amplexo niveo lactescente*. H. R. Par.
6. **ANTIRRHINUM** (*Siculum*) foliis linearibus floribus petiolatis axillaribus. Snap-dragon with narrow leaves and flowers, with foot-stalks proceeding from the wings of the leaves. *Antirrhinum siculum linariæ folio niveo flore*. Bocc. Mus.

The two first sorts grow naturally on arable land in many parts of England, so are seldom admitted into gardens; these are both annual plants, which come up from scattered seeds. They flower in June and July, and their seeds are ripe in September.

The third sort is not a native of England, but having been first brought into gardens, the seeds have scattered about in so great plenty, that it is become very common upon walls and old buildings in many parts of England. Of this sort there are several varieties, which differ in the colour of their flowers, some having red flowers with white mouths, some with yellow mouths, others have white flowers, with yellow and white mouths. There is also one with striped leaves. The last is propagated by slips and cuttings, which readily take root any time in the spring or summer. The different colours of the flowers are variable from seeds.

The fourth sort grows naturally in the islands of the Archipelago, from whence I received the seeds. The leaves of this are much broader, the flowers greatly larger, and the spikes longer, than in any of the other sorts. The colours of the flowers are as changeable in this sort as the former, when raised from seeds; but as this is the most specious kind, so it better deserves propagating than the common, especially as it is equally hardy.

The fifth sort has long narrow leaves, which are hairy; the flowers are large, and the spike is shorter than the former; there are some varieties in the colour of the flowers of this sort, but it is equally hardy with the common sort.

The sixth sort is an annual plant, which seldom grows more than a foot high; the leaves of this are very narrow and smooth; the flowers come out from the wings of the leaves single, standing on long foot-stalks; these are very white, with a dark bottom. If the seeds of this sort are permitted to scatter, the plants

plants will come up, and require no other care but to thin them and keep them clean from weeds.

The third, fourth, and fifth sorts are raised from seeds, which should be sown in a dry soil, which is not too rich, either in April or May; and in July the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, for flowering the same autumn, but then they are not so likely to endure the winter; and if the autumn prove bad, they will not perfect their seeds.

These plants grow extremely well upon old walls or buildings, in which places they will endure for several years; whereas those planted in gardens seldom last longer than two years, unless they are planted in a very poor soil, and the flowers often cropped, and not suffered to seed; but any of these sorts may be continued, by planting cuttings in any of the summer months, which will easily take root.

All the sorts of Snap-dragons are pretty ornaments in a garden, and requiring very little culture, are rendered more acceptable. They are all hardy plants, and will resist the cold of our winters extremely well, especially if they are planted on a dry, gravelly, or sandy soil; for when they are planted in a rich moist soil, they will grow very luxuriant for a time, but are very subject to rot in autumn or winter; and are much more susceptible of cold, than when they are in a dry, hungry, rocky soil; so that these plants may be placed amongst stones, or they will grow in the joints of old walls, where they may be placed so as to render some abject part of a garden very agreeable, for they will continue in flower several months; and if the seeds are permitted to shed, there will be a continual supply of young plants, without any trouble.

Wherever these plants are designed to grow on walls, or on a rocky barren soil, the seeds should be sown the beginning of March, where they are designed to remain; (for if the plants are first raised in a better soil, and afterward transplanted into those places, they seldom succeed well.) When the plants are come up, they will require no other culture but to keep them clear from weeds; and where they come up too thick, to pull some of them out, so as to give them room to grow. In July these sorts will begin to flower, and will continue flowering till the frost prevents them. Those plants which grow on walls, will have strong woody stems, which will continue two or three years or more, and are rarely hurt by frost.

A P A R I N E [this plant is so called, because it is very rough; it is called Philanthron, of φιλέω, to love, and ἄνθρωπος, man; because if a person walks in uncultivated places, the plant not only applies itself to his garments, but it holds them, as if it had a mind to bind man with an amicable band:] Goose-grass or Clivers.

The common sort grows wild almost every where, the seeds sticking to the cloaths of people that pass by where they grow: it is sometimes used in medicine, but it is too common a weed to be admitted into a garden.

There are some other sorts of this plant which are kept in botanic gardens for the sake of variety, which I shall beg leave to enumerate here.

1. **A P A R I N E** *femine lævi*. Tourn. *Goose-grass with a smooth seed*. This is under *Gallium* in Linnaeus.
2. **A P A R I N E** *femine coriandri saccharati*. Park. *Theat. Goose-grass with sweet seeds like Coriander*.
3. **A P A R I N E** *pumila supina, flore cæruleo*. Tourn. *Low trailing Goose-grass, with a blue flower*. The two last are included in Linnaeus's genus of *Vailantia*.

All these plants, if they are permitted to scatter their seeds, will maintain themselves in a garden without any other culture, than that of preventing other weeds from over-growing them, these being all very low plants.

The first sort grows wild in Cambridgeshire; as doth the third about Liphoeck in Hampshire, where I have gathered it.

A P E T A L O U S plants, [of ἀ privative, and πῆλον, a flower-leaf, Gr.] are such as have no petals or flower-leaves.

A P H A C A. See **LATHYRUS**.

A P I C E S [of Apex, Lat. a top or point] these are called summits by Vaillant, and are those little knobs that grow on the top of the stamina in the middle of the flower: which are generally supposed to be a kind of male sperm; which when ripe, diffuses itself to every part of the flower, and fecundates the ovarium and renders it fruitful.

A P I O S. See **GLYCINE**.

A P I U M [Apium is so called, as some say, of Apes, bees, because bees are said to be delighted very much with it,] Parsley.

The **CHARACTERS** are,

It is a plant with an umbelliferous flower; the rays of the great umbel are few, but those of the smaller are many; the involucre is in some species of one leaf, and in others of many; the petals of the greater umbel are uniform; these are round, equal, and turn inward. Each flower has five stamina, crowned by roundish summits. Under the flower is situated the germen, supporting two reflexed styles, crowned by blunt stigma; the germen afterward becomes an oval channelled fruit, dividing into two parts, having two oval seeds channelled on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnaeus's fifth class, entitled Pentandria Digynia, the flowers having five stamina and two styles.

The **SPECIES** are,

1. **A P I U M** (*Petroselinum*) foliolis caulinis linearibus involucrellis minutis. Hort. Cliff. 108. *Parsley with very narrow leaves on the flower-stalks. Apium hortense vel petroselinum vulgò. C. B. P. Common Parsley.*
2. **A P I U M** (*Crispum*) foliis radicalibus amplioribus crispis caulinis ovato-multifidis. *Parsley with the lower leaves very broad and curled, the upper oval, and cut into many segments. Apium vel petroselinum crispum. C. B. P. 153. Curled Parsley.*
3. **A P I U M** (*Latifolium*) foliis radicalibus trifidis, serratis, petiolis longissimis. *Parsley with under leaves divided into three parts, which are sawed, and have very long foot-stalks. Apium hortense latifolium maxima crassissima suavi & eduli radice. Boerh. Ind. alt. The large rooted Parsley.*
4. **A P I U M** (*Graveolens*) foliolis caulinis cuneiformibus. Hort. Cliff. 107. *Parsley with the lower leaves fashioned like a wedge. Apium palustre five apium officinarum. C. B. P. 154. Smallage.*
5. **A P I U M** (*Dulce*) foliis erectis, petiolis longissimis foliolis quinque lobatis serratis. *Parsley with upright leaves, having very long foot-stalks, and the smaller leaves composed of five sawed lobes. Apium dulce ceteri Italorum. Inst. R. H. 305. Upright Celery.*
6. **A P I U M** (*Rapaceum*) foliis patulis, petiolis brevibus, foliolis quinque serratis, radice rotundo. *Parsley with spreading leaves, having short foot-stalks, the smaller leaves having five lobes, and a round root. Apium dulce degener, radice rapacea. Just. Celeriack, or Turnep-rooted Celery.*
7. **A P I U M** (*Lusitanicum*) foliis radicalibus tribolatis, caulinis quinque-lobatis crenatis. *Parsley with under leaves having three lobes, and those on the stalks five, which are indented. Apium Lusitanicum maximum, folio trilobato flore luteolo. Boerh. Ind. alt.*

The first sort is the common Parsley, which is generally cultivated for culinary use; and is what the College of Physicians have directed to be used in medicine, under the title of *Petroselinum*; for when Apium is prescribed, the Smallage is always intended.

The second sort has generally been supposed to be only a variety of the first, but from many years trial I have always found, that if the seeds are carefully saved from plants of the curled-leaved Parsley, it will constantly produce the same; but there are few persons who will be at the trouble to save the seeds so carefully, as not to have some of the common sort mixed with it; for when seeds are bought at the shops,

shops, there is generally a mixture of both: therefore the only method to have it good, is to separate all those plants which have plain leaves from the curled, as soon as they are distinguishable, leaving only such as are of the right kind; if this is duly observed, the seeds will constantly produce the same.

The third sort is chiefly cultivated for their roots, which are now pretty commonly sold in the London markets; the leaves of this sort have much longer foot-stalks, and their subdivisions are not so numerous as in the common Parsley; the lobes of the leaves are much larger, and of a darker green, so that it is easily distinguished from the common sort by its leaves, but the roots are six times as large as the common Parsley can be brought to with the utmost culture. I have sown the seeds of both sorts for several years on the same spot of ground, and have thinned the plants when young, to an equal distance, and given the same culture to both; but when their roots were taken up, those of the common sort were not larger than a man's little finger, but the other were as large as full grown Carrots, which were very tender and sweet, whereas the other were stringy and strong; and this difference constantly holds, so it may be allowed to be specifically different. This sort was many years cultivated in Holland, before the English gardeners could be prevailed on to sow it. I brought the seeds of it from thence in 1727, and would then have persuaded some of the kitchen-gardeners to make trial of it, but they refused to accept of it, so that I cultivated it several years before it was known in the markets.

The fourth sort is commonly known by the title of Smallage. This is what the physicians intend when they prescribe Apium. Dr. Linnæus has joined to this the Celery, supposing them to be the same, and the only difference to arise from culture, but herein he is greatly mistaken; for I have cultivated the Smallage in gardens forty years, to try if by art it could possibly be brought to the same goodness as Celery, but have not been able to alter it from its original; all that can be done by culture, is to bring it to a larger size than it naturally grows wild, and by earthing it, to give it a whiteness; but it will not grow tall as Celery, nor will it rise with a strait stem, but sends out many suckers near the root, and when it is blanched, retains its strong rank taste, which no culture can alter, therefore I make no doubt of its being a distinct species.

The fifth sort is the Celery before-mentioned, and the sixth sort was supposed to be a degenerate species from it, but I cannot agree to this opinion; for from many years trial I have never found it vary. The leaves of this sort are short, when compared with those of the other, and spread open horizontally; the roots grow as large as the common Turneps. The difference which I have observed to arise from the culture, has been only in the size of the roots; those on rich ground, which were properly cultivated were much larger than those on poorer land, but the leaves and outward appearance of the plants were never altered, so that I make no doubt of its being a different species.

The seeds of the seventh sort I received from the royal garden at Paris, many years since, where it had been long preserved, and maintained its difference; and from more than twenty years cultivating it in the garden at Chelsea, I have found the same, so that I cannot doubt of its being different from all the other species.

The broad-leaved Garden Parsley, mentioned by Casper Bauhin, and the round-leaved Portugal Parsley, mentioned by Tournefort, I believe are only varieties of the common Parsley; for if they are distinct species, all the seeds which I have received from different parts of Europe, under those titles, have been wrong; for the plants which have risen from those seeds, have always proved to be the common sort.

As Tournefort, and many other botanists, have enumerated all the varieties of plants which were found

in the gardens, and did not distinguish which of them were specifically different; so Dr. Linnæus has gone into the other extreme, and supposed many plants, which are permanently different, to be only accidental varieties, arising from culture. But as he is now cultivating as many plants as the inclemency of the climate where he is situated, will permit, there is no doubt of his reforming his error, in this particular, when he finds what plants retain their specific difference.

The common Parsley must be sown early in the spring, for the seeds remain a long time in the earth, the plants seldom appearing in less than six weeks after the seeds are sown. This sort is generally sown in drills by the edges of borders in the kitchen-gardens near London, because it is much easier to keep it clear from weeds, than if the seeds are sown promiscuously on a border, and the Parsley is much sooner cut for use: but when the roots are desired for medicinal use, then the seeds must be sown thin; and when the plants are come up, they should be hoed out single, as is practised for Carrots, Onions, &c. observing also to cut up the weeds: if this be observed, the roots will become fit for use by July or August, and continue so till spring.

There are some persons who are afraid to use Parsley in their kitchens, lest they should suffer by having the lesser Hemlock mixed with it, whose leaves are so like Parsley, that persons who are not skilled in botany, may be easily deceived; which being a noxious plant, several persons have been injured by eating it: but to prevent this, I have for many years cultivated the sort with curled leaves, which is so unlike the Hemlock, that no person, however ignorant, can mistake one for the other, and have constantly advised those of my acquaintance to do the same; for the curled sort is equally good as the common Parsley, and I have constantly found the seeds, saved from the curled sort, to produce the same.

The common Parsley is, by some skilful persons, cultivated in fields for the use of sheep, it being a sovereign remedy to preserve them from the rot, provided they are fed twice a week for two or three hours each time with this herb; but hares and rabbits are so fond of it, that they will come from a great distance to feed upon it; and in countries where these animals abound, they will destroy it, if it is not very securely fenced against them; so that whoever has a mind to have plenty of hares in their fields, by cultivating Parsley, will draw all the hares of the country to them, and this will preserve them sound.

The best time for sowing it in the fields is about the middle or latter end of February; the ground should be made fine, and the seeds sown pretty thick, in drills drawn at about a foot asunder, that the ground may be kept hoed between the drills, to destroy the weeds, which, if permitted to grow, will soon overrun the Parsley. One bushel of seed will sow an acre of land.

The great Garden Parsley is now more known to us in England than it was some years past. In Holland it has been long common in all their markets: they bring these roots in bunches, as we do young Carrots to market in summer; and the roots are much of the same size: it is called Petroseline Wortle by the Dutch, who are very fond of it for water souche.

It may be cultivated by sowing the seeds in good ground early in the spring; and in April, when the plants are up, cut them out with a hoe (as is practised for young Carrots) to about five or six inches square, and keep them constantly clean from weeds; and in July the roots will be fit to draw for use, and may be boiled and eaten as young Carrots; and are very palatable and wholesome, especially for those who are troubled with the gravel.

But if these plants are cut out, to allow them more room, if the soil is good, the roots will grow to the size of a middling Parsnep, by September.

Smallage is a common weed by the side of ditches and brooks of water, in many parts of England, so

A P I

to that it is seldom cultivated in gardens; but if any person is willing to propagate it, the seeds should be sown soon after they are ripe, on a moist spot of ground; and when the plants come up, they may be either transplanted in a moist soil, or hoed out, and left six or eight inches asunder, where they may remain for good. The seed of this plant is one of the lesser warm seeds; both the herb and seeds are used in medicine.

The seeds of the two sorts of Celery should be sown at two or three different times, the better to continue it for use through the whole season, without running up to seed. The first sowing should be in the beginning of March, upon a gentle hot-bed; the second may be a fortnight or three weeks after, which ought to be in an open spot of light earth, where it may enjoy the benefit of the sun; the third time of sowing should be the end of April, or beginning of May, which ought to be in a moist soil; and if exposed to the morning sun only, it will be so much the better, but it should not be under the drip of trees.

The seeds which are sown in the hot-bed will come up in about three weeks or a month after sowing, when the plants should be carefully cleared from weeds; and if the season prove dry, they must be frequently watered; and in about a month or five weeks after it is up, the plants will be fit to transplant: you must therefore prepare some beds of moist rich earth, in a warm situation, in which you should prick these young plants, at about three inches square, that they may grow strong; and if the season should prove cold, the beds must be covered with mats, to screen the plants from morning frosts, which would retard their growth: you must also observe, in drawing these plants out of the seed-beds, to thin them where they grow too thick, leaving the small plants to get more strength before they are transplanted; by which means one and the same seed-bed will afford three different plantings, which will accordingly succeed each other for use.

You must observe, if the season proves dry, to keep it diligently watered after it is transplanted, as also to clear the seed-beds from weeds; and after every drawing, keep them duly watered, to encourage the small plants left therein.

The middle of May some of the plants of the first sowing will be fit to transplant for blanching, which should be planted in a moist, rich, light soil, upon which the first planted Celery will often grow to be twenty inches long in the clean blanched parts, which upon a poor or dry soil seldom rises to be ten inches.

The manner of transplanting it is as follows: after having cleared the ground of weeds, you must dig a trench by a line about ten inches wide, and six or seven inches deep, loosening the earth in the bottom, and laying it level; the earth that comes out of the trench should be equally laid on each side the trench, to be ready to draw in again to earth the Celery as it advances in height. These trenches should be made at three feet distance from each other; then plant the plants in the middle of the trench, at about four or five inches distance, in one strait row, having before trimmed the plants, and cut off the tops of the long leaves; when they are planted you must observe to close the earth well to their roots, and to water them plentifully until they have taken fresh root; after which time it will be needless, except in dry soils, or very dry seasons: as these plants advance in height, you must observe to draw the earth on each side close to them, being careful not to bury their hearts, nor ever to do it but in dry weather, otherwise the plants will rot.

When the plants have advanced a considerable height above the trenches, and all the earth, which was laid on the sides thereof, hath been employed in earthing them up; you must then make use of a spade to dig up the earth between the trenches, which must also be made use of for the same purpose, continuing from time to time to earth it up, until it is fit for use.

The first of your planting out will, perhaps, be fit for use by the beginning of July, and will be succeeded by the after plantations; and if the latter sowings

A P O

are rightly managed, there will be a succession of Celery for use till April; but you should observe to plant the last crop in a drier soil, to prevent its being rotted with too much wet in winter; and also if the weather should prove extreme sharp, you will do well to cover your ridges of Celery with some Pease-haulm, or some such light covering, which will admit the air to the plants; for if they are covered too close, they will be very subject to rot; by this means you may preserve your Celery in season a long time, but you must remember to take off the covering whenever the weather will permit, otherwise it will be apt to cause the Celery to rot. By this method of covering the Celery, the frost will be kept out of the ground; so it may be always taken up for use when it is wanted, which, if neglected, it cannot be taken up in hard frost. The Celery, when fully blanched, will not continue good above three weeks or a month before it will rot or pipe: therefore, in order to continue it good, you should have at least six or seven different seasons of planting; so that if it be only intended to supply a family, there need not be much planted at each time, but this must be proportioned according to the quantity required.

The other sort of Celery, which is commonly called Celeriac, is to be managed in the same manner as is directed for the Italian Celery, excepting that this should be planted upon the level ground, or in very shallow drills, for this plant seldom grows above eight or ten inches high, so requires but little earthing up; the great excellency of this being in the size of the root, which is often as large as ordinary Turneps. It should be sown about the middle of March, upon a rich border of earth, and, in dry weather, constantly watered, otherwise the seeds will not grow: when the plants are large enough to transplant out, they should be placed eighteen inches asunder, row from row, and the plants six or eight inches distant in the rows; the ground must be carefully kept clean from weeds, but this sort will require but one earthing up, which should not be performed until the roots are nearly grown: both these sorts of Celery delight in a rich, light, moist soil, where they will grow to a much larger size, and will be sweeter and tenderer than on a poor or dry ground.

The best method to save this seed, is to make choice of some long good roots of the upright Celery, which have not been too much blanched, and plant them out at about a foot asunder in a moist soil, early in the spring; and when they run up to seed, keep them supported with stakes, to prevent their being broken down by the winds: and in July, when the seed begins to be formed, if the season should prove very dry, it will be proper to give some water to the plants, which will greatly help their producing good seeds. In August these seeds will be ripe, at which time it should be cut up, in a dry time, and spread upon cloths in the sun to dry; then beat out the seeds, and preserve them dry in bags for use.

APIUM ANISUM DICTUM. See PIMPINELLA.

APIUM MACEDONICUM. See BUBON.

APIUM PYRENAICUM. See CRITHMUM.

APOCYNUM. Tourn. Inst. R. H. 91. Lin. Gen. Plant. 269. [*Ἀπόκυνον*, of *ἀπό* and *κυνός* a dog, because the antients believed this plant would kill dogs.] Dogbane.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five acute segments at the top; it hath but one petal, which is of the open bell-shape, cut into five parts at the brim, which turn backward; in the bottom of the flower are situated five nectariums, which are oval, and surround the germen: there are five stamina, scarce visible, which are crowned by oblong erect summits, which are bifid; in the center are two oval germen, supporting small styles, crowned with globular stigma, larger than the germen. The germen afterward become two long pointed capsules, opening in two valves, having one cell, which is filled with compressed seeds, lying over each other like tiles on a house, each being crowned with down.

This

This genus of plants is ranged in the second section of Linnæus's fifth class, entitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. APOCYNUM (*Androsæmi folium*) caule rectiusculo herbaceo foliis ovatis utrinque glabris cymis terminalibus. Lin. Sp. Plant. 213. *Dogbane with an erect herbaceous stalk, oval leaves, smooth on both sides, and terminated by a head of flowers.* Apocynum Canadense foliis androsæmi majoris. Mor. Hist. 3. p. 609.
2. APOCYNUM (*Cannabinum*) caule rectiusculo herbaceo foliis oblongis panniculis terminalibus. Lin. Sp. Plant. 213. *Dogbane with an erect herbaceous stalk, oblong leaves, and stalks terminated by flowers.* Apocynum Canadense maximum flore minimo herbaceo. Pluk. Alm. 35.
3. APOCYNUM (*Venetum*) caule rectiusculo herbaceo foliis ovato-lanceolatis. Prod. Leyd. 411. *Dogbane with an upright herbaceous stalk, and oval spear-shaped leaves.* Apocynum maritimum venetum salicis folio flore purpureo. Tourn. Inst. 92.
4. APOCYNUM (*Speciosissimum*) foliis ovatis petiolatis, superne glabris, floribus amplis pediculis longis hirsutis caule fruticoso. *Dogbane with oval leaves, which are smooth on their upper side, large flowers with long hairy foot-stalks, and a shrubby stalk.* Apocynum erectum fruticosum, flore luteo maximo & speciosissimo. Sloan. Cat. Jam. 89.
5. APOCYNUM (*Scandens*) foliis oblongo-cordatis rigidis floribus lateralibus, caule fruticoso volubili. *Dogbane with stiff, oblong, heart-shaped leaves, flowers growing on the sides of the stalk, and a shrubby twining stalk.* Apocynum scandens foliis citrii filiquis maculatis. Plum. Cat. 2.
6. APOCYNUM (*Frutescens*) caule erecto frutescente foliis lanceolato-ovalibus corollis acutis fauce villosis. Flor. Zeyl. 114. *Dogbane with an upright shrubby stalk, oval spear-shaped leaves, acute petals, and hairy jaws.* Apocynum caule erecto arboreo foliis ovatis acutis. Prod. Leyd. 412.
7. APOCYNUM (*Reticulatum*) caule volubili perenne foliis ovatis venosis. Prod. Leyd. 412. *Dogbane with a perennial twining stalk, and oval veined leaves.*
8. APOCYNUM (*Obliquum*) caule volubili foliis ovatis rigidis obliquis cymis lateralibus tubo floribus longissimo. *Dogbane with oval stiff leaves which are oblique, a twining stalk, and flowers growing from the side of the branches.* Apocynum scandens majus folio subrotundo. Sloan. Cat. Jam. 89.
9. APOCYNUM (*Nervosum*) caule fruticoso scandente foliis ovatis nervosis cymis lateralibus flore luteo magno tubo longissimo. *Dogbane with a climbing shrubby stalk, oval-veined leaves, and large flowers growing in bunches from the sides of the stalks, having very long tubes.*
10. APOCYNUM (*Cordatum*) foliis oblongo-cordatis, mucronatis sessilibus floribus lateralibus, caule scandente. *Dogbane with oblong heart-shaped leaves, which end in a point, flowers growing at the wings of the leaves, and a climbing stalk.* Apocynum scandens foliis oblongis acuminatis floribus amplis patulus & luteis. Houst. MSS. Fig. Pl. num. 8. pl. 44. f. s.
11. APOCYNUM (*Villosum*) foliis cordatis glabris floribus villosis lateralibus petiolis longioribus caule scandente. *Dogbane with smooth heart-shaped leaves, hairy flowers growing from the side of the branches, and a climbing stalk.* Apocynum scandens amplo flore villosa luteo filiquis tumidis angulosis. Houst. MSS. Fig. Pl. tab. 44. fig. 2.

The first sort grows naturally in North America. This hath a perennial root; the stalks rise about three feet high, grow upright, and are garnished with smooth oval leaves, growing opposite. These, as also the stalks, abound with a milky juice, which flows out when they are broken; the flowers are white, and collected in a kind of umbel, growing at the top of the stalks. The nectarii in the bottom, have a purplish cast; these flowers are seldom succeeded by pods which ripen in England, but the plant is propagated by parting the roots. It is hardy, so will thrive in the full ground, but the soil should be light or dry, otherwise the roots are apt to rot in winter. The best time to part the

roots is in March, before they begin to put out new stalks.

The second sort is a native of the same countries as the first; the roots of this sort creep far in the ground; so that when it is planted in a garden, it is apt to spread so much as to be troublesome. The stalks of this sort are brown, and grow about two feet high, garnished with oblong smooth leaves, set on by pairs, and abound with a milky juice as the former. Towards the upper part of the stalk, the flowers come out from the wings of the leaves, collected in small bunches, which are of an herbaceous white colour, and small, so make no great appearance, therefore are seldom admitted into gardens, except for the sake of variety. This is very hardy, and propagates too fast by its creeping roots. Both these sorts flower in July, and in autumn their stalks decay to the root.

The third sort grows upon a small island in the sea, near Venice, but is supposed to have been originally brought from some other country. There are two varieties of this, one with a purple, and the other with a white flower. The roots of this creep pretty much, by which it is propagated, for it scarce ever produces any seeds either in the gardens where it is cultivated, or at Venice, where it grows without care, as I have been informed by a very curious botanist, who resided many years at Venice, and constantly went to the spot several times in the season, to procure the seeds, if there had been any produced; but he assured me he never could find any pods formed on the plants. The stalks of this rise about two feet high, and are garnished with oval smooth leaves placed opposite; the flowers grow at the top of the stalks in small umbels, shaped like those of the former sorts, but are much larger, so that the sort with purple flowers makes a pretty appearance. It flowers in July and August. This sort will live in the open air, provided it is planted in a warm situation and a dry soil; for although the soil in which it grows wild near Venice, is moist, yet in this country the roots will rot in winter, when they are in a wet ground. The best time to remove and plant the roots is in spring, just before they begin to push out new stalks.

The fourth sort grows naturally in Jamaica, in the Savannas, from whence it had the title of Savanna Flower, by which it is chiefly known in that island. This sort rises three or four feet high, having woody stalks, which send out a few lateral branches, garnished with oval smooth leaves, placed by pairs opposite, of a shining green colour on their upper sides, but pale and veined underneath; the flowers are produced from the sides of the branches, upon long foot-stalks; there are commonly four or five buds at the end of each, but there is seldom more than one of them which comes to flower, the others withering soon. The flower is very large, having a long tube, which spreads open wide at the top, of a bright yellow, so make a fine appearance, especially in the places where the plants grow naturally, being most part of the year in flower. This plant is too tender to thrive in England without the assistance of a stove. It is propagated by seeds, which must be procured from Jamaica, for the plants do not perfect them in England, nor are many of the seeds which are brought from thence good, either from their being unskilfully gathered before they are ripe, or being put up moist, for few of them have succeeded. When the seeds are obtained, they should be sown in pots filled with light sandy earth, and plunged into a hot-bed of tanners bark. If the seeds are good, the plants will appear in a month or five weeks after, when they should be treated in the same manner as other tender plants from the same country, with this difference only, to be sparing in watering them, for these plants which abound with a milky juice, require very little wet. They must be constantly kept in the tan-bed in the stove, and as they advance in height, they will require larger pots, but there must be great care not to over-pot them; for unless their roots are confined, the plants will not thrive. The second year the

plants will flower, if they have been skilfully managed, when they will make a fine appearance in the stove; the usual time of their flowering in England, is in July and August, but the plants retain their leaves through the year, which, being of a beautiful green, look very well at all seasons.

The fifth sort was discovered by father Plumier, in some of the French islands in America, who made a drawing of the plant. It was afterwards found by the late Mr. Robert Millar, surgeon, growing plentifully near Carthagena, in New Spain, from whence he sent the seeds, which succeeded in several gardens. This plant hath twining stalks, by which it mounts to the tops of very tall trees, garnished with stiff, oblong, heart-shaped leaves, which are smooth, and of a shining green colour, being of the same thickness with those of the Citron-tree. The flowers are produced in small clusters from the sides of the branches, and are of an herbaceous colour, so do not make any great appearance. These appear in August and September, but are not succeeded by pods in this country.

The sixth sort grows naturally in India, Ceylon, and upon the coasts of Guinea, from whence I have received the seeds. This plant rises with a woody stem to the height of five or six feet, dividing into several branches, garnished with oblong, pointed, smooth leaves, of a shining green above, but pale underneath, placed by pairs opposite. From the wings of the leaves the flowers are produced in loose bunches. These are small, tubulous, and of a purple colour, but are never succeeded by pods in this country. It is a very tender plant, so must be constantly kept in a hot-house, and plunged in the tan-bed, otherwise it will not thrive in England; it may be propagated by cuttings during the summer months, but they should be laid to dry in the stove, three or four days before they are planted; for as the plants abound with a milky juice, so unless the ends of the cuttings where the wounds are made, are well dried and healed over before they are put into the ground, they are very subject to rot. This plant must be sparingly watered, especially in winter, and should be planted in light sandy earth.

The seventh sort grows naturally in India; I received seeds of this from Dr. Van Royen, professor of botany at Leyden. This plant hath a twining stalk, by which it rises to a considerable height, garnished with oblong leaves, which are much veined, and abound with a milky juice, which flows out whenever they are broken. This plant hath not yet produced flowers in England. It is tender, so requires to be constantly preserved in the stove, otherwise it will not thrive in this country.

The eighth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. William Houston. It hath a climbing stalk, which fastens to the neighbouring trees, and rises ten or twelve feet high. The leaves are oval, stiff, and oblique to the foot-stalk; the flowers are produced from the wings of the leaves, of a purplish colour, and have very long tubes, but spread open wide at the top. This doth not produce seeds in England, nor have I been able to propagate it, either by layers or cuttings. It is tender, so must constantly remain in the stove, and should have little water.

The ninth sort hath a climbing woody stalk, and rises to a considerable height, by the support of neighbouring trees. The leaves grow by pairs opposite; they are oval, ending in a sharp point, and have many transverse nerves from the midrib. The flowers come out from the wings of the leaves, each standing upon a separate long foot-stalk; they are large, of a bright yellow colour, with very long tubes, spreading open wide at the top; these are succeeded by long compressed pods, which have borders on one side filled with long channelled seeds, which are crowned with long plumes of soft down. This sort grows naturally at Carthagena, in New Spain, from whence I received the seeds. It is tender, so will not thrive in England, unless it is constantly preserved in the stove. This is

propagated by seeds, which must be procured from the country where it grows naturally, for the seeds do not ripen in this country. When the seeds are procured, they must be sown in pots, and plunged into a hot-bed; and when the plants come up, they should be treated in the same manner as hath been before directed for the fourth sort. It flowers in August and September in England, but in its natural country it flowers great part of the year.

The tenth and eleventh sorts were discovered at La Vera Cruz, in New Spain, by the late Dr. William Houston, who sent their seeds to England. These plants have both climbing stalks, by which they mount to the tops of the tallest trees. In England they have climbed over the plants in the stoves, and risen to upward of twenty feet high. The tenth sort has produced flowers in England several times, but the eleventh, which grows more luxuriantly than the other, never had any appearance of flowers. These are both propagated by seeds, which should be sown as the fourth sort, and the plants must be treated in the same manner afterward. All these species of Dogbane abound with a milky juice, which flows out from any part of their stalks or leaves when they are broken; and this is generally supposed to be hurtful, if taken inwardly, for it doth not raise blisters on the skin, as the juice of Spurge, and other acrid plants, so is not injurious unless inwardly taken. The pods of all the sorts are filled with seeds, which are, for the most part, compressed, and lie over each other (*imbricatum*) like tiles on a house: these have each a long plume, of a cottony down fastened to their crowns, by which, when the pods are ripe and open, the seeds are wafted by the wind to a considerable distance; so that in the countries where these plants naturally grow, they are some of the most troublesome weeds.

The down of these plants is in great esteem in France, for stuffing of easy chairs, making very light quilts, which are warm, and extremely light, so are very proper covering for persons afflicted with the gout, for the down is so extreme light and elastic that it occasions no weight. This the French call Delawad, and in the southern parts of France, where some of the sorts will thrive in the open air, and perfect their seeds, there are many plantations made of these plants for the sake of the down.

As many of these sorts grow plentifully in the uncultivated lands in Jamaica, this cottony down might be easily procured from thence in plenty, and might probably become a vendible commodity in England, which may turn to advantage, if once it becomes a fashionable sort of furniture, especially as the plants require no cultivation, the only trouble being to collect the down, which, in some of the sorts which have large pods, is produced in great quantity, so may be collected with little trouble.

The other sorts which have been ranged under this genus, are now referred to the following genera, to which the reader is desired to turn, for such of them as are not here enumerated, viz. *Asclepias*, *Cynanchum*, and *Periploca*.

APPLE-TREE. See *MALUS*.

APPLES of Love. See *LICOPERSICON* and *SOLANUM*.

APPLES (MAD). See *MELONGENA*.

APRICOT, or ABRICOT. See *ARMENIACA*.

AQUIFOLIUM. See *ILEX*.

AQUILEGIA [called also *Aquilina*, from *Aquila*, L. an eagle, because the flower resembles that bird].
Columbine.

The CHARACTERS are,

The flower hath no empalement, but is composed of five equal oval petals, which are plain, and spread open, within which are five equal nectarii, ranged alternately with the petals, each of the horns widening upward, the opening being oblique to the side as it ascends, and is fastened to the receptacle within, the lower part lengthening gradually into a long tube, hanging by a blunt incurved apex. It hath many awl-shaped stamens, which are crowned by oblong upright summits, with five oval germen, supporting

A Q U

porting awl-shaped styles, which are longer than the stamina, crowned by erect stigma; the germen afterwards become five cylindrical vessels, which stand upright, are parallel, pointed, and open in one cell, which are filled with oval shining seeds.

This genus of plants is ranged in the fifth section of Linnæus's thirteenth class, entitled Polyandria Pentagynia, the flowers having many stamina and five styles.

The SPECIES are,

1. *AQUILEGIA (Vulgaris) nectaris rectis petalo lanceolato brevioribus.* Lin. Sp. Plant. 533. *Columbine with upright nectariums shorter than its petal, which is spear-shaped.* *Aquilegia Sylvestris.* C. B. P. 144. *Wild Columbine.*
2. *AQUILEGIA (Alpina) nectariis rectis, petalis ovatis longioribus.* *Columbine with erect nectarii, and longer oval flower-leaves.* *Aquilegia montana magno flore.* C. B. P.
3. *AQUILEGIA (Inversa) nectariis incurvis.* Hort. Upsal. *Columbine with nectarii turned inward.* *Aquilegia flore pleno inverfo.* J. B. 485. *Columbine with a double inverted flower.*
4. *AQUILEGIA (Canadensis) nectariis rectis staminibus corollâ longioribus.* Hort. Upsal 153. *Columbine with straight nectarii, and stamina longer than the petals.* *Aquilegia pumila præcox Canadensis.* Cornut. Canad. 60. *Early dwarf Canada Columbine.*

The first sort is found growing wild in the woods in some parts of England; I have frequently gathered it in the woods, near Bexley, in Kent; and also between Maidstone and Rochester. The flowers of this are blue, the petals are short, and the nectarii are very prominent, in which it differs from the second, whose petals are longer, and the nectarii do not rise so high. This I found growing naturally near Ingleborough Hill, in Yorkshire. The flowers of this are much larger than those of the Garden Columbine, and the seeds which I sowed of this in the garden at Chelsea, produced the same species without the least variation.

The third is the Garden Columbine, of which there are great varieties, not only in the colour and fulness of their flowers, but also in their form. In some there are no visible nectarii, but in place of them a multiplicity of petals, so that the flowers are as double as those of the Larkspur. These are commonly called Rose Columbines; the colours of these are chefnut, blue, red, and white, and some are finely variegated with two colours.

There are others with sharp pointed petals, which expand in form of a star; of these there are single and double flowers, of the several colours as the former. From the different shape of these flowers, any person not well skilled in the culture of plants, would suppose they were distinct from the others; but having several years sown their seeds, which were collected with great care, I have found them always varying from one to the other: therefore I have not enumerated their varieties here, knowing they can never be preserved the same from seeds, however carefully they are saved: however, as the sorts with variegated flowers are esteemed the greatest beauties, so those persons, who are desirous to have them in perfection, should root out all those plants whose flowers are not well marked, or at least cut off their stems so soon as their flowers appear, leaving only the most beautiful to seed, that the farina of the plain flowers, may not impregnate the others, whereby the plants raised from their seeds may not be degenerated, of which too much care cannot be taken.

These plants are all raised by sowing the seeds, or parting the old roots, but the former method is chiefly practised; for the old roots are very apt to degenerate after they have blown two or three years, so as to become quite plain.

The seeds should be sown in a nursery-bed in August or September, for the seeds which are kept till spring seldom grow well, or at least remain in the ground a whole year. The spring following the plants will appear above ground, therefore should be kept clear from weeds, and if the season should be dry, they

A R A

should be refreshed with water, that they may gather strength.

In the middle or latter end of May, these plants will be strong enough to transplant; therefore some beds of good fresh undunged earth should be prepared, planting them therein at eight or nine inches distance every way, keeping them clear from weeds, and refreshing them with a little water, as they may require it.

In the following autumn, by which time the plants will have acquired strength enough to flower the summer following, the roots should be carefully taken up, and planted in the borders of the flower-garden; but where their roots are designed to be preserved in perfection, all their flower-stems should be cut off, as soon as the flowers are past, to prevent their degenerating by the commixture of the farina from other flowers.

But in order to be sure of having no single or bad flowers in the borders, you may suffer the plants to remain in the nursery-beds until they have blown; at which time you may put a stick by each root you fancy to preserve, or pull out all the single or bad coloured ones, and throw them away, cutting off all the flowers from your best roots as soon as they have shewn themselves, which will greatly add to the preserving them fair in their colours.

In order to keep up a succession of good flowers, fresh seeds should be sown every year; and if you can meet with a friend, at some distance, who is furnished with good flowers of this kind, it will be very advantageous to both parties, to exchange seeds once in two years, by which they will not be so apt to degenerate into plain colours.

In saving the seeds of the variegated columbines, great care should be taken not to suffer any plain flowers to remain for seed, there being generally some plain flowers intermixed with the striped ones on the same plant, and often in the same branches: these should be cut off, for if they are permitted to seed, or if their farina mix and impregnate the striped flowers, they will degenerate into plain colours; so that there cannot be too much care taken in saving the seeds, where the beauty of their flowers are regarded.

The Canada Columbine flowers almost a month before the other sorts; for which reason it is preserved in the gardens of the curious, though there is no great beauty in the flowers. There is another variety of this sort, with taller flower-stems, which flowers a little after the other, but do not differ, either in the shape of its flowers or leaves from this, so I conclude they are but one distinct species. The Canada Columbines flower in April, and their seeds ripen the beginning of August. The other sorts flower toward the end of May, and in cool seasons will continue to produce flowers till the middle of July, and their seeds ripen toward the middle or end of September, according as the season proves more or less favourable.

The first sort is that which is directed for medicinal use in the dispensaries, but at present is very rarely ordered.

A R A B I S. Lin. Gen. Plant. 732. Bastard Tower Mustard.

The CHARACTERS are,

The flower hath a four-leaved empalement, two of the opposite leaves being large, and the other two narrow; these fall off. The flower hath four petals in form of a cross, which spread open; at the bottom of each is situated a reflexed nectarium fixed to the empalement, and between these arise six upright stamina, two of which are no longer than the flower-cup, the other four are much longer: these are crowned with heart-shaped summits. In the center is situated a taper germen, which is as long as the stamina, having no style, but the obtuse stigma rests upon it. This afterward becomes a narrow, long, compressed pod opening lengthways, having two valves and a thin partition, between which is lodged a row of flat seeds.

T

This

This genus of plants is ranged in Linnæus's fifteenth class, entitled *Tetradynamia Siliquosa*: so called, because the flowers have four stamina longer than the other two, and the seeds growing in long pods.

The SPECIES are,

1. ARABIS (*Thaliana*) foliis petiolatis lanceolatis integerrimis. Vir. Cliff. 64. *Bastard Tower Mustard*, with whole spear-shaped leaves having foot-stalks. *Bursa pastoris similis filiquosa major*. C. B. P. 108.
2. ARABIS (*Alpina*) foliis amplexicaulibus dentatis. Hort. Cliff. 335. *Bastard Tower Mustard*, with indented leaves embracing the stalks. *Draba alba filiquosa repens*. C. B. P.
3. ARABIS (*Pendula*) foliis amplexicaulibus filiquis ancipitibus linearibus calycibus subpilosis. Hort. Upsal. 191. *Bastard Tower Mustard* with leaves embracing the stalks, narrow pods hanging two ways, and hairy flower-cups. *Turritis latifolia hirsuta filiquis pendulis*. Amman. Ruth. 58.
4. ARABIS (*Turrita*) foliis amplexicaulibus filiquis decurvis planis linearibus calycibus subrugosis. Hort. Upsal. 192. *Bastard Tower Mustard*, with narrow, plain, hanging pods, and rough flower-cups. *Leucoium hesperidis folio*. Tourn. Inst. 221. *Stock Gilliflower* with a leaf of *Dame's Violet*.
5. ARABIS (*Lyrata*) foliis glabris, radicalibus lyratis, caulinis linearibus. Flor. Virg. 99. *Bastard Tower Mustard* with smooth leaves, those at the root lyre-shaped, but on the stalks linear.
6. ARABIS (*Canadensis*) foliis caulinis lanceolatis dentatis glabris. Flor. Virg. 100. *Bastard Tower Mustard*, with spear-shaped, indented, smooth leaves. *Eruca Virginiana, bellidis majoris folio*. Pluk. Alm. 136.

The first sort is a low plant, seldom rising more than four or five inches high, sending out many short branches on every side, terminated by small white flowers growing alternately the most part of their length, each having four petals in form of a cross, which are succeeded by long slender pods filled with small round seeds. It grows naturally on sandy dry ground, in many parts of England.

The second sort grows naturally in Istria, from whence I received the seeds; it is also a native of the Alps, and many other mountainous countries. This is a perennial plant, which increases by its creeping roots, which run obliquely near the surface of the ground, and send down roots at every joint. The leaves are collected into heads, spreading circularly like those of the London Pride. These are oblong, whitish, and indented on their edges; out of these heads arise the flower-stalks, which grow near a foot high, garnished with leaves placed alternately, which are broader at their base than those which grow below, and closely embrace the stalks: the flowers grow in loose bunches on the top; these are white, and have leaves in form of a cross, which are succeeded by long flat pods, opening lengthways, having two cells, which are separated by an intermediate partition, each having one row of flat reddish seeds.

This is a very hardy plant, so will thrive in any situation. It produces seeds in plenty, but as it multiplies so fast by its creeping roots, few persons are at the trouble to sow the seeds. It flowers early in the spring, and having many stalks rising from one root, they make a pretty variety in cold situations, where many finer plants will not thrive, so may have place in rural plantations among shrubs, where they will thrive with very little care.

The third sort grows naturally in Siberia, from whence the seeds were brought to Petersburg. This is a perennial plant, which grows near a foot high; the leaves are broad, hairy, and indented on their edges; these closely embrace the stalks. The flowers grow alternately in loose spikes, and are of a dirty white colour. These are succeeded by long narrow pods, which are filled with flat brown seeds like the former, but the pods of this hang downwards two ways. It flowers early in spring, and perfects seeds very well, by which it may be propagated in plenty.

The fourth sort grows naturally in Hungary, Sicily,

and France. I have also found it growing wild upon some old walls at Cambridge and Ely, but the seeds might probably come out of the gardens where they were first planted. The plants of this kind, which grow on walls or ruins, continue much longer than those which are sown in gardens, where they seldom live longer than two years. The leaves of this sort are long, broad, hairy, and a little waved on their edges; of a pale colour, and spread near the ground: from the center of these come out the stalks, which rise about a foot and a half high, having several leaves growing alternately, which closely embrace them. Toward the top of the stalks, they divide into several small branches, which are terminated by long loose spikes of flowers, of a dirty white colour, each having four petals placed in form of a cross. After the flowers are past, the germen becomes long flat pods, which turn backward at their extremity and open lengthways, having two rows of flat-bordered seeds, of a dark brown colour, separated by a thin intermediate partition.

This sort is easily propagated by seeds, which should be sown in the autumn; for those which are sown in the spring frequently miscarry, or lie in the ground a whole year before they grow. When the plants are strong enough to remove, they may be transplanted into a shady border, or in rural plantations, where no other care will be necessary, but to prevent their being overgrown by weeds. The plants flower in May, and their seeds ripen in July. There is little beauty in this plant, yet many persons preserve it in their gardens to make a variety.

The fifth sort is annual, it grows naturally in North America; the leaves near the root are lyre-shaped, but those on the flower-stalks are linear, placed alternately; both are smooth; the flower-stalks rise near a foot high, and are terminated by white flowers, which are succeeded by slender pods.

The sixth sort was brought from Virginia; this is a biennial plant, whose lower leaves spread on the ground, these are deeply indented on their sides; the flower-stalks rise a foot high, sustaining several yellow flowers placed scatteringly at the top, which are succeeded by pretty long flat pods, filled with seeds.

The two last mentioned sorts have little beauty to recommend them, nor are their virtues known, therefore they are rarely admitted into any gardens except for variety. They are easily propagated by seeds, which if permitted to scatter on the ground, will produce plants in plenty on any soil, or in any situation.

ARACHIS, Earth, or Ground Nut.

The CHARACTERS are,

The empalement of the flower opens in two parts, the upper being cut into three at the extremity, the under one is hollow ending in a point, and longer than the other. The flower is of the butterfly kind, having four petals; the standard is large, roundish, and plain; the wings are open and shorter than the standard, the keel is little longer than the empalement, and turns back. The flower hath ten stamina, nine of which coalesce, and the upper one stands off; these are no longer than the keel, crowned by round summits. In the center is situated an oblong germen, supporting an awl-shaped style, crowned by a single stigma. The germen afterward turns to an oblong pod, containing two or three oblong blunt seeds.

This genus of plants is ranged in Linnæus's seventeenth class, entitled *Diadelphia Decandria*, from the flowers having ten stamina, which are in two bodies.

We have but one SPECIES of this plant, viz.

ARACHIS (*Hypogæa*). Lin. Hort. Cliff. 353. *Earth or Ground Nut*. *Arachidna quadrifolia villosa flore luteo*. Plum. Nov. Gen. 49.

The native country of this plant I believe is Africa, though at present, all the settlements in America abound with it; but many persons who have resided in that country affirm, they were originally brought by the slaves from Africa there, where they have been spread all over the settlements.

It multiplies very fast in a warm country, but being impatient of cold, it cannot be propagated in the open air

air in England; therefore whoever has an inclination to cultivate this plant, must plant the seeds in a hot-bed in the spring of the year, keeping the glasses over the plants till the middle or end of June; after which time, if the weather prove warm, they may be exposed to the open air by degrees. The branches of this plant trail upon the ground, and the flowers (which are yellow) are produced single upon long foot-stalks; and as soon as the flower begins to decay, the germen is thrust under ground, where the pod is formed and ripened; so that unless the ground is opened, they never appear: the negroes kept this a secret among themselves, therefore could supply themselves with these nuts unknown to their masters. The roots of these plants are annual, but the nuts or seeds sufficiently stock the ground in a warm country, where they are not very carefully taken up. In South Carolina there is great plenty of these nuts, which the inhabitants roast, and make use of as chocolate.

ARALIA, Berry-bearing Angelica.

The CHARACTERS are,

It is an umbelliferous plant with a globular umbel, having a small involucre; the empalement of the flower is small, indented in five parts, and rests upon the germen. The flower hath five oval petals, which are reflexed; it hath five awl-shaped stamina crowned by roundish summits; the round germen below the empalement supports five short styles, each of which is crowned by a single stigma. The germen afterward turns to a roundish channelled berry, having five cells, each containing one oblong hard seed.

This genus of plants is ranged in the fifth section of Linnæus's fifth class, entitled Pentandria Pentagynia, the flowers having five stamina and five styles.

The SPECIES are,

1. ARALIA (*Racemosa*) caule folioso herbaceo lævi. Hort. Upsal. 70. *Berry-bearing Angelica, with an herbaceous leafy stalk.* Aralia Canadensis. Tourn. Inst. R. H. 300.
2. ARALIA (*Nudicaulis*) caule nudo foliis ternatis. Hort. Cliff. 113. *Berry-bearing Angelica with a naked stalk.* Aralia caule nudo radice repente. Cold. Noveb. 66.
3. ARALIA (*Spinosa*) arborefcens caule foliolisque aculeata. Vir. Cliff. 26. *Tree Berry-bearing Angelica, whose stalk and leaves are prickly.* Aralia arborefcens spinosa. Vaill. Serm. *Angelica-tree*, vulgò.

The first sort is pretty common in many gardens near London, but the second is at present more rarely met with. Both these plants grow naturally in North America, from whence their seeds were brought to Europe. They are perennial plants, whose stalks decay in autumn, and new ones arise from their roots in the spring. The first grows three or four feet high, and divides into many irregular branches, garnished with ramose leaves, placed alternately; at the wings of these the flower-stalks are produced, which are terminated by round umbels of small four-leaved flowers, of a whitish colour; these are succeeded by round channelled berries, which when ripe, are black. This flowers in July, and the seeds ripen in October.

The second sort rises to near the same height as the former; the leaves of this have two trifoliate large lobes, which are sawed on their edges. The flower-stalks arise between these immediately from the root, being naked, and are terminated by round umbels of flowers, in shape and colour like the first; these are succeeded by berries, which are smaller than those of the other. This flowers toward the end of July, and the seeds ripen late in the autumn. The roots of this sort were formerly brought over and sold for Sarsaparilla, and at this time several of the inhabitants of Canada make use of it as such, but it is very different from the true sort.

Both these sorts are easily propagated by seeds, which are generally produced in plenty. These should be sown in the autumn soon after they are ripe, for those which are sown in the spring, never grow the same year, so that a whole season is gained by the sowing in autumn. When the plants appear, they must be kept clean from weeds during the summer; and in the autumn following, when their leaves decay, the

roots may be taken up, and transplanted where they are to remain. They are very hardy plants, so may be planted in any situation; and as they grow naturally in woods, so they may be planted in wilderness quarters, under trees, where, although they have no great beauty, yet they will add to the variety.

These two sorts may also be propagated by parting of their roots; the best time for doing this is in the autumn, soon after their leaves decay. These should be planted pretty far asunder, for their roots spread to a considerable distance, where they are left undisturbed for some years.

The third sort rises with a woody stem to the height of eight or ten feet, dividing into several branches, garnished with branching leaves, which are compounded of many divaricated wings; the lobes of which are oblong, and the ribs of the leaves, as also the branches and stems of the plants, are armed with strong crooked spines, which renders the places very difficult to pass through where they grow in plenty. The flowers of this sort are produced in large loose umbels, at the extremity of the branches, and are of an herbaceous colour, so make no great figure, but the plants are preserved in most of the curious gardens in England. It flowers in August, but the seeds do not ripen in this country.

This is propagated by seeds, which are easily procured from North America; but as they seldom arrive here till toward the spring, so the plants never come up the first year: therefore when the seeds arrive, they should be sown in pots, filled with light earth, and placed in a shady situation, where they may remain until the next autumn, being careful to weed the pots constantly; otherwise if weeds are permitted to grow till they are large, they cannot be taken out, without drawing up the seeds with their roots. In the autumn, the pots should be plunged either into an old bed of tan, or in a warm border under the shelter of a hedge or wall; and if the winter proves severe, it will be proper to cover the pots with straw or Pease-haulm, to prevent the frost from penetrating deep into the ground. In March the pots should be plunged into a moderate hot-bed, which will bring up the plants early, so that they will have more time to get strength before the following winter. When the plants come up, they should be frequently refreshed with water, and constantly kept clean from weeds: in May they should be inured to the open air, and when they are removed out of the bed, they should have a shady situation. These plants should not be disturbed the first season, but as they are often injured by frost when young, so in October the pots should be placed under a frame, where they may be screened from hard frosts, but in mild weather should be constantly opened to enjoy the free air. The leaves of these plants fall away in the autumn, so that some persons have supposed them dead, and have thrown them out of the pots, which every one should be cautioned against. In the spring, before the plants begin to push, they should be carefully shaken out of the pots, and separated; part of them should be planted singly into small pots, and the other may be planted in a bed of light earth in a warm situation. If those which are planted in the small pots are plunged in a moderate hot-bed, it will greatly forward their growth; but they must be early inured to bear the open air, otherwise they will draw up weak. In the following summer they must have a shady situation, and the next winter should be sheltered again; the spring following they may be shaken out of the pots, and planted where they are designed to remain. Those plants which were planted in the bed, will require protection from the frost the first winter; therefore if the surface of the ground is covered with old tanners bark, it will prevent the frost from penetrating to their roots; and if in hard frosts, some straw, Pease-haulm, or any light covering is laid over the bed, it will secure their stems from being injured. The plants in the bed may remain there two years; by which time they will be strong enough to transplant

A R B

to the places where they are designed to grow. As these plants do not come out very early in the spring, so they often continue growing pretty late in the autumn, which causes the extreme parts of their shoots to be very tender, whereby they often suffer from the early frosts in autumn, which frequently kill the upper parts of the shoots; but as their woody stems are seldom injured, so they put out new branches below: and if in very severe winters the stems are destroyed, yet the roots will remain, and put out new ones the following summer, therefore they should not be destroyed.

This plant may also be propagated by its roots, for as they spread far in the ground, so if they are laid open, and some of the strongest are separated from the plant and left in the ground, they will put out new stems and make new plants. Or if part of the roots are taken off and planted on a moderate hot-bed, they will push out stems in plenty, so may be increased with ease.

ARBOR, a tree, is defined to be a gemmiparous plant, with a single trunk or stem, abounding with shoots. This is the only definition which conveys an idea whereby to distinguish a tree from a shrub, which is a gemmiparous plant, with many stems or trunks.

ARBOR CAMPHORIFERA. See **LAURUS**.

ARBOR CORAL. See **ERYTHRINA**.

ARBOR JUDÆ. See **CERCIS**.

ARBOREOUS [*Arboreus*, Lat. of, or belonging to, or of the nature of, trees.] An epithet which botanists apply to those funguses, or mosses which grow on trees, in distinction from those that grow on the ground; as *Agaric*, *Jews-ear*, &c.

ARBOURS [*Arborea*, of *Arbor*, Lat. a tree.] These were formerly in greater esteem with us than at present; few gardens were without covered arbours, and shady seats; but of late they have been much rejected, and that not without good reason; for besides the great expence in their first erecting, they were a continual charge keeping repaired; for the wet soaking through the leaves of the trees to the wood-work, was, by the continual shade, and for the want of free air, detained so long as to rot the wood (which, if wholly exposed to the weather, would have lasted seven or eight) in two or three years; beside, the seats are continually damp, and unhealthy: for which reason, covered seats or alcoves, are every where, at this time, preferred to them.

Arbours are generally made of lattice-work, either in wood or iron, and covered with Elms, Limes, Hornbeam; or with Creepers, as *Honeysuckles*, *Jasmines*, or *Passion-flowers*; either of which will answer the purpose very well, if rightly managed.

ARBUTUS, the Strawberry-tree.

The **CHARACTERS** are,

The flower hath a small, obtuse, permanent empalement, which is cut into five parts, upon which the germen sits. The flower is of one leaf, shaped like a pitcher, and divided into five parts at the brim, which turn backward. It hath ten short stamina, which are joined at the bottom to the flower leaf; these are crowned with bifid summits. At the bottom of the flower is situated the globular germen, supporting a cylindrical style, crowned by a thick blunt stigma. After the flower is past, the germen becomes an oval or round berry, having five cells, which are filled with hard seeds.

This genus of plants is ranged in the tenth class of *Linnaeus*, entitled *Decandria Monogynia*, from the flowers having ten stamina and one style.

The **SPECIES** are,

1. **ARBUTUS** (*Unedo*) foliis glabris serratis, baccis polyspermis, caule erecto arboreo. *Strawberry-tree with smooth sawed leaves, berries having many seeds, and an upright trunk.* *Arbutus folio serrato.* C. B. P. 460.
2. **ARBUTUS** (*Andrachne*) foliis glabris integerrimis, baccis polyspermis caule erecto arboreo. *Strawberry-tree with smooth entire leaves, berries full of seeds, and an erect woody stem.* *Arbutus folio non serrato.* C. B. P. 46. *Andrachne Theophrasti.* Clus. Hist. 48. called *Andrachne*.

A R B

3. **ARBUTUS** (*Acadiensis*) caulibus procumbentibus foliis ovatis subserratis floribus sparsis baccis polyspermis. *Lin. Sp. Plant.* 395. *Arbutus with trailing stalks, oval leaves, somewhat indented, flowers growing loosely, and many seeds.* *Vitis idæa Acadiensis foliis Alaterni.* Tourn. Inst.

4. **ARBUTUS** (*Alpina*) caulibus procumbentibus foliis rugosis serratis. *Flor. Lap.* 161. *Arbutus with trailing stalks and rough sawed leaves.* *Vitis idæa foliis oblongis albicantibus.* C. B. P. 470.

5. **ARBUTUS** caulibus procumbentibus foliis integerrimis. *Flor. Lap.* 162. *Arbutus with trailing stalks and entire leaves.*

6. **ARBUTUS** (*Uva Ursi*) caulibus diffusis, foliis emarginatis. *Arbutus with diffused stalks and indented leaves.* *Uva ursi.* Clus. Hist. 1. p. 63. *Bear Berry.*

The first sort grows naturally in Italy, Spain, and also in Ireland, and is now very common in the English gardens. Of this sort there are the following varieties, viz. one with an oblong flower and oval fruit; another with a double flower, and a third with red flowers; but these being only seminal varieties, I have not mentioned them as species; though for the sake of the curious, I shall give a farther account of them.

The second sort grows naturally in the east, particularly about *Magnesia*, where it is so plenty, as to be the principal fuel used by the inhabitants of the country. This grows to a middle sized tree; the branches are irregular, and are garnished with large oval leaves, somewhat like those of the *Bay-tree*, but not quite so long; these are smooth and entire, having no serratures on their edges; the flowers are shaped like those of the common *Arbutus*, but grow thinly on the branches. The fruit is oval, and of the same colour and consistence with the common sort, but the seeds of this are flat, whereas those of the common sort are pointed and angular. *Tournefort* enumerates three other varieties of this tree, which he observed in the *Levant*, one with sawed leaves, which is now in many English gardens, and passes for the *Andrachne*: another with a large oblong fruit, and a third with large compressed fruit: but it is doubtful if they are not accidental varieties, which have been produced from seeds of the first.

The common *Strawberry-tree* is too well known to require any description of it here, being at present in most of the English gardens, and is one of the greatest ornaments to them in the months of October and November, that being the season when the trees are in flower, and the fruit of the former year is ripe, for the fruit is a whole year growing to perfection; so that the fruit which is produced from the flowers of one year, do not ripen till the blossoms of the succeeding year are fully blown; so that when there is plenty of fruit and flowers upon the trees, they make a goodly appearance, and at a season when most other trees are past their beauty.

Those trees which have large oval fruit, make the greatest figure, the flowers of this being larger, and oblong. The sort with double flowers is a curiosity, but as the flowers have only two orders of leaves, so they make no great appearance; nor do the trees produce fruit in any plenty, therefore the other is more preferable. The sort with red flowers makes a pretty variety, when intermixed with the other; for the outside of them are of a fine red colour at their first appearance, and afterward they change to purple before they fall off. The fruit of this is the same with the common sort. All these varieties are preserved, by inarching or grafting them upon the common *Arbutus*, for the seeds of either do not produce the same kind; though from the seeds of the oval fruit, there is generally many more of the same produced, than from the seeds of the common sort.

The best method to propagate the *Arbutus* is from seeds; therefore when the fruit is perfectly ripe, it should be gathered and mixed with dry sand, to preserve them till the time for sowing them; the surest method of raising the plants, is to sow the seeds in pots,

A R B

pots, which should be plunged into an old bed of tanners bark, which has lost its heat, covering the bed with glassies, &c. to keep out frost; this should be done in December, if the seeds are good, and as the spring advances, the pots are refreshed with water, the plants will come up the beginning of April, when they should be frequently but sparingly watered, and constantly kept clean from weeds.

As the summer advances, if the plants are shaded in the heat of the day, it will greatly promote their growth; but in warm weather they must be open all night to receive the dew, so should only be covered in the middle of the day: with this management, the plants will rise to the height of five or six inches the first summer. The beginning of October, these plants may be shaken out of the pots, and their roots carefully separated, planting them singly in small pots filled with light earth; then plunge the pots into an old bed of tanners bark, under a common frame, observing to shade them from the sun in the middle of the day, and to give them water as they may require: in this bed the pots should remain during the winter, observing to expose the plants to the open air, at all times when the weather is favourable; but in frosty weather they must be covered, otherwise they will be in danger if the season proves severe. The spring following the plants may be removed to a very gentle hot-bed, which will require no other covering but mats. This will enable them to make strong shoots early in the summer, whereby they will be in a better condition to bear the cold of the succeeding winter: in this bed the plants may continue most part of the summer, for if the pots are taken out and set upon the ground, the smallness of their size will occasion the earth in them to dry so fast, that watering will scarcely preserve the plants alive; but if they are kept growing all the summer, they will be more than a foot high by the next autumn: but it will be advisable to screen them from the frost during their continuance in pots, by plunging them into the ground in a warm place, and covering them with mats in bad weather.

When the plants are grown to be two or three feet high, you may shake them out of the pots, and plant them in the open ground in the places where they are to remain; but this should be done in April, that they may have taken good root before the winter, which would be apt to damage them if newly planted; and as all the earth about their roots may be thus preserved, there will be no fear of succeeding at this season.

These plants are tolerably hardy, and are seldom hurt, except in extreme hard winters, which many times kill the young and tender branches, but rarely destroy the roots; therefore, however dead they may appear after a hard winter, yet I would advise the letting them remain till the succeeding summer has sufficiently demonstrated what are living and what are dead; for the winters anno 1728-9, and 1739-40, gave us great reason to believe most of the trees of this kind were destroyed; and many people were so hasty, as to dig up or cut down, many of their trees; whereas all those people who had patience to let them remain, found that scarce one in five hundred failed to come out again the next summer, and many of them made handsome plants that season.

This tree delights in a moist soil, for when they are planted in dry ground, they seldom produce much fruit: the flowers of this tree being produced in autumn, if the winter proves severe, are generally destroyed, which has occasioned their producing very little fruit in England for several years: therefore, in order to obtain fruit, the trees should be placed in a warm situation; and where the ground is not naturally moist, there should be a good quantity of loam and rotten neat's dung laid about their roots; and if the spring should prove dry, they must be plentifully watered, in order to have plenty of fruit.

The very best season for transplanting of the *Arbutus* is in September, at which time the blossoms are be-

A R C

ginning to appear; and at that season, if it should prove very dry and they are kept moist, they will take root very soon; but toward the beginning of November, their roots should be well covered with mulch, to keep out the frost.

The third sort grows naturally in Acadia, and other northern parts of America, upon swampy land, which is frequently overflowed with water; this is a low bushy shrub, with slender trailing branches, which are garnished with oval leaves, a little sawed on their edges; the flowers come out from the wings of the leaves, growing in thin loose bunches. The fruit of this sort is never produced in England, and it is with great difficulty the plants are kept alive here.

The fourth sort grows naturally on the Alps, and the Helvetian mountains. This never rises high, but sends out from the root many slender branches, which trail upon the ground, garnished with oblong rough leaves, of a pale green colour; the flowers are produced from the wings of the leaves, upon long slender foot-stalks, and are succeeded by berries about the size of the common black Cherry, which are first green, afterward red, and when ripe they are black. These are of a pleasant taste, so are frequently eaten by the inhabitants of those countries where they grow naturally. This is also a very difficult plant to keep alive in gardens, for it is an inhabitant of bogs, growing among moss, where the ground is never dry.

The fifth sort grows naturally upon the mountains in Spain, and in most of the northern parts of Europe. The branches of this trail on the ground, which are closely garnished with smooth thick leaves of an oval form, placed alternately; the flowers are produced in small bunches toward the extremity of the branches, which are shaped like those of the common sort, but are smaller; and are succeeded by berries, of the same size with those of the former sort, which are red when ripe.

There are few of these plants in the English gardens, for as they are inhabitants of very cold countries, where they are covered with snow all the winter, and growing upon bogs among moss, so when they are brought into a garden, they seldom continue long, nor do they thrive with the utmost care; for in places where artificial bogs have been contrived to receive these plants, they have been preserved two or three years, and then have perished; so that unless the place where they are planted is naturally boggy, there is little hopes of their succeeding long.

The sixth sort grows naturally upon Mount Cenis in Italy, and upon some mountains in Spain; this hath woody stalks which rise two or three feet high, dividing into many diffused branches, closely garnished with roundish fleshy leaves, which are indented at the top; the flowers are produced in a racemus toward the end of the branches, which are shaped like those of the Strawberry-tree, of an herbaceous colour, striped with purple. The plants of this kind are very rare in England, nor is this sort much known among botanists, most of whom have supposed the fifth to be the sort mentioned by Clusius, in which they are greatly mistaken.

The *Adrachne* is at present very rare in England; this may be propagated in the same manner as hath been directed for the common *Arbutus*, but as there are no plants in this country which produce fruit at present, the seeds must be procured from the Levant, where they may be had in plenty. As the leaves of this tree are larger than those of the common *Arbutus*, the trees make a finer appearance, therefore deserve our care to cultivate them, especially as they will bear the open air when the plants are become woody; for while they are young, they are impatient of much frost, therefore should be preserved in pots three or four years, till they have obtained strength, and may then be planted in a warm situation and on a dry soil, for this sort will not thrive in wet ground.

ARCTIUM. Lin. Gen. 830. Lappa. Tourn. Inst. R. H. Burdock.

U

The

The CHARACTERS are,

The empalement of the flower is scaly, each scale ending in a long thorn which is reflexed at the point. The flower is composed of many florets, which are tubulous, uniform, and of one leaf. The tube is long and slender, cut into five narrow segments at the top: these have each five short slender stamina, which are crowned by cylindrical summits. The germen is situated at the bottom of the tube, having a hairy tip, supporting a long slender style, crowned by a bifid reflexed stigma; the germen afterward becomes a single, pyramidal, angular seed, crowned with down.

This genus of plants is ranged in the first section of Linnæus's seventeenth class, entitled Syngenesia Polygamia Æqualis, there being an equal number of female and hermaphrodite flowers included in one common empalement.

The SPECIES are,

1. ARCTIUM (*Lappa*) foliis cordatis inermibus petiolatis capitulis majoribus sparsis. *Burdock with heart-shaped leaves without prickles, having foot-stalks, and large heads growing scatteringly.*
2. ARCTIUM (*Personata*) foliis cordatis inermibus, capitulis minoribus compactis. *Burdock with heart-shaped leaves without spines, and small heads growing close together.*
3. ARCTIUM (*Tomentosus*) foliis cordatis inermibus, capitulis tomento-reticulatis. *Burdock with heart-shaped leaves without spines, and woolly netted leaves.*

The two first sorts are common weeds, growing on the sides of roads and foot-paths in most parts of England, and are not admitted into gardens. The first is ordered for medicinal use by the college of physicians, therefore I have inserted it here: the second is by many supposed to be only a variety of the first, but I have for several years sown the seeds of both sorts in the Chelsea garden, where they have constantly retained their difference, so may be allowed to be distinct species. The first is titled by Caspar Bauhin, *Lappa major*, five *Arctium Dioscorides*. Pin. 192. *Greater Burdock*, or *Arctium of Dioscorides*. The second is titled by Vaillant, *Lappa vulgaris capitulo minore*. Act. Par. 1718. *Common Burdock with a small head.*

The third sort is not a native of England, but grows naturally on the Apennine mountains. The leaves of this are like those of the common sort, but are whiter on their under side; the heads are more compact, and the florets are of a bright red colour; but the greatest difference is in their empalements, which in this sort are beautifully netted with a fine down all over. This is also supposed to be only a variety of the common sort, but I have cultivated it above forty years, during which time it has never varied, so that it is certainly a distinct species. This is by Caspar Bauhin titled, *Lappa major montana capitulis tomentosus*. Pin. 198. *Greater Mountain Burdock with woolly heads.*

As these plants are seldom admitted into gardens, it is needless to say any thing of their culture; but where they are troublesome weeds, it may not be amiss to mention, that their roots last but two years, so may be destroyed with less trouble than such as have perennial roots; for if they are cut up before they seed, in two or three years they may be entirely rooted out; for the plants which come up from seed, do not flower till the second year, and when the seeds are perfected their roots decay.

ARCTOTIS. This hath been usually known under the title of Anemonospermus, from the resemblance the seeds of these plants have to that of the Anemone.

The CHARACTERS are,

The common empalement is roundish and scaly, those on the lower part are loose and awl-shaped, the middle oval, and those on the top concave. The flower is composed of many female florets which are ranged on the border; these have one side stretched out like a tongue, which are called the rays, having an oval four-cornered germen situated in their center, crowned with down, supporting a slender style, crowned by two oval stigma; the germen afterward becomes a single roundish seed, covered with a soft down.

The middle or disk of the flower is composed of hermaphrodite florets, which are funnel-shaped, and divided at the top into five parts, which are reflexed; these have five stamina, crowned by short summits; in the center is placed a small germen, supporting a cylindrical style with a single stigma. These flowers are abortive.

This genus of plants is ranged in the fourth section of Linnæus's seventeenth class, entitled Syngenesia Polygamia Necessaria, the flowers of this section being composed of female and hermaphrodite florets; in some species the florets in the disk are fertile, and in others they are sterile.

The SPECIES are,

1. ARCTOTIS (*Trifidis*) flosculis radiantibus vicenis tripartitis. Lin. Sp. 1306. *Arctotis with the rays of the flower composed of florets cut into three segments.* Anemonospermus Afra, foliis & facie taraxaci incanis. Breyn. Prod. t. 15.
2. ARCTOTIS (*Angustifolia*) flosculis radiantibus fertilibus, foliis lanceolatis integris dentatis, Lin. Sp. 1306. *Arctotis whose florets in the rays are fertile, and spear-shaped, entire, indented leaves.* Anemonospermus Afra, folio serrato rigido flore intus sulphureo extus puniceo. Boerh. Ind. Alt. 1. p. 1. 100.
3. ARCTOTIS (*Aspera*) flosculis radiantibus fertilibus, foliis pinnato-sinuatis villosis laciniis oblongis dentatis. Lin. Sp. 1307. *Arctotis whose rays of the flower are fertile and woolly, with sinuated, oblong, indented leaves.* Anemonospermus Afra, folio Jacobææ tenuiter laciniato flore aurantio pulcherrimo. Boerh. Ind. Alt. 1. p. 100.
4. ARCTOTIS (*Calendula*) flosculis radiantibus sterilibus duodenis subintegris, foliis lyratis nigro denticulatis. Lin. Sp. 1306. *Arctotis whose rays of the flower are sterile and intire, and the leaves are lyre-shaped and indented.* Anemonospermus Africana Jacobææ maritimæ foliis flore sulphureo. Com. Rar. 36.
5. ARCTOTIS (*Plantaginea*) flosculis radiantibus fertilibus, foliis lanceolato-ovatis nervosis decurrentibus amplexicaulis. Lin. Sp. 1306. *Arctotis whose rays of the flower are fertile, and oval, spear-shaped, nervous, running leaves embracing the stalks.* Anemonospermus Afra, folio plantaginis, florum radiis intus aureis extus puniceis. Boerh. Ind. 1. p. 100.
6. ARCTOTIS (*Acaulis*) pedunculis radicalibus, foliis lyratis. Lin. Sp. 1306. *Arctotis whose foot-stalks arise from the root, and the leaves are lyre-shaped.* Anemonospermus Africana, folio plantiginis flore sulphureo. Com. Rar. 35.
7. ARCTOTIS foliis pinnato-laciniatis crispis caule ramoso fruticoso. *Arctotis with winged, jagged, curled leaves, and a branching shrubby stalk.* Anemonospermus Africana foliis Cardui benedicti florum radiis intus albicantibus. Hort. Amst. 2. 45.
8. ARCTOTIS (*Paleacea*) flosculis radiantibus sterilibus, paleis flosculos disci æquantibus, foliis pinnatis linearibus. Amœn. Acad. 6. Afr. 84. *Arctotis whose rays of the flower are barren, the scales of the flowers in the disk equal, and linear winged leaves.* After foliis integris angustis, flore magno luteo. Burm. Afr. 176.

These plants are natives of the country about the Cape of Good Hope, from whence they have been brought to some curious gardens.

The first sort here mentioned is an annual plant, which may be sown upon a warm border of light earth in the open air, in the middle of April, where they are designed to remain; these flower in August, and if the season proves favourable, they will perfect seeds very well, and the plants will grow much stronger than those raised upon a hot-bed; but, as in cold seasons these may fail to perfect their seeds, it will be a secure method to raise some upon the hot-bed, which never fails to perfect seeds, provided they are not treated too tenderly.

The second, third, fourth, and seventh sorts, grow to the height of four or five feet, sending forth many branches; therefore will require to be frequently pruned, to keep them in tolerable order, especially the seventh, which sends forth strong rambling shoots, when their roots are not much confined in the pots, but more so when they are duly watered.

These

A R C

These are seldom destitute of flowers the whole year, unless the winter is severe, which renders them more valuable than those which flower at one season only; for all those plants which flower in the winter-season, make a fine variety in the green-house; and when the plants are set abroad in summer, their flowers being at that season produced in greater plenty, they add to the beauty of a garden.

The shrubby sorts are propagated by planting cuttings in a bed of light fresh earth, in any of the summer months, observing to shade them from the heat of the sun until they have taken root, as also to refresh them often with water; and in six weeks after planting, they will be rooted sufficiently, at which time they should be transplanted into pots filled with fresh earth, setting the pots in a shady place until the plants are new rooted; after which time they should be placed in the open air until the latter end of October, or later, according as the weather is favourable, when they must be removed into the green-house, where they should be placed as near the window as possible, that they may have a good quantity of free air at all times, when the weather is mild; nor should they be over-hung by other plants, which would occasion them to take a mouldiness, and rot; they must also be frequently refreshed with water, giving it them plentifully in mild weather, otherwise their leaves and branches will hang and wither; in summer they can scarce have too much water given them. They will also require to be shifted into other pots two or three times at least every summer, and the pots should be frequently removed, to prevent the plants from striking their roots through the holes of the pots into the ground, which they are very apt to do, then they will shoot very vigorously; but when these roots are torn off, by removing the pots, the plants are often killed.

All these plants should be frequently renewed by cuttings, because the old plants are subject to decay in winter; therefore if young plants are not annually raised, the species may soon be lost.

If the green-house in which these plants are placed in winter is subject to damps, it will be very difficult to preserve some of the sorts; for when the windows are kept close, the tender parts of their shoots are very subject to a mouldiness, which will soon cause the plants to decay, if it is not constantly cleaned off, and free air admitted to dry off the damps.

ARCUATION [from *arcuo*, Lat. to bend or bow like an arch;] the method of raising trees by layers.

The first thing that is to be done, is, to procure strong mother plants, which are usually called stools. It is no matter whether the trees be crooked, or otherwise deformed. They are to be planted in a border six feet wide, and in a strait line six feet asunder.

The border must be well trenched, or dug, and cleared from all roots, clods, stones, or any other obstructions. These trunks or stools being planted in this trench, will throw out a great many shoots according to their strength, which may be laid about the Michaelmas following: in order to this, the ground round each stool should be carefully dug, breaking the clods and picking out the stones as before. Then the shoots should be bent down in arches, and put into the ground about three inches deep; and to keep them in this situation, each should have a forked stick drove into the ground over the part of the shoot immersed, turning the extremity of each shoot upward.

When the branches are thus laid round the stool, and pegged fast down, the branches, or shoots, will be covered all over, except the very top. Some persons give the branches a twist, in order to make them take root the sooner. Others slit such of the shoots as are not apt to take root without, in the same manner as is practised in laying of Carnations, which is generally a sure way; and if they are afterward mulched, it will be of use to keep out the frost in winter, and also to keep the ground moist the following spring and summer.

A R G

About the end of September following they may be opened and examined, to see if they have taken root or not, which it is very probable they will have done; but if not, they must be let alone, to lie till the next autumn, when they are to be taken up, and planted in the nursery.

This may be done to the Dutch, Witch, and English Elms; the Abele, Lime, Alder, Platanus, and many sorts of evergreen trees and flowering shrubs.

AREA is the internal capacity or content of any given boundary or limits, of what figure or shape soever it be.

ARGEMONE [so called from *Ἀργεμῶνα*, a disease in the eye, which this plant is said to cure; it is also called the Infernal Fig, because the capsule pretty much resembles a Fig, and from its asperity,] Prickly Poppy.

The CHARACTERS are,

The flower hath a three-leaved empalement, which falls off; it hath five roundish petals, which spread open, and are larger than the empalement; in the center is situated an oval five-cornered germen, crowned by a large obtuse stigma, which is permanent, divided into five parts, attended by a great number of stamina, crowned by oblong erect summits; the germen afterward becomes an oval seed-vessel, having five angles, and as many cells, which are filled with small rough seeds.

This genus of plants is ranged in Linnæus's thirteenth class, entitled Polyandria Monogynia, the flowers having many stamina and one germen.

We have but one SPECIES of this genus, viz.

ARGEMONE (*Mexicana*) capsulis quinque valvibus, foliis spinosis. Lin. Sp. 727. *Argemone whose capsule hath five valves, and the leaves are prickly; or Prickly Poppy.* Papaver spinosum. C. B. P. 171.

This is an annual plant, which is very common in most parts of the West-Indies, and is, by the Spaniards, called Fico del Inferno, or the Devil's Fig; there is no great beauty or use in this plant that I know of, but whoever hath a mind to cultivate it, should sow it on a bed of light earth, in the spring, where it is to remain; and if it comes up too thick, the plants must be thinned to four inches distance, where, when once it has shed its seed, there will not want a supply of plants for several years after. I have been informed that gumbouge is made from the juice of this plant, but how true I cannot take upon me to determine.

ARGIL [*Argilla*, Lat. a sort of white earth like chalk, but more brittle,] Pottery Clay.

ARIA THEOPHRASTI. See CRATÆGUS.

ARISARUM. See ARUM.

ARISTA, of corn, is that sharp-pointed needle that stands out from the husk or hove of the grain, called the beard or awn of corn.

ARISTOLOCHIA, [*Ἀριστολόχια* from *ἄριστος*, best, and *λοχία*, Child Birth, because supposed to be of so-reign use on that occasion.] Birthwort.

The CHARACTERS are,

The flower hath no empalement; it is of one leaf, which is unequal; the base is swelling and globular, afterward is extended into a cylindrical tube, which spreads at the brim, where the lower part is stretched out like a tongue. It hath no stamina, but there are six summits which join the under part of the stigma: the oblong angular germen sits under the flower, supporting a concave globular stigma, divided into six parts; the germen afterward turns to a large seed-vessel, differing in form, which opens in six cells, which are filled with seeds, for the most part compressed.

This genus of plants is ranged in the fifth section of Linnæus's twentieth class, entitled Gynandria Hexandria, the flowers being male and female in the same species, having no stamina or pointal, and six summits, which rest on the receptacle.

The SPECIES are,

1. **ARISTOLOCHIA** (*Rotunda*) foliis cordatis, subtusili-bus obtusis, caule infirmo, floribus solitariis. Lin. Sp. Plant. 962. *Birthwort with blunt heart-shaped leaves growing close, a weak stalk, and flowers growing singly.*

- singly. *Aristolochia rotunda* flore ex purpurâ nigro. C. B. P. 307.
2. *ARISTOLOCHIA (Longa)* foliis cordatis petiolatis integerrimis obtusiusculis, caule infirmo floribus solitariis. Lin. Sp. Plant. 962. *Birthwort with entire, heart-shaped, blunt leaves, having foot-stalks, a weak stalk, and flowers growing singly.* *Aristolochia longa* vera. C. B. P. 307.
 3. *ARISTOLOCHIA (Clematitis)* foliis cordatis caule erecto floribus axillaribus confertis. Hort. Upsal. 279. *Birthwort with heart-shaped leaves, an upright stalk, and flowers growing in clusters from the side.* *Aristolochia clematitis* recta. C. B. P. 307.
 4. *ARISTOLOCHIA (Pistolochia)* foliis cordatis, crenulatis petiolatis, floribus solitariis. Lin. Sp. Plant. 962. *Birthwort with heart-shaped indented leaves, having foot-stalks, and flowers growing singly.* *Aristolochia pistolochia* dicta. C. B. P. 307.
 5. *ARISTOLOCHIA (Sempervirens)* foliis cordato-oblongis undatis, caule infirmo, floribus solitariis. Lin. Sp. Plant. 961. *Birthwort with oblong, heart-shaped, waved leaves, a weak stalk, and flowers growing singly.* *Aristolochia pistolochia* dicta *Cretica* foliis smilacis sempervirens. H. L.
 6. *ARISTOLOCHIA (Serpentaria)* foliis cordato-oblongis planis, caulibus infirmis flexuosis, teretibus floribus solitariis. Lin. Sp. Plant. 961. *Birthwort with plain, oblong, heart-shaped, flexible, weak stalks, and flowers growing singly.* *Aristolochia pistolochia* five *Serpentaria Virginiana*. Pluk. Alm. 50. *Virginia Snakeroot.*
 7. *ARISTOLOCHIA (Arborescens)* foliis cordato-lanceolatis caule erecto fruticoso. Lin. Sp. Plant. 960. *Birthwort with spear-shaped leaves in form of a heart, and an upright shrubby stalk.* *Aristolochia polyrrhizos auriculatis* foliis *Virginiana*. Pluk. Alm. 50.
 8. *ARISTOLOCHIA (Indica)* foliis cordato-oblongis caule volubili pedunculis multifloris. Flor. Zeyl. 323. *Birthwort with oblong heart-shaped leaves, a twining stalk, and many flowers upon each foot-stalk.* *Aristolochia scandens* odoratissima floris labello purpureo semine cordato. Sloan. Cat. Jam. 60. *Contrayerva of Jamaica.*
 9. *ARISTOLOCHIA (Hirta)* foliis cordatis obtusiusculis hirtis floribus solitariis pendulis recurvatis subtruncatis. Lin. Sp. 1365. *Hairy Birthwort with obtuse heart-shaped leaves, and hanging recurved flowers growing singly, formed like a lip.* *Aristolochia longa* subhirsuta folio oblongo flore maximo. Tourn. Cor. 8.
 10. *ARISTOLOCHIA (Scandens)* foliis cordatis petiolis longissimis, caule scandente, floribus terminalibus pedunculis longissimis. *Birthwort with a climbing stalk, heart-shaped leaves with very long foot-stalks, and flowers growing at the end of the branches upon very long foot-stalks.*
 11. *ARISTOLOCHIA (Conferta)* foliis cordatis petiolatis, caule scandente, floribus axillaribus confertis. *Birthwort with heart-shaped leaves, a climbing stalk, and flowers growing in clusters from the wings of the stalk.*
 12. *ARISTOLOCHIA (Repens)* foliis lanceolatis sessilibus subhirsutis, caule erecto floribus solitariis longissimis. *Birthwort with spear-shaped hairy leaves growing close to the branches, an upright stalk, and very long flowers growing singly.* *Aristolochia erecta* flore atro purpureo foliis angustis radice repente. Houst. MSS.
 13. *ARISTOLOCHIA (Maxima)* foliis oblongo-ovatis obtusis integerrimis, caule scandente floribus terminalibus, fructibus hexangularibus maximis. *Birthwort with a climbing stalk, oblong, oval, entire, blunt leaves, flowers growing at the ends of the branches, and very large fruit with six angles.*

The first and second sorts grow naturally in the south of France, in Spain, and Italy, from whence their roots are brought for medicinal use. The roots of the first sort are roundish, and grow to the size of small Turneps, in shape and colour like the roots of the common Cyclamen; the roots of which are frequently sold in the markets for those of the round Birthwort, which at first may have been occasioned by the supposed virtues of the roots of the Cyclamen. This sends out three or four weak trailing branches,

which lie on the ground where they are not supported, and extend to the length of two feet; the leaves are heart-shaped, and rounded at their extremity; these are placed alternately on the stalks, and close to the foot-stalks of the leaves, the flowers come out singly, at every leaf, toward the upper part of the stalk. They are of a purplish black colour, and shaped like those of the other sorts, and are frequently succeeded by seed-vessels, having six cells, which are full of flat seeds. The flowers appear in June and July, and the seeds ripen in autumn.

The second sort hath long tap roots, shaped like those of Carrots; these send out weak trailing branches, which extend little more than a foot; the leaves of this sort are paler, and have longer foot-stalks than the first, placed alternately, and the flowers come out from the wings of the leaves like the other, which are not so long, and are of a pale purple colour: they are sometimes succeeded by oblong seed-vessels, having six cells filled with compressed seeds. The stalks of both these sorts decay in the autumn, and new ones are produced in the spring.

They are both propagated by seeds, which should be sown in the autumn, in pots filled with light earth, and placed under a frame, to be screened from the frost; but the glasses should be taken off at all times when the weather is mild. If these pots are put into a gentle hot-bed in March, it will bring up the plants much sooner than they otherwise would rise. As the season advances, the plants should be inured by degrees to bear the open air: when the pots are taken out of the bed, they must be placed where they may enjoy the morning sun, but screened from it in the heat of the day. Gentle refreshings of water must be in dry weather given to the plants during the summer, but in the autumn, when their stalks begin to decay, they must have little wet. In the winter the pots must be sheltered as before; and in March, before the roots begin to shoot, they should be transplanted into separate small pots filled with light earth, and set under the frame, where they should remain till spring; then they may be removed into the open air, and treated in the same manner as in the former summer, and sheltered also the following winter. The next spring they may be turned out of the pots, and planted in a warm border, where, during the summer, they will require no other care but to keep them clean from weeds; and in the autumn when their stalks are decayed, if the border is covered with old tanners bark to keep out the frost, the roots will be secured; but where this care is not taken, the roots are frequently killed by frost. With this management the roots will thrive much better than those which are kept in pots, and continue longer; and when they are three years old, they will flower and produce plenty of seeds, whereas those in pots seldom perfect their seeds in England.

When the seeds of these plants are sown in the spring, the plants will not appear till the spring following; so that a whole season is lost, and many times they fail, therefore it should always be sown in the autumn.

The third sort grows naturally in France, Spain, Italy, and Hungary, but is preserved in some of the English gardens, because it is sometimes used in medicine. This is a terrible plant for creeping at the root; so that if once it has taken in a garden, it will be difficult to extirpate again, and will over-run whatever plants grow near it; therefore it should be planted in some abject part of the garden by itself, for it will thrive in almost any soil or situation.

The fourth sort grows wild in Spain, Italy, and the south of France; but in England it is preserved, for variety, in botanic gardens. The plants of this sort must be planted in pots filled with light rich earth, and sheltered from severe cold in winter, otherwise they will not live; but they should have as much free air as possible in mild weather. This produces flowers every year, but never perfects its seeds in this country.

A R I

The fifth sort grows naturally in Crete. The root of this is perennial, and sends out many trailing branches, which extend one foot and a half in length, garnished with oblong heart-shaped leaves, which are waved on their edges, and are evergreen. The flowers come out singly from the wings of the leaves, which are of a dark purple colour, in shape like the others, but the plants never produce seeds in England, so is propagated by parting of the roots: this is too tender to thrive in the open air in winter; the plants are preserved in pots, and placed under a common frame in winter, where they should have as much free air as possible in mild weather, but screened from hard frost; in mild winters I have had this plant live abroad in a warm border, but in hard winters it will be destroyed; therefore one or two plants should be sheltered to preserve the species.

The sixth sort is the Snakeroot, which is greatly used in medicine: these roots are brought from Virginia and Carolina, where there are two species of this plant, but this sort is the best for use. There are some of these preserved in the gardens of those who are curious in collecting rare plants, but as they are sometimes killed by frost in winter, so they are not very common in the English gardens. This is propagated by seeds, which should be sown in the autumn, in small pots filled with light sandy earth, and placed under a common frame in winter, and afterward treated in the same manner as hath been directed for the two first sorts, as should the plants also; with which management they will produce their flowers, and perfect their seeds every year.

The seventh sort grows naturally in North America, and is by some called Snakeroot, but is not near so strong as the former; the branches of this grow erect, and are perennial, whereas those of the other sort decay to the root every winter: this rises about two feet high; the branches are not very woody, but are strong enough to support themselves; the leaves are oblong and heart-shaped; the flowers come out singly at the wings of the leaves. This will live abroad in warm borders, with a little protection in hard frosts. It is generally kept in pots, and sheltered in winter; but those which are planted in the full ground will thrive much better, provided they are screened from hard frosts.

The eighth sort grows naturally in Jamaica, where it is called Contrayerva; the roots are there used as such: this hath long trailing branches, which climb upon the neighbouring plants, and rise to a considerable height; the leaves are placed alternately, and are of the long heart-shaped kind; the flowers are produced in small clusters toward the upper part of the stalks, which are of a dark purple colour; the seed-vessels are oblong and smooth. This is tender, and in winter should have very little wet, therefore must be constantly kept in the stove, otherwise it will not live in England.

The ninth sort was discovered by Dr. Tournefort in the Levant. This hath some resemblance to the second sort, but the leaves are hairy, and not so deeply eared at the bottom; the flowers are also much larger. This may be propagated by seeds, in the same manner as hath been directed for the first and second sorts, and the plants treated so, will thrive very well in England.

The tenth sort sends out climbing stalks, which support themselves by fastening to the neighbouring trees, and thereby rise to a very great height; the leaves are very broad and heart-shaped, having several longitudinal veins; the flowers grow in loose bunches at the extremity of the branches, each having a long foot-stalk: this is tender, so must be kept in a stove, and treated as other exotic plants. It grows naturally about Tolu in New Spain, where it was discovered by the late Mr. Robert Millar, who sent the seeds to England.

The eleventh sort was discovered by the same gentleman at Campeachy in New Spain, from whence he sent the seeds: this sort seldom climbs above three

A R M

or four feet high; the leaves are short and heart-shaped, in some measure like those of the first; the flowers come out in small clusters from the wings of the leaves, and are of a dark purple colour.

The twelfth sort was discovered at La Vera Cruz in New Spain, by the late Dr. Houston, who sent the seeds to Europe: this rises with an upright stalk, to the height of three feet; the leaves are long, narrow, hairy, and grow close to the branches, having scarce any foot-stalk; the flowers come out singly from the wings of the leaves, which are near four inches long, of a dark purple colour, and grow erect; these are succeeded by slender vessels, about one inch long, which open into six cells, filled with flat heart-shaped seeds. This sort requires a warm stove to preserve it in this country.

The thirteenth sort was discovered by Mr. Robert Millar, near Carthage in New Spain, who sent it to England; this hath strong climbing stalks, by which it mounts up to the top of the tallest trees; the leaves of this are four inches long and two broad, of an oval shape, rounded at their ends, and are nearly as thick as those of the common Laurel; the flowers come out in loose clusters at the ends of the shoots, each standing on a very long foot-stalk; the seed-vessels are four inches long, and as much in circumference, having six longitudinal ribs, which make so many angles, being very prominent; they open into six cells, which are filled with heart-shaped leaves.

All these sorts, which are natives of the warm parts of America, are too tender to thrive in the open air in this country, therefore require a stove to preserve them. They are propagated by seeds, which must be procured from the countries where they grow naturally, for they do not produce any here. As the seeds are a considerable time in their passage, they should be brought over in their pods; for many of the sorts have very thin light seeds, which are soon dried in a hot country, when they are out of their covers, which will prevent their growing. So soon as the seeds arrive, they should be sown in small pots filled with light earth; and if this happens in the autumn, or winter, the pots should be plunged into the tan in the bark-stove, between some of the pots with large plants, which will screen them from the sun; for as these plants delight in shade, so, by thus placing of the pots, the earth will not dry very fast, which will be of great advantage to the seeds, which should not be too often watered. Here the pots may remain till March, at which time they should be removed, and plunged into a hot-bed, under frames, where, if the seeds are good, the plants will appear in May: but if the seeds arrive in spring or summer, they must be immediately sown in small pots, and plunged into a moderate hot-bed, observing to shade them constantly in the heat of the day; but the seeds sown at this season seldom grow the same year; therefore if the plants do not appear, the pots should be plunged in the tan-bed of the stove in autumn, and in the spring following, treated as before directed, which will bring up the plants. When these are strong enough to transplant, they should be each put into a separate small pot, and plunged into the tan-bed in the stove, and treated as other tender plants from the same countries.

ARMENIACA, the Apricot.

The CHARACTERS are,

The empalement of the flower is bell-shaped, cut into five blunt segments at the top; the flower is composed of five large roundish petals which spread open, whose base are inserted in the empalement; in the center is placed a round germen, supporting a slender style, crowned by a round stigma; this is attended by upward of twenty awl-shaped stamina, which are crowned by short double summits. The germen afterward becomes a roundish pulpy fruit, having a longitudinal furrow inclosing a roundish nut, which is a little compressed on the sides.

Dr. Linnaeus has joined the Armeniaca, Cerasus, Laurocerasus, and Padus, to his genus of Prunus, making them only so many species of the same genus, and

ranges it in his twelfth class of plants, entitled Icosandria Monogynia; the flowers of this class have from twenty to thirty stamina fastened to the empalement, and a single style.

The joining of so many plants under the same genus, as Linnæus has done, renders it much more difficult to ascertain their specific difference, than when they are ranged under different genera; and although most of them do agree in those parts from whence the characters according to his system are taken, yet if their fruits may be allowed as one of the characteristic notes (which surely ought not to be totally omitted) there will be reason for separating some of them, especially when we consider the boundary which nature has set between them; for it is well known that all fruits which are of the same genus, may be grafted or budded upon each other; but those of different genera will not take upon each other, nor will any two plants of different genera impregnate each other. Now the Cherry and Plum cannot by any art be made to take when grafted or budded upon stocks of the other kind; nor will the Apricot take upon the Cherry, the Laurel, or Padus; but it will grow upon the Plum to which it is nearly allied, therefore these may be joined together according to the strict rules of botany: yet in a work of this kind, designed for the instruction of the practical gardener, were these fruits to be included under the same appellation, it would rather confound than instruct, those who had not applied themselves to the study of botany: therefore I shall continue this genus under its former title, and shall enumerate all the varieties of this fruit which are at present cultivated in the English gardens, ranging them according to the orders of their ripening. For although most, if not all those which are by the gardeners called different sorts, may have been produced by culture, so should be deemed as one species; yet as the differences may be continued for ever, by the method in which they are propagated, so it would be unpardonable in a book of gardening to omit them.

The specific title given by Linnæus to the Apricot is, *Prunus floribus subsessilibus foliis subcordatis*. Sp. Plant. 474. i. e. *Plum whose flowers want foot-stalks, and heart-shaped leaves*.

The VARIETIES are,

1. The Masculine Apricot.
2. The Orange Apricot.
3. The Algier Apricot.
4. The Roman Apricot.
5. The Turkey Apricot.
6. The Breda Apricot.
7. The Brussels Apricot.

The Masculine is the first ripe of all the Apricots; it is a small roundish fruit, of a red colour towards the sun; as it ripens, the colour fades to a greenish yellow on the other side. It is chiefly preserved for being the first ripe, and there is a quickness in the flavour of the fruit when it is not too ripe, which renders it agreeable; the tree is very apt to be covered with flowers, but as they come out early in the spring, they are frequently destroyed by the cold, unless the trees are covered to protect them.

The Orange is the next ripe Apricot; this fruit is much larger than the former, and as it ripens changes to a deep yellow colour. The flesh of this is dry and not high flavoured, it is better for tarts than for the table.

The Algier is the next in season; this is of an oval shape, a little compressed on the sides; it turns to a pale yellow, or straw-colour, when ripe; the flesh is high flavoured, and very full of juice.

The Roman is the next ripe Apricot; this is a larger fruit than the former, and not compressed so much on the sides; the colour is deeper, and the flesh is not so moist as the former.

The Turkey Apricot is yet larger than either of the former, and of a globular figure; the fruit turns to a deeper colour than the former; the flesh is firmer, and drier than those of the two former.

The Breda Apricot (as it is called from its being brought from thence into England) was originally brought from Africa: this is a large roundish fruit, changing to a deep yellow when ripe; the flesh is soft, full of juice, and of a deep Orange colour within side; the stone is rounder and larger than any of the other sorts: this is the best Apricot we have, and when ripened on a standard, is preferable to all other kinds.

The Brussels is the latest ripe of all the Apricots, for when it is planted against a wall, it is generally the beginning of August before it is ripe, unless when it is planted to a full south aspect; which is what should not be practised, because the fruit is never well tasted which grows in a warm exposure. This fruit is of a middling size, rather inclining to an oval figure; red on the side next the sun, with many dark spots, and of a greenish yellow on the other side; the flesh is firm, and of a high flavour; the fruit often cracks before it is ripe. This is commonly preferred to the former sort by most people, but when the other is planted as a standard, the fruit is fuller of juice, and of a richer flavour than this.

Most people train these trees up to stems of six or seven feet high, or bud them upon stocks of that height; but this is a practice I would not recommend to the public, because the higher the heads of these trees are, the more they are exposed to the cutting winds in the spring, which too frequently destroy the blossoms; and the fruit is also more liable to be blown down in summer, especially if there should happen to be much wind at the time when the fruit is ripe; which by falling from a great height, will be bruised and spoiled; therefore I prefer half standards, of about two and a half, or three feet in the stem, to those which are much taller; or to plant them as dwarfs against an espalier, where, if they are skilfully managed, they will produce a large quantity of good fruit; and the trees in espalier may be more conveniently covered in the spring, when the season proves bad, whereby there will be a greater certainty of fruit every year.

These fruits are all propagated by budding them on Plum-stocks, and will readily take upon almost any sort of Plum, provided the stock be free and thriving (except the Brussels kind, which is usually budded on a sort of stock, commonly called the St. Julian, which better suits this tree, as being generally planted for standards, than any other sort of Plum will.) The manner of raising the stocks, and budding these trees, shall be treated of under their particular articles, to which I refer the reader, and shall proceed to their planting and management.

These trees are all (except the two last sorts) planted against walls, and should have an east or west aspect; for if they are planted full south, the great heat causes them to be mealy before they are eatable.

The borders near these walls should be six or eight feet wide, at least, and if it were more, the better; but I would never advise the making of them so deep as is the general custom, for if the earth be two feet deep, or two and a half at most, it is enough.

If the ground is a wet cold loam or clay, the borders should be raised as much above the level of the surface as it will admit, laying some stones or rubbish in the bottom, to prevent the roots from running downwards; but if you plant upon a chalk or gravel, it will be better to raise the borders above either to a proper thickness, with good loamy earth, than to sink the borders by removing the chalk or gravel; for although these are removed the whole breadth of the border, which we may allow to be eight feet, and this trench filled with good earth, yet the roots of the trees will in a few years extend this length, and then meeting with the chalk or gravel, they will receive a check whereby their leaves will fall off early in the season, and the fruit will be small, dry, and ill-flavoured, and the shoots of the trees will be weak. But where the borders are raised upon either to their full height, the roots will not strike down into

into

A R M

into the gravel or chalk, but rather extend themselves near the surface, where they will meet with better soil: and as the trees are of long duration, and old trees being not only more fruitful than young, but the fruit is also better flavoured, therefore the providing for their continuance is absolutely necessary.

The soil I would in general advise to be used for these, and all other sorts of fruit-trees, is fresh untried earth, from a pasture ground, taken about ten inches deep, with the turf, and laid to rot and mellow at least twelve months before it is used, mixing a little rotten dung with it; this must be often turned, to sweeten and imbibe the nitrous particles of the air.

When the former soil of the border is taken away, this fresh earth should be carried in the place; and if the borders are filled with it two months before the trees are planted, the ground will be better settled, and not so liable to sink after the trees are planted: in filling of the borders, the ground should be raised four or five inches above the level they are designed, to allow for the settling.

The borders being thus prepared, make choice of such trees as are but of one year's growth from budding; and if the soil is dry, or of a middling temper, October is the best season for planting, especially having at that time a greater choice of trees from the nurseries, before they have been picked and drawn over by other people. The manner of preparing these trees for planting being the same in common with other fruit trees, I shall refer the reader to the article of PEACHES, where he will find it largely treated of. At the time of planting no part of the head of the trees should be cut off, unless there are any strong foreright shoots which will not come to the wall, which may be taken quite away.

The trees being thus prepared, you must mark out the distances they are to stand, which in a good strong soil, or against a low wall, should be twenty feet or more; but in a moderate one, eighteen feet is a good reasonable distance; then make a hole where each tree is to stand, and place its stem about four inches from the wall, inclining the head thereto; and after having fixed the tree in the ground, nail the branches to the wall, to prevent their shaking, and cover the surface of the ground round the root with rotten dung, to keep out the frost: in this state let it remain till the end of February or the beginning of March, when if the weather is good, you must unnailed the branches of your trees, so as not to disturb their roots; and, being provided with a sharp knife, put your foot close to the stem of the tree; and having placed your left-hand to the bottom of the tree, to prevent its being disturbed, with your right-hand cut off the head of the tree, if it has but one stem; or where it may have two or more shoots, each of them must be shortened, to about four or five eyes above the bud, so that the sloping side may be toward the wall.

In the spring, if the weather proves dry, it will be necessary to give the trees a gentle refreshing with water; in the doing of which, if they watered with a rose to the watering-pot all over their heads, it will greatly help them; and also lay some turf, in the manner directed for Apples, or some other mulch, round their roots, to prevent their drying during the summer season; and in the spring, as new branches are produced, observe to nail them to the wall in a horizontal position; and such shoots as are produced fore-right, must be entirely displaced. This must be repeated as often as is necessary, to prevent their hanging from the wall, but by no means stop any of the shoots in summer.

At Michaelmas, when the trees have done growing, their branches should be unnailed, and shorten them in proportion to their strength; a vigorous branch may be left eight or nine inches long, but a weak one should not be left above five or six. I suppose many persons will wonder at this direction, especially having allowed such a distance between the trees, as believing, by this management, the wall will never be filled; but my reason for it is, that I would have no part of

A R N

the wall left unfurnished with bearing wood; which must consequently be the case, if the branches are left to a greater length at first; for it seldom happens, that more buds than two or three upon each branch shoot; and these are, for the most part, such as are at or near the extreme part of the last year's wood; so that all the lower part of the shoots become naked, nor will they ever after produce shoots; and this is the reason, we see so many trees which have their bearing wood situated only in the extreme part of the tree.

When you have shortened the shoots, be sure to nail them as horizontally as possible, for upon this it is that the future good of the tree chiefly depends.

The second summer observe, as in the first, to displace all fore-right shoots as they are produced, nailing in the other close to the wall horizontally, so that the middle of the tree may be kept open; and never shorten any of the shoots in summer, unless to furnish branches to fill vacant places on the wall; and never do this later than the end of April, for reasons hereafter given in the article of Peaches. At Michaelmas shorten these shoots, as was directed for the first year; the strong ones may be left nine or ten inches, and the weak ones six or seven at most.

The following year's management will be nearly the same with this, but only observe, that Apricots produce their blossom buds, not only upon the last year's wood, but also upon the cufsons, or spurs, which are produced from the two years wood; a great care should therefore be had in the summer management, not to hurt or displace these: observe also to shorten the branches at the winter pruning, so as to furnish fresh wood in every part of the tree; and be sure to cut out entirely all luxuriant branches, or displace them as soon as they are produced; which, if left to grow, would exhaust the nourishment from the bearing branches, which in my opinion, cannot be too strong, provided they are kindly; for the more vigorous the tree is, the more likely it is to resist the injuries of the weather; though we often see trees brought to so weak a condition, as to be able only faintly to blow their blossoms, and then most of the bearing branches have died; which has given occasion to the owner to imagine it was the effect of a blight, when, in reality, it was only for want of right management. And, I am fully persuaded, half the blights we hear complained of, proceed from nothing else but this.

These few rules, well executed, together with a little observation and care, will be sufficient, therefore to pretend to prescribe particular directions for all the different accidents, or manner of treating fruits, would be impossible; but I believe the reader will find what has been said, if duly attended to, will answer his design; for, without diligent observation, there can be no such thing as a skilful manager, let him have ever so many or good instructions laid down to him.

The Brussels and Breda Apricots, being, for the most part, planted for standards, will require very little pruning or management; only observe to take out all dead wood, or such branches as cross each other; this must be done early in autumn, or in the spring, after the cold weather is past, that the part may not canker where the incision is made.

ARMERIUS, Sweet-William. See DIANTHUS.

ARNICA. Lin. Gen. Plant. 784. Doronicum. Bauh. Pin. 184. Leopardbane.

The CHARACTERS are,

The common empalement is scaly, and shorter than the rays of the flower. It hath a compound flower, the border or rays being composed of many female florets, which spread open, cut into three parts at their end; the disk, or middle, has many hermaphrodite florets, which are tubulous, cut into three unequal segments at the brim; these have each five short stamina, crowned with oblong summits. The female florets have also five awl-shaped stamina, but no summits; in the hermaphrodite florets the germen is situated below the flower, supporting a slender short style, crowned by a bifid stigma. The germen afterward becomes a single oblong seed, crowned with long slender down.

This

A R T

This genus of plants is ranged in the second section of Linnæus's eighteenth class, entitled Syngenesia Polygamia superflua, the flower being composed of hermaphrodite and female florets; and the chief distinction of this genus is in the hermaphrodite and female flowers being of the same shape, and the female having stamina.

The SPECIES are,

1. ARNICA (*Montana*) foliis ovatis integris, caulinis geminis oppositis. Lin. Sp. Plant. 884. *Arnica with entire oval leaves, those on the stalks growing opposite by pairs.* Doronicum plantaginis folio alterum. C. B. P. 185.

2. ARNICA (*Scorpioides*) foliis alternis serratis. Hall. Helvet. 737. *Arnica with sawed leaves growing alternately.* Doronicum radice dulci. C. B. P. 184.

3. ARNICA (*Crocea*) foliis ovalibus serrato denticulatis, subtus tomentosis. Lin. Sp. Plant. 1246. *Arnica with oval indented leaves, whose undersides are woolly.* Dens leonis enule folio. Pet. Mus. 393.

The first sort grows naturally upon the Alps, and also upon many of the mountains in Germany, and other cold parts of Europe, and is greatly esteemed by the Germans for its medicinal qualities, where it is prescribed by this title of Arnica. It is also ranged among the medicinal plants in many dispensaries, by the title given to it by Caspar Bauhin.

The roots of this plant, when placed in a proper soil and situation, greatly increase, for they send out thick fleshy roots, which spread very far under the surface; these put out many oval entire leaves, from between which the flower-stems arise, which grow about a foot and a half high, having two or three pair of leaves growing opposite upon each, and the top is terminated by a single yellow flower, composed of many florets, like those of Dandelion. These are succeeded by oblong seeds, which are crowned with down, whereby they are dispersed to a considerable distance when ripe. It flowers in April and May, and the seeds ripen in September.

This plant delights in a moist shady situation; it may be propagated by parting of the root in autumn, when the stalks begin to decay, or by the seeds if sown in autumn, soon after they are ripe, for those sown in the spring often fail; but if the seeds are permitted to scatter, the plants will come up the following spring, so that when one plant is obtained, it will propagate itself fast enough without other care, but to keep it clean from weeds.

The second sort grows naturally on the mountains of Bohemia, as also in Siberia, from whence I received the seeds. The roots of this sort are much jointed, and divide into many irregular fleshy offsets, which are variously contorted; from whence many superstitious persons have been led to imagine, that the roots would expel the poison of scorpions, and cure the wounds made by the bite of that animal. It is a very hardy plant, and is propagated in the same manner as the former.

The third sort grows naturally at the Cape of Good Hope, from whence the seeds have been brought to Europe. This will not live through the winter in the open air in this country, so the plants must be kept in pots, which should be placed under a common hot-bed frame in winter, to screen it from the frost, but should enjoy the free air at all times, when the weather is mild. It propagates by roots and seeds in plenty. This is titled by Dr. Burman, *Gerbera foliis planis dentatis flore purpureo.* Plant. Afr. 157.

ARTEDIA. Lin. Gen. Plant. 249. We have no English name for this genus.

The CHARACTERS are,

It is an umbelliferous plant; the greater umbel is spread open, and composed of many small ones; the involucre of the large one is composed of ten oblong leaves, which extend the length of the umbel, cut at their tips into three parts. The involucre of the small umbels have but three narrow leaves, which are longer than the umbel; the rays of the large umbel are disform, those of the small ones in the disk are male, and the rays are hermaphrodite. They

A R T

have five petals, which are erect, heart-shaped, and turned inward. These have each five slender stamina, crowned with roundish summits; those flowers which compose the rays, have a small germen at bottom, supporting two reflexed styles, crowned by a single stigma. The germen afterward becomes a roundish compressed fruit, with a leafy border, which splits into two, and contains two oblong seeds, with scaly borders.

This genus of plants is ranged in the second section of Linnæus's fifth class, entitled Pentandria Digynia, from their flowers having five stamina and two styles.

We have but one SPECIES of this plant, viz.

1. ARTEDIA (*Squamata*) seminibus squamatis. Hort. Cliff. 89. *Artedia with squamous seeds.* Thapsia Orientalis anethi folio semine eleganter crenato. Tourn. Cor. 22.

This is a native of the east. Rawvolf found it growing upon Mount Libanus; it is an annual plant, whose stalks rise about two feet high, sending out a few side branches, garnished with narrow compound leaves resembling those of Dill; the extremity of the stalk is terminated by a large umbel of white flowers, composed of five unequal petals, those on the outside being much larger than the other. These are succeeded by roundish compressed fruit, each having two seeds, whose borders are scaly.

This plant decays as soon as the seeds are perfected, and many times before they are ripe in England; for unless the seeds are sown in autumn, and the plants come up before winter, they rarely produce good seeds here. The seeds should be sown on a warm border where the plants are to remain, for they will not bear transplanting. All the care they require is to keep them clean from weeds, and thin the plants to six or eight inches distance. They flower in June, and their seeds ripen the end of August.

ARTEMISIA [*Ἀρtemisia*, Gr. so called, according to some, from Artemisia, wife of Mausolus, king of Caria, who brought this plant into use, and adopted it as hers; whereas, before, it was called Parthenis, the virgin goddess being feigned to have given that name to it.] Mugwort.

The CHARACTERS are,

The common empalement is scaly and round, as are also the scales. The flower is composed of hermaphrodite and female florets, the border being ranged with the female, which have a small germen at bottom, supporting a slender style, crowned by a bifid stigma. The hermaphrodite florets compose the disk, or middle; these are tubulous, cut into five parts at the brim; in the center is placed the germen, with the like style and stigma as the female, accompanied by five hairy stamina, crowned by cylindrical summits, which are indented in five parts. The germen afterward becomes a single naked seed, sitting upon a naked placenta.

This genus of plants is ranged in the second section of Linnæus's eighteenth class, entitled Syngenesia Polygamia superflua, the flowers of these being composed of female and hermaphrodite florets, which are both fruitful.

The SPECIES are,

1. ARTEMISIA (*Vulgaris*) foliis pinnatifidis planis incis; subtus tomentosis, racemis simplicibus floribus ovatis radio quinque floro. Lin. Sp. Plant. 348. *Mugwort with plain cut leaves, ending in many parts, woolly underneath, with single spikes of oval flowers, whose rays are composed of five florets.* Artemisia vulgaris major. C. B. P. 137.

2. ARTEMISIA (*Integrifolia*) foliis lanceolatis subtus tomentosis integerrimis dentatisque florum radio subquinque floro. Lin. Sp. Plant. 1189. *Mugwort with spear-shaped entire leaves, indented on their edges, whose undersides are woolly, and the rays of the flower composed of five florets.* Artemisia foliis planis lanceolato-linearibus inferioribus sæpe ex pinnato-dentatis. Flor. Sib. 2. p. 109.

3. ARTEMISIA (*Cærulescens*) foliis caulinis lanceolatis integris; radicalibus multifidis, flosculis fœmineis ternis. Lin. Sp. 1189. *Mugwort whose leaves on the stalks are entire,*

A R T

- entire, those at the root multifid, and three female floscules compose the rays of the flower. *Ab-sinthium maritimum* lavendulæ folio. C. B. P. 139. *Lavender-leaved Sea Wormwood*.
4. ARTEMISIA (*Dracunculus*) foliis lanceolatis glabris integerrimis. Hort. Cliff. 403. *Mugwort with spear-shaped, entire, smooth leaves*. *Abrotanum lini* folio acrore & odorato. Tourn. Inst. 459. *Tarragon*.

The first sort grows naturally on banks, and by the side of foot-paths, in most parts of England, so is rarely admitted into gardens, where it would soon become a troublesome weed; for the roots creep far under the surface of the ground, so that unless they are stopped, they will soon spread over a large space of ground; but as this plant is used in medicine, I have here mentioned it. This flowers in June, at which time the herb is in perfection for use.

The Moxa, so famous in the eastern countries for curing the gout by burning of the part affected, is the lanugo, or down, which is on the under par. of the leaves, of a sort of Mugwort, which is supposed to be different from our common sort, but the dried samples which I have seen brought to England for that, appear to differ in nothing but the size of the plant, that being much less; and I suppose the soft down of the common sort, or of any other plant, will answer the purpose full as well.

The second sort grows naturally in Siberia; this rises up with single stalks about two feet high, which are garnished with plain, narrow, spear-shaped leaves, cut into acute segments on their edges, somewhat like those of Buckthorn Plantain; the flowers come out from the wings of the leaves in small loose spikes, and near the top they are often single; these are larger than those of the common sort, and are of a pale yellow colour.

This sort is as hardy as the common, and multiplies as fast, so is only preserved in botanic gardens for the sake of variety.

The third sort grows naturally near the sea, in Italy, Spain, and France, but is hardy enough to live in the open air in England, provided it is planted in a dry soil: it grows too feet high, having many ligneous branches, which are terminated by spikes of flowers, which have little beauty, therefore the plants are preserved in gardens for the sake of variety.

The fourth sort is the common Tarragon, which is frequently used in sallads, especially by the French: this is a very hardy plant, which propagates greatly by its creeping roots, or may be multiplied fast by planting the young shoots the beginning of May, in the same manner as is practised for Mint, and if they are duly supplied with water in dry weather, will soon spread and meet.

The fifth sort grows naturally in China, but is hardy enough to thrive in the open air here. It is an annual plant, which seldom comes up the first year, if the seeds are sown in the spring; therefore it is much better to let the seeds scatter in the autumn, because these will more surely grow, than those sown by hand.

The sixth sort is the common Southernwood, which is kept in gardens for the agreeable scent of its leaves; it is a low under shrub, seldom rising more than three or four feet high, sending out lateral shrubby branches growing erect, garnished with five bristly leaves, having an agreeable scent when bruised: the flowers are produced in spikes from the extremity of the branches, but unless the autumn proves warm and dry, the flowers rarely open in England.

This is propagated by slips and cuttings, planted in a shady border, about the beginning of April, observing to water them duly in dry weather; in this border they may remain till the following autumn, when they should be transplanted, either into pots or those parts of the garden where they are designed to remain.

The seventh sort is a very low under shrub, the branches bend near the ground, so never rise more than

than two feet high, unless when they flower; for the spikes are generally more than a foot long; the flowers are yellow, and are ranged in spikes which appear in autumn. This is propagated either by slips or cuttings in the same manner as the former, and is equally hardy.

The eighth sort produces the Semen Santonicum, which is much used for worms in children. It grows naturally in Persia, from whence the seeds are brought to Europe; this hath the appearance of our Wild Mugwort; the branches are slender, erect, and garnished with linear winged leaves, and terminated by recurved slender spikes of flowers, which have naked receptacles. This may be propagated by slips or cuttings in the like manner as the former; but the plants should be planted in a dry soil and sheltered situation, where they will endure the cold of our ordinary winters pretty well; but it will be proper to have a plant or two in pots, which may be sheltered in winter under a common hot-bed frame to preserve the species.

The ninth sort is our common Wild Southernwood, which grows naturally in some parts of Norfolk, so is rarely admitted into gardens.

The tenth sort grows naturally in Portugal; this is a low under shrub, seldom rising more than two feet high, and has much of the aspect of our wild sort, so is rarely kept in gardens in this country.

The eleventh sort is the common Sea Wormwood, grows naturally on the sea coasts in most parts of England, where there are several varieties (if not distinct species) to be found. These are low under shrubs, most of them creep at their root, whereby they multiply greatly in their natural situation, but when transplanted into a garden, seldom thrive so well; however, these varieties are now commonly substituted for the true Roman Wormwood in the London shops.

The twelfth sort grows naturally on the Alps; this is also a low under shrub, seldom rising more than a foot high, sending out several slender branches, garnished with very white winged leaves, for which the plants are sometimes admitted into gardens. It is very hardy, and may be easily propagated by cuttings in the spring.

The thirteenth sort is the true Roman Wormwood, though at this time never used in any of the shops; yet by skilful persons is greatly preferred to the Sea Wormwood, being less nauseous and a much pleasanter bitter, and may be had in as great plenty, provided it was cultivated by those who supply the markets with medicinal herbs. This is a low herbaceous plant, whose stalks die to the root in autumn, and new ones arise in the spring; these are garnished with finely divided leaves, whose underside are woolly; the upper part of the stalks are furnished with globular flowers which nod on one side, having naked receptacles. These appear in August, but are rarely succeeded by seeds in England.

This sort is easily propagated by its creeping roots, which may be parted in the autumn, and planted two or three feet asunder, that they may have room to spread; the best time for this is in the middle of October; it will grow in any soil which is not too wet.

The fourteenth sort grows naturally in Siberia; it is an annual plant which grows two feet high, garnished with smooth winged leaves, which have an agreeable scent; the flowers are globular and nod on one side. If the seeds of this are permitted to scatter in the autumn, the plants will come up better than if sown with care.

The fifteenth sort is the common Wormwood which grows naturally in lanes and uncultivated places in many parts of England, so is not often cultivated in gardens. This is easily propagated by seeds, which should be sown in the autumn soon after they are ripe; or if they are permitted to scatter, the plants will come up without farther care.

The sixteenth sort has been supposed to be a variety

of the common Wormwood: indeed the appearance of the plants are nearly alike, but the segments of the leaves of this are broader and whiter than those of the common; and the whole plant is insipid, and continues so from seed.

The seventeenth sort is commonly known by the title of Tree Wormwood; this grows naturally near the sea in Italy and the Levant. This rises with a woody stalk six or seven feet high, sending out many ligneous branches, garnished with leaves somewhat like those of the common Wormwood, but more finely divided, and much whiter. The branches are terminated by spikes of globular flowers in the autumn, which are seldom succeeded by seeds here. This plant is easily propagated by cuttings, which, if planted in a shady border during the summer season, and duly watered, take root freely. In autumn some of the young plants should be potted, that they may be sheltered in winter; the other may be planted in a warm border, where they will live; provided the winter proves favourable.

The eighteenth sort is a low shrubby plant; the stalk is woolly, sending out a few shrubby branches, garnished with linear leaves growing in clusters; the flowers grow in a roundish bunch, and are shaped like those of Wormwood. This grows naturally in Ethiopia. It is propagated by planting the cuttings any time in summer, and the plants must be sheltered from hard frosts in winter.

The nineteenth sort grows naturally on the Alps; this is a low plant, seldom rising more than a foot and a half high; the stalks are closely garnished with very white leaves shaped like a hand; the flowers are globular, and produced in clusters at the extremity of the stalk; these are rarely succeeded by seeds in England. This plant may be propagated by planting the side shoots in a shady border during any of the summer months, which, if duly watered, will put out roots, and in autumn they may be transplanted where they are to remain.

The twentieth sort grows naturally at Piedmont; it is an herbaceous plant, whose stalks die to the root in winter, and fresh shoots arise in the spring, which are garnished with winged leaves, woolly on their under side; the flowers are produced on single spikes, which are rarely succeeded by seeds in England. It may be easily propagated by parting the roots in the autumn.

ARTICHOKE is called by the Latins *Cinara*.

As this plant is much better known by its English title than the Latin, I shall treat of it under this head, and refer for its character to the Latin title of *Cinara*, under which the other species will be exhibited.

We have two sorts of Artichokes which are cultivated in the English gardens, which we shall distinguish here only by the names they are generally known among the gardeners, and reserve their farther distinctions to their Latin titles.

The best sort is what the gardeners call the Globe Artichoke. This hath large heads with broad brown scales, which turn inward; the fleshy part at the bottom of the scales is very thick, therefore is much preferred to the other, which is called the French Artichoke. The stalks of this sort generally grow taller, and the heads are smaller, and more conical than those of the other sort. The scales are narrower, of a greener colour, and turn outward. The fleshy part which is eaten is not near so thick, and hath a disagreeable perfumed taste; this was almost totally rooted out of the English gardens before the hard frost in 1733, when the greatest part of the roots of the other sort were destroyed, so many persons were supplied the following spring with plants from Guernsey, where they cultivate only the latter sort; but since the other has been increased again, this green sort has been in most gardens rooted out, to make way for the Globe Artichoke.

The manner of propagating this plant is from slips, taken from the old roots, in February or March, which, if planted in a good soil, will produce large fair

A R T

fair fruit the autumn following; but as this is a plant which few gardeners, that have not been instructed in the kitchen-gardens near London, understand to manage well, I shall be the more particular in my directions about it.

At the latter end of February, or in March, according to the earliness of the season, or forwardness of the old Artichoke roots, will be the proper time for dressing them, which must be thus performed: with your spade remove all the earth from about your stock, down below the part from whence the young shoots are produced, clearing the earth from between the shoots with the hands, so as to be able to judge of the goodness of each, with their proper position upon the stock; then make choice of two of the clearest, straightest, and most promising plants that are produced from the under part of the stock, which are much preferable to the strong thick plants which generally grow upon the crown of the roots; for these have hard woody stems, so never produce good fruit, but are generally what the market people call rogues, which have very little bottom; the scales of their heads are irregularly placed; in slipping off the plants you must be careful not to injure those which are to remain for a crop; then with your thumb force off all the other plants and buds also close to the head of the stock, from whence they are produced, being very careful not to leave any of the buds, which will soon produce plants so as to hurt those which are left: then with your spade draw the earth about the two plants which are left, and with your hands close it fast to each of them, separating them as far asunder as they can conveniently be placed without breaking them, observing to crop off the tops of the leaves which hang down with your hands; your ground being levelled between the stocks, you may sow thereon a small crop of Spinach, which will be taken off before the Artichokes will cover the ground, and be sure to keep them clear from weeds; and toward the latter end of April, or the beginning of May, when your old plants begin to shew their fruit, you must carefully look over your stocks, and draw up all young plants from them, which may have been produced since their dressing, and cut off all suckers which are produced from the stems of the Artichoke, leaving only the principal head, by which means your fruit will be the larger; when your Artichokes are fit to gather, you must break or cut them down close to the surface of the ground, that your stocks may make strong fresh shoots before the end of October: the season for earthing, or, as the gardeners term it, landing them up, is the middle or latter end of November, which is thus done:

Cut off all the young shoots quite close to the surface of the ground; then dig between every stock, raising all the earth between each row of stocks into a ridge, as is done in the common method of trenching ground, so as that the row of Artichokes may be exactly in the middle of each ridge, this will be sufficient to guard them against frost; and I would here recommend it to the public, as infinitely preferable to long dung, which is by the unskilful often used, and is the occasion of their fruit being small, and almost without any bottoms to them; for there is not any thing so hurtful to these, as new dung being either buried near, or laid about them.

Since we have experienced, that, in very severe frosts these roots are sometimes destroyed, therefore it is proper to give some directions to prevent it; though this rarely happens in dry ground, in which we have but few instances of their being killed, except in the hard frosts of 1683, and 1742. In these two winters most of the Artichokes were destroyed in England; in the last of these winters, it happened from the little care which was taken of them, there having been no frost for so many years before, which had injured them, that few people used any care to preserve them; but since that hard frost, many people have run into the other extreme of covering all their roots of Artichokes with long dung every winter, which is a very

A R T

bad method, because the dung lying near the roots, is very apt to rot the best plants; therefore I would advise the earthing (or as it is called by the gardeners, landing) the Artichokes to be deferred till the latter end of November, or the beginning of December, provided the season continues mild; and towards Christmas, if there is any danger of severe frosts, to lay a quantity of long dung, Pease-haulm, tanners bark, or any other light covering over the ridges of earth, which will keep out the frost; and this being at a distance from the roots, will not injure them; but this covering should be carefully taken off the beginning of February, or sooner, provided the season is mild, or at least so soon as the weather is so, otherwise the plants will be injured by its lying too long upon them.

It will also be a good method, whenever any roots of Artichokes are dug up in autumn, either to bury them deep in the ground in a pit till spring, or lay them in a heap, so as that they may be easily covered in hard frosts; and these may be a supply, if those in the ground are destroyed.

When you have thus earthed them up, you have nothing more to do till February or March, by which time they will have grown through the ridge of the earth; and, when the weather is proper, must be dressed as was before directed.

When you have a mind to make a new plantation, after having digged and buried some very rotten dung in the ground you have allotted for that purpose, make choice of such of your plants as were taken from your old stocks, which are clear, sound, and not woody, having some fibres to their bottom; then with your knife cut off that knobbed woody part, which joined them to the stock; and if that cuts crisp and tender, it is a sign of its goodness, but if tough and stringy, throw it away as good for nothing; then cut off the large outside leaves pretty low, that the middle or heart leaves, may be above them. Your plants being thus prepared (if the weather is very dry, or the plants have been any time taken from the stocks, it will be convenient to set them upright in a tub of water for three or four hours before they are planted, which will greatly refresh them;) you must then proceed to planting, which must be done by ranging a line across the ground, in order to their being placed exactly in a row; and, with a measure stick, plant them at two feet distance from each other in the rows, and if designed for a full crop, five feet distance row from row; your plants must be set about four inches deep, and the earth closed very fast to their roots, observing, if the season proves dry, to keep them watered two or three times a week, until they are growing, after which they seldom require any.

N. B. You may sow a thin crop of Spinach upon the ground before you plant your plants, observing to clear it from about them after it is come up.

These plants, in a kindly season, or a moist soil, will produce the largest and best Artichokes some time in August and September, after all those from the old stocks are past; so that if you intend to continue your Artichokes through the whole season, you must make a new plantation every year, otherwise you cannot possibly have fruit longer than two or three months.

If any of the plants which are planted in the spring should not fruit in autumn, you may, at the season of earthing up your roots, tie up the leaves with a small Willow twig, &c. and lay the earth up close to it, so that the top of the plant may be above ground; and when the frost comes on, if you will cover the top with a little straw, or Pease-haulm, to prevent their being killed by frost, these plants will produce fruit in winter, or early in the spring.

But in those plantations where you intend to plant other things between your Artichokes, you must allow nine or ten feet between the rows, as is often practised by the kitchen-gardeners near London, who sow the ground between with Radishes or Spinach, and

and plant two rows of Cauliflowers, at four feet distance row from row, and two feet and a half asunder in the rows, so that there are always five feet allowed for the Artichokes to grow; and in May, when the Radishes or Spinach are taken off, they sow a row of Cucumbers for pickling, exactly between the two rows of Cauliflowers, at three feet distance from each other; and between the rows of Cauliflowers and the Artichokes, plant a row of Cabbages or Savoy for winter use, which, when the Cauliflowers are drawn off, and the Artichokes gathered, will have full liberty to grow, and by this means the ground is fully employed through the whole season. This has long been the practice of the kitchen-gardeners near London, who pay large rents for their land, so are obliged to get as many crops in a year from it as possible.

In those which are planted at five feet distance row from row, you may plant in every other row a line of Cabbages or Savoy for winter use, which will be gone by the time of landing them up; in doing of which you must lay the whole five feet of earth into one ridge, except the ground be extreme stiff, or the plants young, in both which cases you may lay only three feet and a half of the ground in the ridge over the roots, and the remainder may be laid in a small ridge between; the same compass of ground must also be allowed where they are planted at a wider distance.

And if in the spring you find your stocks shoot very weak, which may have been occasioned either by hard frost, or too much wet, you must then uncover them, and with your spade loosen and break the earth about them, raising a small hill about each stock, levelling the rest between the rows, which will greatly help them, and in three weeks, or a month's time after, they are commonly fit to slip.

Those Artichokes which are planted in a moist rich soil, will always produce the largest and best fruit; so that where such a soil can be obtained, it will be proper to make a fresh plantation every spring, to succeed the old stocks, and supply the table in autumn. But the roots will not live through the winter in a moist soil, so that your stocks which you intend should remain to supply the table early, and to furnish plants, should be in a drier soil. You should always observe to plant these in an open situation, and not under the drip of trees, where they will draw up very tall, and produce small insignificant fruit.

ARTICHOKES of Jerusalem. See **HELIANTHUS**.

ARTICULATION, is the connection of parts that consist of joints, or knees, such as are the siliques [the husks] of many plants; as of the Ornithopodium, Coronilla, which are joined together by a soluble knot; whence those parts are called articulosæ, and are said to be connected articulatum, or geniculatum; and such plants are called Articulosæ, whose roots are jointed, although the stalks have no joints; so the root of Polygonatum is said to be articulosæ, or geniculated.

ARUM, Wake Robin, or Cuckow Pint.

The **CHARACTERS** are,

The flower hath a large oblong spathe, which is closed at the bottom, compressed in the middle, and coloured within; the spadix is single, shaped like a club at the top, and shorter than the spathe upon which the germen are situated. It hath no petals nor stamina, but many four-cornered summits, sitting close to the germen, with a double row of hairs between them, which adhere to the spadix. There are many oval germen which surround the upper part of the spadix, having no styles, but have bearded stigma: the germen afterward become globular berries, with one cell, having round seeds.

This genus of plants is ranged in the seventh section of Linnæus's twentieth class, entitled Gynandria Polyandria, these plants having male and female flowers joined, but have no stamina nor style, but many summits.

This plant is called Wake Robin, from the sharp acrid taste, which, if eaten, will occasion a violent pain in every part of the mouth and throat, attended commonly with a great defluxion of water.

The **SPECIES** are,

1. **ARUM** (*Maculatum*) acaule foliis hastatis integerrimis spadice clavato. Hort. Upsal. 434. *Arum without stalk, spear-shaped entire leaves, and a club-shaped spadix.* Arum vulgare maculatum & non maculatum. C. B. P. 195. *The common Arum.*
2. **ARUM** (*Italicum*) foliis hastatis acutis petiolis longissimis spathâ maximâ erectâ. *Arum without stalk, pointed spear-shaped leaves, with long foot-stalks, and a large upright spathe.* Arum venis albis Italicum maximum. H. R. Par.
3. **ARUM** (*Probofscidium*) acaule foliis hastatis spathâ declinatâ filiformi-subulatâ. Lin. Sp. Plant. 966. *Arum without stalk, spear-shaped leaves, and a declining awl-shaped spathe.* Arisarum flore in tenuem caudam abeunte. Tourn. Inst. 161. *Friers Cowl.*
4. **ARUM** (*Arisarum*) acaule foliis cordato-oblongis spathâ bifidâ spadice incurvo. Hort. Cliff. 435. *Arum without stalk, oblong heart-shaped leaves, a bifid spathe, and an incurved spadix.* Arisarum latifolium majus. C. B. P. 196. *Broad-leaved Friers Cowl.*
5. **ARUM** (*Tenuifolium*) acaule foliis lanceolatis spadice setaceo declinato. Hort. Cliff. 345. *Arum without stalk, spear-shaped leaves, and a bristly declining spadix.* Arisarum angustifolium Dioscoridis forte. Boerh. Ind. alt. 2-p. 73.
6. **ARUM** (*Virginicum*) acaule foliis hastato-cordatis acutis angulis obtusis. Hort. Cliff. 434. *Arum without stalk, pointed, spear, heart-shaped leaves, with obtuse angles.*
7. **ARUM** (*Triphyllum*) acaule foliis ternatis floribus monoicis. Flor. Virg. 113. *Three-leaved Arum without stalk.* Arum minus triphyllum arisarum pene viridi Virginianum. Mor. Hist. 3. p. 547.
8. **ARUM** (*Dracunculus*) foliis pedatis, foliolis petiolatis integerrimis æquantibus spatham spadice longiorem. Lin. Sp. Prod. Leyd. 7. *Arum with foot-shaped leaves, composed of spear-shaped, entire, equal lobes, and the spathe much longer than the spadix.* Dracunculus polyphyllus. C. B. P. 195. *Common Dragon.*
9. **ARUM** (*Dracontium*) foliis pedatis, foliolis lanceolatis integerrimis superantibus spatham spadice brevioribus. Prod. Leyd. 7. *Arum with foot-shaped leaves, the upper being composed of spear-shaped entire lobes, and the spathe shorter than the spadix.* Arum polyphyllum minus & humilius. H. L. 60.
10. **ARUM** (*Trilobatum*) acaule foliis sagittato trilobis flore sessile. Flor. Zeyl. 326. *Trifoliate Arum without stalks, and a flower growing close to the root.* Arum humile Zeylanicum latifolium pistillo coccineo. Hort. Amst. 1. p. 97.
11. **ARUM** (*Colocasia*) acaule foliis peltatis ovatis repandis basi semibifidis. Hort. Cliff. 434. *Arum without stalk, target-shaped oval leaves, waved and sinuated at their borders, and divided into two parts at their base.* Arum maximum Ægyptiacum quod vulgò Colocasia. Called Colocasia.
12. **ARUM** (*Betæ folia*) acaule foliis cordatis nervosis floribus sessilibus. *Arum without stalk, nervous heart-shaped leaves, and flowers without petals.* Arum Americanum betæ folio. Cateb. Hist. Car. 1. 71. Called *Scunk Weed.*
13. **ARUM** (*Divaricatum*) acaule foliis cordatis angulatis divaricatis. Lin. Sp. Plant. 966. *Arum without stalk, and heart-shaped angular leaves.* Arum acaule foliis subhastatis. Flor. Zeyl. 325.
14. **ARUM** (*Peregrinum*) acaule foliis cordatis obtusis mucronatis angulus rotundatis. Hort. Cliff. 435. *Arum without stalk, blunt heart-shaped leaves, which are pointed, and the angles rounded, called Edder in America.*
15. **ARUM** (*Esculentum*) acaule foliis peltatis ovatis integerrimis basi semibifidis. Hort. Cliff. 453. *Arum without stalk, oval target-shaped leaves, whose base are divided in two parts.* Arum minus nymphææ folio esculentum. Sloan. Cat. Jam. 62.

16. ARUM (*Sagittæ folium*) acaule foliis sagittatis triangularibus angulis divaricatis acutis. Hort. Cliff. 345. *Arum without stalk, lance-shaped leaves which are triangular, acute-pointed, and ribbed.* Arum maximum Ægyptiacum quod vulgò Colocasia cauliculis nigricantibus Zeylanica. H. L. B.

17. ARUM (*Arborefcens*) caulescens rectum, foliis sagittatis. Lin. Sp. 1371. *Arum with an erect stalk, and arrow-shaped leaves, commonly called Dumb Cane.*

18. ARUM (*Auritum*) caulescens radicans, foliis ternatis, lateralibus unilobatis. Lin. Sp. 1371. *Arum whose stalks send out roots, and trifoliate leaves.* Arum hederaceum triphyllum & auritum. Plum. Amer. 41. tab. 58.

The first sort grows naturally in woods and on shady banks in most parts of England, so is seldom admitted into gardens; but being a medicinal plant, it is here inserted to introduce the other species. There are two varieties of this, one with plain leaves, and the other hath leaves full of black spots, but these are only accidental varieties which arise from the same seeds. The roots of this are ordered by the College of Physicians to be used in a powder which bears the title of the plant; but these are generally gathered in the spring, when the leaves are in full vigour, so that the roots shrink and soon lose their pungent quality; but those which are taken up in August, when their leaves decay, will continue good a whole year, and retain their pungency the same as when first taken up. The not observing this, has brought the medicine into disrepute. It flowers in April, and the seeds ripen in July.

The second sort grows naturally in Italy, Spain, and Portugal, from whence I have received the seeds. The leaves of this sort rise a foot and a half high, are very large, running out to a point; these are finely veined with white, interspersed with black spots, which, together with the fine shining green of their surface, make a pretty variety. The flowers grow near a foot high, and have very long upright spathas, which are of a pale green, inclining to white; these appear the end of April, or beginning of May, and the seeds are ripe in August; this propagates very fast by offsets from the root, and will thrive in any soil or situation. The best time to transplant them is soon after the seeds are ripe, for by the end of October they will be putting out new fibres.

The third, fourth, and fifth sorts have been generally separated from this genus, and were distinguished by the title of Arisarum, or Friar's Cowl, from the resemblance the flower has in shape to the hoods or cowls worn by the people of that order; the leaves of these have short foot-stalks, the flowers growing close to the ground; they flower in April, but seldom produce seeds in England; however they multiply fast by offsets, and should have a shady situation. The time for transplanting the roots is the same as for the former. They are preserved in some gardens for the sake of variety, but have little beauty to recommend them.

The sixth and seventh sorts grow naturally in Virginia and Carolina, from whence I have received their roots; their leaves arise immediately from the roots, having scarce any foot-stalks; the flowers come up between their leaves, which have short foot-stalks; they appear in May, but have little beauty, so the plants are only kept in botanic gardens for the sake of variety. They will live in the open air, if they are planted in a sheltered situation, or if the surface of the ground is covered with tan to keep out the frost in winter, and will thrive better in the full ground than in pots. They are propagated by offsets.

The eighth sort is the common Dragon, which is used in medicine, and has been generally ranged in a separate genus from this under the title of Dracunculus, in which genus Tournefort has ranged all those species which have compound leaves, and those with single leaves he has placed under Arum.

This sort is used in medicine, so is preserved in gardens to supply the markets: it grows naturally in most

of the southern parts of Europe. This plant hath a large, tuberous, fleshy root, which, in the spring puts up a stait stalk about three feet high, which is spotted like the belly of a snake; at the top it spreads out into leaves, which are cut into several narrow segments almost to the bottom, which spread open like a hand; at the top of the stalk the flower is produced, which is in shape like the common Arum, having a very long spatha of a dark purple colour, standing erect, with a large pistil of the same colour, so that when it is in flower, it makes no unpleasing appearance; but the flower hath so strong a scent of carrion, that few persons can endure it; for which reason it hath been banished most gardens, but was it not for this, a few of the plants might merit a place in gardens, for the oddness of the flower. It is very hardy, so will grow in any soil or situation, and propagates very fast by offsets from the root. The time to transplant it is in autumn, when their leaves decay. It flowers in June or July, and their stalks decay in September.

The ninth sort grows naturally in moist places in Virginia and New England, but is very difficult to preserve long in a garden. I received some roots of this from New England a few years ago, which continued two years; but the soil being dry, they decayed in summer: these should have a moist shady situation, otherwise they will not thrive. The leaves of this sort are divided like those of the former, but are smaller, and rarely grow more than nine inches high; the flowers are like those of the common Arum, but the pistil is longer than the spatha. It flowers in June, and the stalks decay in autumn.

The tenth sort grows naturally in Ceylon, and some other parts of India, so is very impatient of cold: it is a plant of humble growth: the leaves come up from the root, having foot-stalks about four inches long; these are divided into three lobes, which terminate in points; the flower rises immediately from the root, standing on a very short foot-stalk; the spatha is long, erect, and of a fine scarlet within, as is also the pistil. This usually appears in May, and the leaves decay in August, but new ones soon after rise from the root. This plant must be placed in the tan-bed of the bark-stove, otherwise it will not thrive in England. It is propagated by offsets from the root, which come out in plenty when the plants are in health.

The eleventh, thirteenth, fourteenth, fifteenth, and sixteenth sorts, have mild roots, which are eaten by the inhabitants of all the hot countries, where they grow naturally, and some of the sorts are cultivated by the inhabitants of the sugar colonies, as esculent plants, their roots being constantly eaten, as also are the leaves of some of the sorts, particularly the fifteenth, which they call Indian Kale: the leaves of this are boiled, and supply the want of other greens. As there is a constant succession of these all the year, a small spot of ground, planted with these roots, will be sufficient to supply a large family. It is esteemed a wholesome green, and in those countries where many of the common European vegetables are with difficulty procured, this proves a good succedaneum; but they seem to make little distinction of the species, for I have received the roots of three sorts, by the common title of Edder; but I suppose the fourteenth sort is the most commonly cultivated there for their roots. The sixteenth sort has not been many years introduced among them, for it came originally from the Spanish West-Indies, where it grows in great plenty. Both these have larger roots than the fifteenth, for which reason they are preferred to it.

All these sorts are preserved in the gardens of those persons, who are curious in collecting exotic plants, for the variety of their leaves; their flowers have very little beauty, nor do they often appear in this country. The plants are propagated easily by offsets from their roots, which they put out plentifully: these must be planted in pots filled with light earth, and plunged into a hot-bed, to promote their taking root;

and if they are afterward continued in the bark-stove, they will make great progress, and their leaves will be larger. They may be kept in a dry stove, upon shelves, after they are well established in the pots, but they will not be so strong as the other.

The twelfth sort I was favoured with by Mr. Peter Collinson, F. R. S. who procured the root from North America, where it naturally grows. This requires a moist soil, and a shady situation, but is hardy in respect of cold. It flowered two years in the garden at Chelsea, but in a very dry season decayed. The flowers came up before there was any appearance of leaves; the spatha was large, and the pistil short and blunt; the female flowers were ranged each between a sort of cheque work, which was diagonal to the pistil; the flower decayed without any appearance of seed.

The seventeenth sort rises to the height of six or seven feet, with a green jointed stalk as large as a walking stick; the leaves are placed irregularly at the top of the stalks, growing in a cluster: these are oblong, and of a light green colour; from between the leaves the flowers come out on the side of the stalk, having a long spatha of a pale green colour, marked with white spots, sitting close to the stem of the plant; at their first appearance they stand erect, soon after they are horizontal, and in a little time they decline downward; their lower part is swelling so far as the flowers are ranged on the pistil, above which it is greatly contracted, and toward the top enlarges again, where it is a little open, so as to shew the naked part of the pistil, but is twisted again at the top. All the lower part closely folds over the pistil, so that it is scarce discernible, unless the spatha is opened, which can only be done on one side, the other adhering closely to the pistil, so far upward as the flowers extend the naked part of the pistil only being separated from it; so that the female flowers and stamina are ranged only upon one side of the pistil, in which it differs from all the other species which I have seen.

It grows naturally in the sugar islands, and other warm parts of America, chiefly in the low grounds; the whole plant abounds with an acrid juice, so that if a leaf or part of the stalk is broken, and applied to the tip of the tongue, it causes a very painful sensation, and occasions the salivary ducts to swell, and brings on a great defluxion of saliva; the stalks of this plant are sometimes applied to the mouths of the negroes by way of punishment, which is indeed bad enough. This sort is propagated by cutting off the stalks into lengths of three or four joints, which must be laid to dry six weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay: these should be planted in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tan, being careful that they have little wet, until they have made good roots; when they are well established at bottom, some of them may be placed in a dry stove, and others plunged into the tan-bed in the bark-stove, where they will make the greatest progress, and produce more flowers than the others. It is a tender plant, so must be constantly kept in the stove, and should have very little wet in winter.

The eighteenth sort is a scandent plant, sending out roots from the stem and branches, the leaves are large, heart-shaped, having three lobes or ears; the flowers are inclosed in a large spatha; but these are not fruitful in England. This is a tender plant, so requires to be constantly kept in the bark stove, and treated as other tender exotic plants, which come from hot countries. It is propagated by cutting off the branches, which readily put out roots, for all these species which are natives of hot countries, never produce seeds in England.

ARUM ÆTHIOPICUM. See CALLA.

ARUM SCANDENS. See DRACONTIUM.

ARUNDO. Lin. Gen. Plant. 76. The Reed.

The CHARACTERS are,

It is of the Grass tribe; the flowers grow in spikes, and

are included in a chaff which is oblong, pointed, and opens with two valves. The petals of the flowers are bivalve and longer than the empalement, having a down at their base, which rises almost their length; it hath three hairy stamina, crowned with horned summits; in the center is situated an oblong germen, supporting two slender styles which are hairy and reflexed, crowned with a simple stigma. The germen afterward becomes an oblong pointed seed, with long down adhering to its base.

This genus of plants is ranged in the second section of Linnæus's third class, entitled Triandria Digynia, the flowers having three stamina and two styles.

The SPECIES are,

1. ARUNDO (*Pbragmitis*) calycibus quinquefloris paniculâ laxâ. Prod. Leyd. 66. Reed with five flowers in each cup, growing in loose panicles. Arundo vulgaris palustris. J. B. 2. 485. The common Marsh Reed.
2. ARUNDO (*Donax*) calycibus trifloris paniculâ diffusâ. Prod. Leyd. 66. Reed with three flowers included in each cup, growing in diffused panicles. Arundo sativa quæ Donax Dioscoridis. C. B. P. 17. This is sometimes called by gardeners the Ever-green Reed, but for what reason I cannot imagine, because the stalks decay every autumn, and new shoots arise from the roots in the spring.
3. ARUNDO (*Verficolor*) Indica Laconica verficolor. Mor. Hist. 3. p. 219. Indian Reed with variegated leaves. Arundo Indica variegata seu Laconica Theophrasti. Cornut. Can. 55.
4. ARUNDO (*Bamboo*) calycibus multifloris, spicis ternis sessilibus. Lin. Sp. 120. Reed with many flowers in the cup, and sessile spikes, commonly called Bambu. Beesha. Hort. Mal. Vol. V. p. 119. and the Bambu altera species. Raii Hist. 1316.
5. ARUNDO (*Arborea*) caule arboreo foliis utrinque acuminatis. Reed with a tree-like stalk, and leaves which are pointed at both ends. Ily. Hort. Mal. Vol. I. p. 25.
6. ARUNDO (*Orientalis*) tenuifolia caule pleno ex quâ Turcæ calamos parant. Tourn. Cor. 39. Eastern Reed with a narrow leaf and a full stalk, of which the Turks make their writing pens.

The first sort is so very common by the sides of rivers and large standing waters in divers parts of England, that it is needless for me to say any thing of its culture. This is cut in autumn, when the leaves begin to fall, and the stems are changed brown, for making hedges in kitchen-gardens, and for many other uses.

The second sort, although native of a warm country, yet will bear the cold of our winters in the open ground, provided it is planted in a soil not too wet; and if the winter should prove very severe, a little mulch be laid over the roots; it dies to the surface in autumn, and rises again the succeeding spring; and if kept supplied with water in dry weather, will grow ten or twelve feet high the same summer; and is very proper to intermix with trees and shrubs, or tall plants and flowers in bosquets, where, by the oddness of its appearance, it will have a good effect, in adding to the variety. This is propagated by parting the roots early in the spring, before they begin to shoot, and will, in a year or two, if your ground be good, make very large stools, so that from each stool you may have eight or ten canes produced; but this never produces any spikes of flowers in England.

The stalks of this sort are brought from Portugal and Spain, and are used by the weavers, as also to make fishing-rods.

The third sort is supposed to be a variety of the second, differing therefrom only in having variegated leaves. But this I much doubt, because the sort with variegated leaves is much tenderer than the other, so must be sheltered from the frost, otherwise it will not live through the winter in England. The plant never grows to a third part of the height of the other, and the leaves are narrower and much shorter; whether these differences may not be occasioned by the weakness of the plant, I cannot take upon me to determine; for it is well known, that all those plants which have variegated leaves, are much weaker than the plain

plain, and do not grow so large, nor will they resist the cold so well. But as this is supposed to be a native of a different country, and by all the writers who have mentioned it supposed to be different, I have enumerated it among the species.

The two sorts of Bambu are of great service to the inhabitants of India, who make most of their common utensils of the stems of these canes, which grow to a prodigious magnitude in those countries.

We have plants of the fourth sort in the English gardens, which are more than twenty feet high; and if the stoves in which they are kept were high enough to admit them, they would, according to appearance, rise to twice that height. The shoots of this plant are of quicker growth than any other yet known, which rises with an upright stalk; for a strong shoot from the root will rise to twenty feet in five or six weeks, as I have for several years observed. Some of these stems are as large as a man's wrist, but in general as big as walking-sticks, and when dried are as fit for that purpose as those which are imported. The leaves of this sort are much broader than those of the fifth, particularly at their base; these leaves are generally put round the tea-chests in their package, and are fastened together so as to form a kind of mat.

The fifth sort is more rare at present in Europe, tho' it is the most common on the coast of Malabar.

They are both tender plants, so will not live in this country, unless they are preserved in a warm stove; and as their roots spread very wide, they should not be confined: therefore to have them produce strong stems, they must be planted in large tubs, filled with rich earth, and plunged into the hot-bed in the bark-stove; and as they naturally grow in marshy low places, they require plenty of water, especially when the roots have filled the tubs in which they were planted. When the tubs decay, the boards may be removed, and the plants permitted to root into the tan, which will encourage them to grow to a larger size; but then there must be care taken when the bed is refreshed with new tan, to leave a sufficient quantity of the old tan about the roots of the plants; for if they are too much bared, and the new tan laid near them, when that heats, it will scorch their roots so that the plants are sometimes destroyed by it. Both sorts are propagated by slips from the roots, which should be taken off in the spring, that they may be well established before the winter.

The sixth sort is what the Turks make their writing pens withal; this grows in a valley near mount Athos, as also on the banks of the river Jordan, but there are none of the plants in England. This sort may be managed as the Bambu.

ARUNDO SACCHARIFERA. See SACHARUM.

ASARINA. Tourn. Inst. R. H. 171. tab. 76. Bastard Asarum.

The CHARACTERS are,

The empalement is of one leaf, which is cut into five equal segments almost to the bottom. The flower is of one leaf, of the grining kind, having a long cylindrical tube, divided at the top into two lips, the upper one being divided into two parts, whose edges are reflexed. The lower lip is slightly cut into three parts which are obtuse; the two lips join close together, so as to form a kind of snout. It hath four stamina, two of which are longer than the other; in the center is placed a round germen supporting a single style, crowned by an obtuse stigma. The germen afterward turns to a round husk, divided into two cells, which are full of roundish seeds.

This genus of plants is by Dr. Linnæus joined to his genus of Antirrhinum, which is ranged in the second section of his fourteenth class, titled Didynamia Angiospermia, the flowers having two long and two shorter stamina, and the seeds having a capsule.

The SPECIES are,

1. ASARINA (*Procumbens*) caule decumbente foliis oppositis reniformibus crenatis. Bastard Asarum with a trailing stalk, and kidney-shaped leaves growing opposite,

which are indented on their edges. Asarina hederula faxatilis. Lob. Icon. 601. Asarina, or Rock Ground-ivy.

2. ASARINA (*Erecta*) caule erecto foliis lanceolatis amplexicaulibus paniculâ dichotomâ. Upright Bastard Asarum with spear-shaped leaves which embrace the stalks, and spikes of flowers coming out from the division of the branches. Penstemon. Mitch. Gen. 14.

The first sort is a low trailing annual plant, the branches extend little more than a foot each way, and are weak, so that unless they are supported, they lie upon the ground; these are garnished with leaves like those of Ground-ivy, which grow by pairs; at the wings of the leaves the flowers come out singly on each side the stalk, which are shaped like those of Snap-dragon, but have a long tube; they are of a worn-out purple colour at the top, but below of an herbaceous colour. These come out in June, and the seeds ripen in September, which should be sown soon after, or permitted to scatter, for when they are sown in the spring they seldom grow. The plants should remain where they are sown, and require no other care but to keep them clean from weeds, and thin them where they grow too close. As there is not much beauty in this plant, two or three of them will be enough in a garden, for the sake of variety. It grows naturally in Italy and the south of France.

The second sort grows naturally in North America. This plant hath upright stalks, which grow a foot and a half high, and put out several side branches, garnished with oblong spear-shaped leaves ending in a point, which grow opposite, and embrace the stalks at their base; the flowers come out in short loose spikes from the divisions of the stalks, which are shaped like those of the former, but are less, and of a purple colour. They appear in June and July, and their seeds ripen in September.

The seeds of this sort should be sown in the autumn; for those which are sown in the spring, seldom grow the same year, but remain in the ground till the following spring. When the plants are grown strong enough to remove, they should be transplanted into a shady border, which will prevent their flowering the same year; and in the autumn they may be planted in the borders of the flower-garden, where they will add to the variety. The roots seldom last above two or three years, so that young plants should be annually raised.

ASARUM [from a privative, and *Caſew*, Gr. to adorn, as much as to say, a plant not fit for ornament,] Asarabacca.

The CHARACTERS are,

The flowers hath a thick bell-shaped empalement of one leaf, which is coloured, and slightly cut at the brim into three parts, which are reflexed. It hath no petals, but twelve short awl-shaped stamina, crowned by oblong summits, which are fastened in the middle to the stamina; at the bottom of the empalement is inclosed a thick germen, supporting a short cylindrical style, crowned by a reflexed stigma, cut into six parts. The germen afterward turns to a thick capsule having six cells, containing several oval seeds.

This genus of plants is ranged in Linnæus's eleventh class, entitled Dodecandria Monogynia, the flowers having twelve stamina and one style.

The SPECIES are,

1. ASARUM (*Europæum*) foliis reniformibus obtusis binis. Lin. Sp. Pl. 442. Asarabacca with kidney-shaped leaves, which have two blunt points. Asarum. C. B. P. 197. Common Asarabacca.
2. ASARUM (*Canadense*) foliis reniformibus mucronatis. Lin. Sp. Plant. 442. Asarabacca with kidney-shaped leaves ending in a point. Asarum Canadense. Cornut. Canad. 24. Canada Asarabacca.
3. ASARUM (*Virginicum*) foliis cordatis obtusis glabris petiolatis. Flor. Virg. 162. Asarabacca with smooth, blunt, heart-shaped leaves having foot-stalks. Asarum Virginianum pistolochiæ foliis subrotundis cyclaminis more maculatis. Pluk. Alm. 53.

The

The first sort hath thick fleshy roots which are jointed, and send out fibres from every part; the leaves grow singly upon short foot-stalks, arising immediately from the root; these are kidney-shaped, eared at the foot-stalk, and rounded at the top, where they are indented; they are smooth, and of a shining green colour: the flowers grow upon very short foot-stalks close to the ground, so are hid under the leaves. They are composed of a bell-shaped empalement, of a worn-out purple colour, which is cut into three at the top, where it turns backward: in the bottom is situated the germen, attended by twelve short stamina, which afterward turns to a leathery seed-vessel, divided into six cells, which contain several roundish seeds.

The leaves of the second sort are much larger than those of the first, and stand on longer foot-stalks; these are pointed and hairy. The flowers are like those of the other sort, growing close to the root, but are somewhat inclining to green on their outside, in all other respects they agree.

The third sort hath smooth blunt heart-shaped leaves, standing on longer foot-stalks; these are veined and spotted on their upper surface like those of the autumnal Cyclamen; the flowers of this are shaped like the others, but stand on longer foot-stalks, and are of a darker purple colour. These flower in April and May, and their seeds ripen in July and August.

The first of these sorts is very common, and hath been found wild in some parts of England, though but rarely; it delights in a moist shady place, and is increased by parting the roots in autumn. This is the sort which is used in medicine.

The Canada sort is equally hardy, so will endure our common winters in the open ground, being rarely hurt by frosts, if planted in a dry soil, for too much wet often occasions the roots to rot in winter. This is propagated as the other.

The third sort will also live in the open air in England, being seldom injured by frost; but if the plants are too much exposed to the sun in summer, they seldom thrive well; therefore they should be planted in a border where they may have only the morning sun, in which situation they will spread and increase. These two last grow naturally in several parts of North America.

ASCLEPIAS [so called from *Æsculapius* the first inventor of physic; it is also called *Vincetoxicum*, from *vincere*, to overcome, and *τοξικά*, poisons, q. d. a plant overcoming poisons,] *Hirundinaria*, or *Swallow-wort*.

The CHARACTERS are,

The empalement is of one leaf, which is cut into five acute segments; the petal of the flower is also of one leaf, divided into five oval parts, which are reflexed; in the center is situated five nectarii which encompass the parts of generation; these have horns which turn toward the stamina, and are joined in a truncated body inclosed by five scales, which open every way. There are five stamina which are scarce visible, which have five summits, situated between the nectarii, and inclosed by the scales of the truncated body. It hath two oval pointed germen, supporting two short styles crowned by a single stigma. The germen afterward becomes two large, oblong, swelling pods ending in a point, having one cell, which opens with two valves filled with compressed seeds, lying over each other like tiles on a house, and are crowned with a soft down.

This genus of plants is ranged in *Linnaeus's* second section of his fifth class, entitled *Pentandria Digynia*, the flowers having five stamina and two styles.

The SPECIES are,

1. **ASCLEPIAS** (*Alba*) foliis ovatis basi barbatis caule erecto umbellulis proliferis. *Lin. Sp. Plant.* 314. *Swallow-wort with oval leaves bearded at their base, an upright stalk, and a proliferous umbel.* *Asclepias albo flore.* C. B. P. 303.

Sp. Plant. 215. *Swallow-wort with smooth spear-shaped leaves, having foot-stalks, a single stalk, and upright single umbels.* Apocynum radice fibrosa, petalis coccineis corniculis croceis. Hort. Elth. 34. commonly called *Bastard-Ipecacuanza*.

18. ASCLEPIAS (*Gigantea*) foliis amplexicaulibus oblongo-ovalibus. Flor. Zeyl. 112. *Swallow-wort with oblong, oval leaves, embracing the stalks.* Apocynum erectum majus latifolium Indicum. Pluk. Alm. 35. tab. 175. f. 3.

19. ASCLEPIAS (*Scandens*) foliis oblongo-lanceolatis sub-hirsutis caule fruticoso scandente umbellis lateralibus congestis. *Swallow-wort with oblong, spear-shaped, hairy leaves, a shrubby climbing stalk, and compact umbels proceeding from the side.*

The first sort is the common Swallow-wort of the shops. This is called Vincetoxicum & Hirundinaria, in English Swallow-wort, or tame poison, from its supposed virtue, being accounted a mighty counter poison. The root is the only part which is used: it is composed of many strong fibres, which are connected at the top, like those of Asparagus, from which arise many foot-stalks, in number proportional to the size of the roots; which grow near two feet high, are very slender at the top; the leaves are oval, ending in a point, and placed by pairs. The flowers are white, growing in umbels near the top of the stalk, from which are sent out smaller umbels; the flowers are of one leaf, cut into five parts, in the center of which are placed five horned nectarii, among which the stamina and styles are situated. After the flower is past, the two germen become two long pointed pods, inclosing many compressed seeds, which are crowned with a soft white down. The flowers appear in June, and the seeds ripen in September. This sort grows naturally in the south of France, Spain, and Italy.

The second sort agrees with the first, in the shape of its roots, leaves, and flowers, but the stalks extend to a greater length, and toward their upper part twist round any sticks, or other plants near them, and the flowers of this are black. This flowers at the same time with the first, and seldom fails to ripen its seeds in England.

The third differs from both the other in the narrowness of its leaves, and weakness of its stalks; the umbels of flowers are single, and of a yellow colour. This flowers at the same time with the two former sorts, and generally perfects seeds in England. There is a variety of this with broader leaves, which may have come from the seeds of this.

These plants are common in the English gardens, and natives of the same countries. They are generally propagated by parting their roots, especially the first sort, which seldom produces seeds in England. The best time for this is in autumn, when their stalks begin to decay. They should not be planted nearer together than three feet, for the fibres of their roots extend to a considerable distance. They are very hardy plants, so will thrive in any situation, but love a dry soil. Their stalks die in autumn, and new ones rise in the spring.

The fourth sort grows naturally in North America; this rises with slender upright stalks, garnished with very narrow leaves, growing in whorles round the stalks, at the top of which grow umbels of small, white, starry flowers. These appear in July, but are never succeeded by pods in England, so are only propagated by parting their roots; which should be done in the spring, before they put out new shoots. The roots should be planted in a warm border and dry soil, and in winter covered with old tan, to prevent the frost from penetrating the ground.

The fifth sort creeps greatly at the root, so that it will soon spread over a large spot of ground; this sends up strong stems upward of four feet high, which have thick oval leaves placed opposite, hoary on their under sides. Toward the top of the stalks the umbels of flowers come out on the side; these are of a worn-out purple colour, smelling sweet, and nod

downward; sometimes these are succeeded by large oval pods, filled with flat seeds, crowned by a long soft down; it flowers in July. This propagates fast enough by its creeping root, and will grow in any soil or situation. It may be transplanted any time after the stalks decay, or before the roots shoot in the spring.

The sixth sort hath a perennial root, which sends up several upright stalks in the spring, about two feet high, garnished with oval leaves growing opposite; at the top of the stalks the umbels of flowers are produced, which are of a bright purple colour, making a pretty appearance in July, but are not succeeded by pods in England; this must be treated as the fourth sort. I was favoured with this by Mr. Peter Collinson, F. R. S.

The seventh sort grows naturally in North America. This hath a perennial root, which sends out single stalks near three feet high, garnished with oval leaves, hairy on their under side, placed opposite; the flowers grow in erect umbels at the top, and the nectarii are declining. They are of a worn-out purple colour resembling those of the fifth; it is very hardy, and propagates fast by its creeping roots, but never produces seeds in England. This will grow in any soil or situation, and may be transplanted when the stalks decay.

The eighth sort resembles the seventh, but the leaves are rough, and the umbels of flowers are more compact, and come out on the side of the stalk; these are of an herbaceous colour, and are not succeeded by pods in this country, but is propagated by roots as the former sort.

The ninth sort came first from Canada, but hath since been found growing naturally in several other parts of America. This hath a perennial root, which puts out several upright stalks about two feet high, which have oblong smooth leaves placed by pairs; at the top are produced close umbels of purple flowers; these appear in August, but are not succeeded by seeds here, so is only propagated by parting the roots, which do not increase very fast, therefore the plant is not very plenty in the gardens; it is hardy enough to live abroad, if it is planted in a dry soil.

The tenth sort is a native of North America, but is hardy enough to live abroad in England, if it is planted in a warm situation and a dry soil. This hath declining stalks, which are hairy, a foot and a half long; the leaves are narrow, hairy, and placed opposite; the umbels grow at the extremity of the branches, which are compact, the flowers are of a bright Orange colour. It is propagated by seeds, which should be sown in pots, and plunged into a moderate hot-bed to bring up the plants, which should be inured to the open air so soon as the weather will permit; for if they are drawn up weak, they seldom recover it. When they are of a proper strength to remove, they should be shaken out of the pots, and planted in a warm border six inches asunder, being careful to shade them from the sun until they have taken fresh root, but they must have very little water given them, for they are milky plants, which rot with much wet. During the summer they must be kept clean from weeds, and when their stalks decay in autumn, some rotten tan should be laid over the ground to keep out the frost, which should be removed in the spring before the plants put out new shoots; the following summer they will require no other care than before, and also the next winter they must be covered as in the former. The second spring the roots may be transplanted where they are to remain; the roots will then be strong enough to flower in summer, and will last several years, especially if they are covered with tan to keep out the frost, but they should not be afterward removed; for when the roots are large, they will not bear transplanting.

The eleventh sort is a native of the same countries, and is much like the former, but differs in having upright stalks, and the leaves growing alternate. The roots of this grow to a large size, so will not bear

A a trans-

transplanting after the plants are two years old. It is propagated by seeds, which should be treated in the manner directed for the former. These flower the latter end of July and in August; and in warm seasons, sometimes ripen their seeds in England. Neither of these plants will live long in pots, for which reason I have recommended their being planted in the full ground; but they should have a warm situation.

The twelfth, thirteenth, and fourteenth sorts grow naturally at the Cape of Good Hope. I have also received seeds of the thirteenth sort from Alexandria; and Mr. Peter Collinson, F. R. S. gave me some seeds of it, which were sent him from Minorca; but it is not certain that it grows naturally there, but may have been carried thither from Africa.

These rise with upright shrubby stems to the height of seven or eight feet, and divide into many branches; those of the twelfth sort are garnished their whole length with long, narrow, smooth leaves, ending in a point; from the wings of the leaves the umbels of flowers are produced, upon long foot-stalks; the flowers are white, and grow loosely on the umbel; these are frequently succeeded by short, thick, swelling pods, ending in a point, which are thick set with hairs, and filled with compressed seeds, crowned with a soft down. This flowers from June to October, and the seeds ripen in winter.

The thirteenth sort differs from the twelfth, in having much broader leaves, which are of a darker green; the umbels of flowers are smaller, grow upon shorter foot-stalks, and the single flowers are larger. This flowers at the same time with the former.

The fourteenth sort doth not rise so high as either of the former, and the branches grow at a much greater distance; the leaves are shorter, and are covered on both sides with short hairs. The flowers grow in small loose umbels, and are white; these appear in the same season with the former.

These are propagated by seeds, which may be sown in April on a bed of light earth in the open air, and when the plants are three or four inches high, they should be each planted in a small pot filled with light earth, and shaded until they have taken new root, then they may be placed with other exotic plants in a sheltered situation till October, when they must be removed into the green-house, and during the winter should have but little water; for as they abound with a milky juice, much wet will rot them. The only care these will require, is to shift them into larger pots as they advance in their growth; but care should be taken not to put them in pots too large, and in the summer to place them abroad with other plants from the same country.

These three sorts may also be propagated by cuttings, which if planted in July or August, in a shady border, will soon take root, and may soon after be taken up and planted in pots, and managed as the seedling plants. The thirteenth sort hath lived in the open air in mild winters in the Chelsea garden, but in cold winters they are constantly destroyed.

The fifteenth sort grows with an upright shrubby stalk to the height of six or seven feet, dividing toward the top into three or four branches, garnished their whole length with stiff roundish leaves, which closely embrace them. Toward the upper part, the flowers are produced on their sides, growing in short compact umbels. These are of an herbaceous colour, so make but little appearance; they come out chiefly in autumn and winter. This grows naturally at the Cape of Good Hope, and requires the same culture as the former sorts. There is a variety of this with deep green leaves, which some have supposed to be a different species, but I have raised it from the same seeds. The sixteenth sort grows naturally in the warm parts of America, the seeds were sent me from La Vera Cruz. This rises with single stalks four feet high, garnished with smooth spear-shaped leaves, ending in a point; toward the top of the stalk the umbels of flowers are produced from the wings of the leaves,

which are white, and stand erect; these are succeeded by oblong pointed pods, filled with compressed seeds, crowned with soft down. It flowers in June and July, and the seeds ripen in October.

This plant is tender, so must be raised in a hot-bed, and transplanted into pots filled with rich earth, and plunged into the tan-bed in the stove. It must have but little water, and constantly remain in the stove, otherwise the plants will not thrive here.

The seventeenth sort is also a native of the warm parts of America, the roots of which have been sent to England for Ipecacuana, from which it may be easily distinguished by its form, this being composed of a great number of small fibres; whereas the true Ipecacuana hath jointed roots, which run deep into the ground, and are fleshy. There have been many accounts of the bad effects of the use of these roots, as also of the poisonous quality of the plant; so that the public should be cautioned not to make use of it, and also to be careful not to let the milky juice of the plant mix with any thing which is taken inwardly.

This plant rises five or six feet high, with upright stems, garnished with smooth oblong leaves, placed opposite; toward the top of the branches the umbels of flowers come out, which are single, and grow erect; the petals of the flowers are of a scarlet colour; and the horny nectarii in the middle are of a bright Saffron colour, which make a pretty appearance; there is commonly a succession of these flowers on the same plant from June to October. The flowers are succeeded by long taper pods filled with seeds crowned by a soft down, which ripen late in the autumn.

It is propagated by seeds, which must be sown on a hot-bed in the spring, and the plants should be treated in the same manner as is before directed for the former sort; the roots of this may be continued three or four years, but after the second year the plants grow naked, and do not produce so many flowers as before; so that it is much better to raise young plants to succeed the other, especially as they produce plenty of seeds in England.

The eighteenth sort rises with upright stems six or seven feet high, which are garnished with thick oval leaves placed opposite. The umbels of flowers are single; the flowers are white, of a star figure, having five points; the pods of this sort are very large, in shape like an ox's testicles, and are filled with flat seeds, lying over each other like tiles on a house. I received the seeds of this sort from the Right Hon. the Earl of Northumberland, who procured it from India.

This plant is tender, so must be preserved constantly in the stove, and treated in the same manner as the two former sorts, and should have very little wet, especially in the winter.

The nineteenth sort I received from Carthage; this hath climbing stalks, which fasten themselves to the neighbouring plants, and rise to the height of ten or twelve feet; the joints of the stalks are pretty distant from each other; at each are produced two oblong, spear-shaped, hairy leaves, growing opposite, upon very short foot-stalks; the umbels of flowers come out from the wings of the leaves, which are very compact, and the flowers are of a sulphur colour. These appear in August, but have not been succeeded by seeds in England.

This plant is tender, so must be constantly preserved in the stove, and treated in the same way as is directed for the former sorts.

A S C Y R U M. Lin. Gen. Plant. 737. Hypericoides. Plum. Nov. Gen. 51. tab. 7. St. Peterwort.

The CHARACTERS are,

The empalement is four leaved, the two outer being narrow and opposite, the two inner are broad, heart-shaped, and erect. The flower hath four oval petals, the two outer are large and placed opposite, the two inner are small. In the center is situated an oblong germen, with a very short style, crowned by a single stigma. This is attended by a great number of bristly stamina, which are joined

joined at their base into four bodies, and are crowned with round summits. The germen afterward becomes an oblong pointed seed-vessel, opening in two valves, and filled with small round seeds. The seed-vessel is inclosed by the two large leaves of the empalement.

This genus of plants is ranged in the third section of Linnæus's eighteenth class, entitled Polyadelphia Polyandria, the flowers having many stamina, which are joined in several bodies.

The SPECIES are,

1. ASCYRUM (*Cruæ Andree*) foliis ovatis caule tereti paniculâ dichotomâ. Lin. Sp. Plant. 787. *St. Peterwort with oval leaves, a taper stalk, and flowers growing in loose spikes from the divisions of the branches.* Hypericoides ex terrâ marianâ floribus exiguis luteis. Pluk. Mant. 104. called *St. Andrew's Cross*.
2. ASCYRUM (*Villosum*) foliis hirsutis caule stricto. Lin. Sp. Plant. 788. *St. Peterwort with hairy leaves and a stiff slender stalk.* Hypericum Virginianum frutescens pilosissimum. Pluk. Alm. 189.
3. ASCYRUM (*Hypericoides*) foliis oblongis, ramis ancipitibus. Lin. Sp. 1108. *St. Peterwort with oblong leaves and a flattened stalk.* Hypericoides frutescens erecta flore luteo. Plum. Nov. Gen. 51.

The first sort is a low plant, whose stalks seldom rise more than six inches high, garnished with small oval leaves, placed by pairs; the stalks are slender, and divide into two toward the top. From between the division of the branches, the loose spikes of yellow flowers are produced very small, so make no appearance; therefore the plant is scarce worthy of a place in gardens, except for the sake of variety. The root is perennial, and the plant may be propagated by laying down its branches; it loves a moist soil and a shady situation. This grows naturally in North America; I was favoured with this plant by the Right Hon. the Earl of Northumberland, who procured it from thence.

The second sort grows about three feet high, with upright stalks, garnished with hairy oblong leaves; the flowers are produced at the ends of the stalks, which are of the shape and colour with common *St. Johnswort*, but have only four leaves. This hath a perennial root, but the stalks decay every autumn. It may be propagated by parting the roots in autumn, when the stalks decay, and should be planted in a loamy soil; this some years will produce seeds in England. It grows naturally in Virginia.

The third sort grows naturally in South Carolina, from whence I received the seeds. This plant rises a foot and a half high, with flat stalks, garnished with oval smooth leaves growing opposite; the stalks are terminated by three or four yellow flowers, growing close together, which are larger than those of the common *St. Johnswort*, and the petals of the flowers are hollow. This sort rarely produces seeds in England, but it may be propagated by cuttings made of the young shoots in May, which, if planted in pots, and plunged into a very moderate hot-bed, will take root in five or six weeks, when they may be transplanted into a warm border, where they will endure the cold of our ordinary winters; but in severe frosts they are frequently destroyed, unless the roots are covered with tan to keep out the frost.

These plants have little beauty, so are seldom cultivated but in botanic gardens for the sake of variety.

ASCYRUM BALEARICUM. } See HYPERI-
ASCYRUM MAGNO FLORE. } CUM.
ASCYRUM VULGARE. }

ASH-TREE. See FRAXINUS.

ASHES are esteemed a good superficial dressing for corn and meadow land, as they give a new ferment to such lands as are in any degree sluggish and inactive, and enrich those which are jejune and slow, being endowed with singular qualities to make them prolific.

All sorts of ashes, indeed, contain in them a very rich fertile salt, and are the best manure of any to lay upon cold wet land; but then they ought to be kept dry, that the rain may not wash away their salt. Ex-

perience has shewn, that the ashes of any sort of vegetable are very advantageous to land, by the improvement that has been made in most places in England, by burning bean-stalks, fern, furze, heath, sedge, straw, stubble, &c.

Coal ashes, or such as are made of Newcastle, Scotch, and other pit-coal, are much recommended by some; but the first are most approved of, because they contain a greater quantity of nitrous and sulphureous matter than the others, though the rest are good.

There is no dressing so good for grass ground as the sea-coal ashes, especially for cold wet land, and where it is subject to rushes or moss; for these will destroy both, and occasion the grass to be much finer: but this dressing should be laid on the land early in winter, otherwise they will do harm the first summer; for when they are laid on the ground in the spring, they will cause the grass to burn as soon as the warmth comes on; whereas those that were put on early enough to receive the winter's rain, will be washed into the ground before the warm season, whereby the grass will have the benefit of it the first year. Where the land is poor and sour, producing rushes and moss only, there should be at least twenty loads of ashes laid upon each acre; for a slight dressing will not answer the design of killing weeds and moss, nor will it be sufficient to enrich land which is cold and sluggish, therefore it will be better to lay a good dressing at first, than to do it at several intervals; for one substantial dressing will continue the land longer in heart than three slight ones, besides the advantage before-mentioned.

But these ought to be applied superficially, and not too near the roots of plants; and if so, there are few plants but will receive benefit by them, by their nitrous and sulphureous qualities being washed down by the rain, which will open by the strength of water, and cause it to heave, in some degree, as lime will do when water is thrown upon it.

Wood-ashes are commended as the principal of superficial dressings for land, in that they contain a vegetative kind of salt.

Kiln-ashes, i. e. such as are made of straw, furze, &c. are, by some, accounted as good as any of the spirituous improvements of lands that are lightish; but for such as are heavy, they are looked upon as scarce solid and ponderous enough. These ashes the maltsters in the west country sift over their corn and grass, which are supposed, by their heat, to cause a fermentation, a hollowness and looseness in the mould; by which means the rains enter it the more easily, and dispose the earth for giving up an assumption of its vegetative augment.

But these being light, ought never to be strewed nor sifted in windy weather, because they would be blown away; and if it could be so ordered as to be done just before snow or rain, it would be the better.

Soap-ashes (i. e. after the soap-boilers have done with them) are very proper for lands that are very cold and sour, and to kill weeds of all sorts: and Sir Hugh Plat mentions one at Ware, who having a piece of land over-run with broom and furze, manured it with soap-ashes, and had an incredible crop of wheat for six years successively.

Pot-ashes, after the pot-ash men have done with them, are esteemed good for most sorts of land; but as they have been wet, and most of the salt drawn off by the lee, they ought to be laid on much thicker than other ashes.

Turf-ashes are very good for all sorts of land, but especially for clay lands, but will be much better if mixed with lime.

But all these ashes ought to be kept dry, from the time they are made till they are used, else the rains will both wash away their goodness, and also make them clod, especially some of the last mentioned, which will prevent their spreading.

And besides, one load of ashes that has been kept dry, will go as far as two that have been exposed to the rain: and coal-ashes, if moistened with cham-

chamber-lye or soap-suds, will greatly add to their strength.

All calcined vegetables cause a fiery heat and vegetation, and, when wet comes, set the ground to work, by a subtle insinuation unlocking the clods, and quickening the sluggishness of the earth, according to that established maxim among naturalists, That all fermentation is caused by the interposition or mixture of different qualities one with the other.

It is after this manner that coal-ashes operate so admirably in loosening and mouldering stiff clayey grounds, and, as it is usually termed, making it rough, ashy, or sandy-like: and after the same manner, sand mixed with clay does well, especially when it is impregnated with saline qualities.

ASPALATHUS. Lin. Gen. Plant. 767. African Broom.

The CHARACTERS are,

The empalement is of one leaf, which is cut into five equal segments at the top; the flower is of the butterfly kind. The standard is hairy, compressed, and blunt-pointed; the wings are blunt, moon-shaped, and spread open, being shorter than the standard; the keel is bifid, and of the same length as the wings. It hath ten stamina, nine of which are joined and covered by the standard, the other standing separate; these are crowned by oblong single summits. In the bottom is situated an oval germen supporting a single style, crowned by a pointed stigma. The germen afterward becomes an oval oblong pod, inclosing one or two kidney-shaped seeds.

This genus of plants is ranged in the third section of Dr. Linnæus's seventeenth class, entitled Diadelphia Decandria, the flowers having ten stamina joined in two bodies.

The SPECIES are,

1. ASPALATHUS (*Chenopoda*) foliis confertis subulatis mucronatis hispidis floribus capitatis. Lin. Sp. Plant. 711. *Aspalathus with rough, pointed, awl-shaped leaves, growing in clusters, and flowers in heads. Genista Africana lutea, floribus hirsutis in capitula lanuginosa conglobatis foliis corrodæ aculeatis subhirsutis. Herm. Cat. 11. Yellow African Broom.*
2. ASPALATHUS (*Indica*) foliis quinatis sessilibus pedunculis unifloris. Lin. Sp. Plant. 712. *Five-leaved Aspalathus growing close to the branches, and one flower on a foot-stalk. Dorycnium Indicum floribus singularibus rubris in pedicellis oblongis siliquis perexiguus. Raii Supp. 471.*
3. ASPALATHUS (*Argentea*) foliis trinis linearibus sericeis stipulis simplicibus mucronatis floribus sparsis tomentosis. Lin. Sp. Plant. 713. *Aspalathus with three narrow silky leaves, single-pointed stipule, and woolly flowers growing thinly. Cytisus Africanus angustifolius sericea lanugine argentatus spicâ lagopoide. Pluk. Mat. 63.*

These plants grow naturally about the Cape of Good Hope, from whence I have received their seeds. The first is a low shrub growing about three feet high, with slender branches, garnished with many trifoliate leaves growing in clusters, which are awl-shaped, pointed, and rough; at the ends of the branches the flowers come out, which are yellow, collected in woolly heads; these are rarely succeeded by pods in England. It is propagated by seeds, which must be obtained from the country where the plants grow naturally, and should be sown in pots filled with light earth as soon as they arrive: if this happens in the autumn, the pots should be plunged into an old tan-bed whose heat is spent, where they may remain till spring, when they should be removed into a moderate hot-bed, which will bring up the plants. But when the seeds arrive in the spring, the pots in which the seeds are sown should be then plunged into a moderate hot-bed; and in warm weather the glasses must be shaded in the middle of the day, and the pots frequently refreshed with water. Those seeds which are sown in the spring, seldom grow the same year, therefore in the autumn the pots should be put into an old tan-bed, as was directed for those sown in autumn, and afterward put in a hot-bed the following spring.

When the plants come up, and are strong enough to remove, they should be each planted into a separate small pot filled with light earth, and plunged into a moderate hot-bed, to encourage their rooting again; and so soon as they are established in the pots, they should by degrees be inured to the open air, into which they should be removed in summer, placing them in a sheltered situation, where they may remain till autumn, when they must be carried into the green-house, and in winter should have but little water.

The second sort grows about five feet high, with slender branches, garnished with leaves growing by fives close to the branches; the flowers come out singly upon long foot-stalks, which are of a pale red colour; these appear in August, but seldom are succeeded by pods here. This is propagated as the former, and requires the same treatment.

The third sort rises about four feet high, with a shrubby stalk dividing into slender branches, garnished with silky leaves, coming out by threes; the flowers are purple, downy, and grow thinly on the branches. This is propagated as the two former, and must be treated in the same way as is directed for the first sort. It flowers late in the summer.

ASPARAGUS, the first sprigs of herbs before unfolded into leaves, and the youngest and tenderest branches that are eatable, are called Asparagus.

ASPARAGUS [*Ἀσπάραγος*, Gr. signifies a young shoot putting forth,] Asparagus, Sparagus, corruptly called Sparrowgrafs.

The CHARACTERS are,

There are male and hermaphrodite flowers upon different roots; the male flowers are tubulous, composed of six narrow petals, which do not spread open, having six short stamina, but no style or stigma; these are barren: the hermaphrodite flowers have six petals which spread open, six stamina surrounding the germen, and a short style crowned by an obtuse stigma which is prominent. The germen afterward becomes a round berry, having three cells, each including one or two seeds, rounded on their outside, but angular where they join.

This genus of plants is ranged by Dr. Linnæus in the first section of his sixth class, titled Hexandria Monogynia, but with more propriety should be placed in the second order of his twenty-first class, which includes those plants as have the Polygamia on different roots.

The SPECIES are,

1. ASPARAGUS caule herbaceo erecto, foliis setaceis, stipulis duabus interioribus, una exteriorc. Flor. Suec. 272. *Asparagus with an upright herbaceous stalk, bristly leaves, having two inner and one outer stipula. Asparagus sativa. C. B. P. 489. Garden Asparagus.*
2. ASPARAGUS (*Maritimus*) caule inermi herbaceo foliis teretibus longioribus fasciculatis. *Asparagus with a smooth herbaceous stalk, and longer taper leaves growing in clusters. Asparagus maritimus crassiore folio. C. B. P. 490.*
3. ASPARAGUS (*Acutifolius*) caule inermi fruticoso, foliis aciformibus rigidulis perennantibus mucronatis aequalibus. Lin. Sp. 449. *Asparagus with a shrubby smooth stalk and rigid leaves, with points which abide in winter. Asparagus foliis acutis. C. B. P. 490.*
4. ASPARAGUS (*Albus*) spinis retroflexis, ramis flexuosis, foliis fasciculatis angulatis muticis deciduis. Lin. Sp. 449. *Asparagus with flexible branches and chaffy leaves growing in clusters, which fall off in winter. Asparagus aculeatis spinis horridus. C. B. P. 490.*
5. ASPARAGUS (*Retrofractus*) aculeis solitariis ramis reflexis retrofractisque, foliis fasciculatis. Lin. Sp. Plant. 313. *Asparagus with single spines, reflexed branches, and leaves growing in clusters. Asparagus Africanus tenuifolius, viminalibus virgis, foliis laricis ad instar ex uno puncto numerosis stellatim positis. Pluk. Alm. 40. tab. 375.*
6. ASPARAGUS (*Aphyllus*) aphyllus spinis subulatis striatis inæqualibus divergentibus. Hort. Cliff. 122. *Asparagus without leaves, and awl-shaped unequal spines which spread from each other. Asparagus aculeatus alter,*

alter, tribus aut quatuor spinis ad eundem exortum. C. B. P. 490.

7. ASPARAGUS (*Declinatus*) caule inermi ramis declinat-
tis foliis setaceis. Prod. Leyd. 29. *Asparagus with a*
smooth stalk, declining branches, and bristly leaves.
8. ASPARAGUS (*Asiaticus*) aculeis solitariis caule erecto
foliis fasciculatis, ramis filiformibus. Lin. Sp. Plant.
313. *Asparagus with single spines, an upright stalk, leaves*
growing in clusters, and very slender branches.
9. ASPARAGUS (*Capeensis*) spinis lateralibus terminalibus-
que, ramis aggregatis foliis fasciculatis. Lin. Sp.
Plant. 314. *Asparagus with spines growing on the sides*
and ends of the branches, which are in bunches, and leaves
coming out in clusters.
10. ASPARAGUS (*Sarmentosus*) foliis solitariis lineari lan-
ceolatis caule flexuoso aculeis recurvis. Flor. Zeyl.
124. *Asparagus with single, narrow, spear-shaped leaves,*
a flexible stalk, and recurved spines. *Asparagus acule-*
atus Zeylanicus maximus sarmentosus. H. L. 62.

The first sort is the common Asparagus, which is cultivated for the use of the table, and may have probably been brought by culture to the perfection it now is, from the wild sort, which grows naturally in the fens of Lincolnshire, where the shoots are no larger than straws; but if so, it must have been from very long culture and good management; for a friend of mine, who procured some seeds of the wild sort, which he cultivated with great care, in very rich ground, yet could not bring the roots to produce shoots more than half the size of the garden kind, which grew on the same ground; but he always found the wild sort came up a week or ten days earlier in the spring, and the shoots were exceeding sweet.

I have lately had some doubt, whether the sort of Asparagus which grows naturally in England, was the same with that mentioned by Casper Bauhin, because Tournefort and Vaillant both assert that they had cultivated that wild sort in the royal garden at Paris several years, and it had never altered, therefore I procured specimens of that, which I find to be extremely different from the English sort. The leaves are much finer and shorter, and are produced in much larger clusters; the branches grow much closer together, and the foot-stalks of the flowers are longer; therefore I believe it to be a distinct species from our wild sort, which appears to me undoubtedly the same as the Garden Asparagus.

The Garden Asparagus is propagated by seeds, in the procuring of which, there should be particular care to get it from a person of skill, who may be depended upon for his choice of the shoots, and integrity in supplying with his best seeds. But where a person is in possession of some good beds of Asparagus, it is much the best way to save it himself; in order to which, a sufficient number of the fairest buds should be marked early in the spring, and permitted to run up for seeds; because those which run up after the season for cutting the Asparagus is over, are generally so backward, as not to ripen the seeds unless the summer is warm, and the autumn very favourable. In the choice of the buds to be left for seeds, there must be great regard had to their size and roundness, never leaving any that are inclinable to be flat, or that soon grow open headed, always choosing the roundest, and such as have the closest tops. But as several of these produce only male flowers which are barren, a greater number of buds should be left, than might be necessary, if there could be a certainty of their being all fruitful. When the buds are left, it will be proper to thrust a stick down by each, but there must be care had in doing this, not to injure the crown of the root. These sticks will serve as marks to distinguish them from the others when they are all run up. Toward the end of September the berries will be fully ripe, when the stalks should be cut off, and the berries stripped into a tub, in which they may remain three weeks or a month to sweat, by which means the outer husks will be rotten; then fill the tub with water, and with your hands break all the husks by squeezing them between your

hands. These husks will all swim upon the water, but the seeds will sink to the bottom; so that by pouring off the water gently, the husks will be carried along with it, and by putting fresh water two or three times, and stirring your seed about, you will make it entirely clean: then spread the seed upon a mat or cloth, and expose it to the sun and air in dry weather, until it is perfectly dry, when it may be put into a bag, and hanged up in a dry place till the beginning of February, which is the proper season for sowing it; at which time you must prepare a bed of good rich earth made very level, whereon you must sow your seeds (but not too thick, which will cause the plants to be small;) then tread the bed all over to bury the seed in the ground, and rake it over smooth.

The following summer keep the ground diligently cleared from weeds, which will greatly add to the strength of the plants; and toward the latter end of October, when the haulm is quite withered, you may spread a little rotten dung over the surface of the ground, about two inches thick, which will preserve the young buds from being hurt with the frosts, &c.

The spring following the plants will be fit to plant out for good (for plants of more than one year's growth are unfit to remove, as I have often experienced; for young plants are much better than old, and will produce finer roots:) you must therefore prepare your ground by trenching it well, burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at least six inches below the surface of the ground; then level the whole plot very exactly, taking out all large stones: but this should not be done long before you intend to plant your Asparagus, in which you must be governed according to the nature of your soil or the season; for if your soil is dry and the season forward, you may plant early in March; but in a wet soil, it is better to wait till the end of that month, or the beginning of April, which is about the season that the plants are beginning to shoot. I know many people have advised the planting of Asparagus at Michaelmas, but this I have experienced to be very wrong; for in two different years I was obliged to transplant large quantities at that season, but I had better have thrown away the plants; for upon examination in the spring, I found most of the roots were grown mouldy, and decaying, and I am sure, not one in five of them succeeded, and those which did were so weak, as not to be worth their standing.

The season being come for planting, you must, with a narrow pronged dung-fork, carefully fork up the roots, shaking them out of the earth, and separating them from each other, observing to lay their heads even, for the more convenient planting them, which must be performed in this manner:

The plot of ground being levelled, you must begin at one side thereof, ranging a line very tight cross the piece, throwing out a trench exactly strait, by the line about six inches deep, being careful not to turn up the dung; into which trench you may lay your roots, spreading them with your fingers, and placing them upright against the back of the trench, that the buds may stand forward, and be about two inches below the surface of the ground, and at twelve inches distance from each other; then with a rake, draw the earth into the trench again, laying it very level, which will preserve the roots in their right position; then remove the line a foot farther back, and make another trench in the like manner, laying therein your plants as before directed, and continuing the same distance row from row, only observing between every four rows, to leave a distance of two feet four inches for an alley to go between the beds to cut the Asparagus, &c.

The plot of ground being finished and levelled, you may sow thereon a small crop of Onions, which will not hurt the Asparagus, provided the Onions are not too close, and tread in the seeds, raking the ground level.

There are some persons who plant the seeds of Asparagus in the place where the roots are to remain, which is a very good method, if it is performed with care. The way is this: after the ground has been well trenched and dunged, they lay it level, and draw a line cross the ground (in the same manner as is practised for planting of the young plants;) then with a dibble make holes at a foot distance, into each of which they drop two seeds, for fear one should miscarry; these holes should not be more than half an inch deep; then cover the seeds, by striking the earth in upon it, and go on removing the line a foot back for another row; and after four rows are finished, leave a space for an alley between the beds, if it is designed to stand for the natural season of cutting; but if it is to be taken up for hot-beds, there may be six rows planted in each bed, and the distance in the rows need not be more than nine inches. This should be performed by the middle of February, because the seeds lie long in the ground; but if Onions are intended to be sown upon the ground, that may be performed a fortnight or three weeks after, provided the ground is not stirred so deep as to disturb the Asparagus-seeds, in raking the Onion-seeds into the ground.

As the roots of Asparagus always send forth many long fibres which run deep into the ground, so when the seeds are sown where they are to remain, the roots will not be broken or injured, as those must be which are transplanted; therefore will shoot deeper into the ground, and make much greater progress, and the fibres will push out on every side, which will cause the crown of the root to be in the center; whereas in transplanting, the roots are made flat against the side of the trench.

When the Asparagus is come up, and the Onions have raised their seed-leaves upright (which will be in six weeks after planting) you must with a small hoe cut up all the weeds, and thin the crop of Onions where they may have come up in bunches: but this must be done carefully, and in dry weather, that the weeds may die as fast as they are cut up, being careful not to injure the young shoots of Asparagus, as also to cut up the Onions which grow near the shoots. This work must be repeated about three times, which, if well done, and the season not too wet, will keep the ground clear from weeds until the Onions are fit to be pulled up, which is commonly in August, and is known when their greens fall down and begin to wither. When you have drawn off the Onions, it will be necessary to clean the ground well from weeds, which will keep it clean till the alleys are dug to earth the beds, which must be done in October, when the haulm is decayed; for if you cut off the haulm while green, the roots will shoot fresh again, which will greatly weaken them. This young haulm should be cut off with a knife, leaving the stems two inches above ground, which will be a guide for you to distinguish the beds from the alleys; then with a hoe clear off the weeds into the alleys, and dig up the alleys, burying the weeds in the bottom, and throw the earth upon the beds, so that the beds may be about four or five inches above the level of the alleys: then a row of Coleworts may be planted in the middle of the alleys, but never sow or plant any thing upon the beds, which would greatly weaken the roots; nor would I ever advise the planting of Beans in the alleys, as is the practice of many; for that greatly damages the two outside rows of Asparagus. In this manner it must remain till spring, when some time in March, the beds should be hoed over, to destroy all young weeds; then rake them smooth, and observe all the succeeding summer to keep them clear from weeds, and in October dig up the alleys again, as was before directed, earthing the beds, &c.

The second spring after planting, some persons begin to cut some of the buds of Asparagus for use, though it would be much better to stay until the third year; therefore now the beds should be forked with a flat-pronged fork made on purpose, which is commonly

called an Asparagus-fork: this must be done before the buds begin to shoot in the spring, and should be performed with care, lest you fork too deep, and bruise the head of the root; then rake the beds over smooth, just before the buds appear above ground, which will destroy all young weeds, and keep your beds clean much longer than if left unraked, or if done so soon as forked. When the buds appear about four inches above ground, you may then cut them; but it should be done sparingly, only taking the large buds, and suffering the small to run up to strengthen the roots; for the more you cut, the greater will be the increase of buds, but they will be smaller and the roots sooner decay. In cutting the buds, you must open the ground with your knife (which should be very narrow-pointed, and long in the blade, and filed with teeth like a saw) to see whether any more young buds are coming up close by it, which might be either broken or bruised in cutting the other, then with the knife saw it off about two inches under ground. This may appear a very troublesome affair to people unacquainted with the practical part, but those who are employed in cutting Asparagus, will perform a great deal of this work in a short time; but care in doing it is absolutely necessary to be observed by all who cut Asparagus.

The manner of dressing the Asparagus-beds is every year the same as directed for the second, viz. keeping them clean from weeds in summer, digging the alleys in October, and forking the beds toward the end of March, &c. only observe every other year to lay some rotten dung (from a Melon or Cucumber-bed) all over the beds, burying some in the alleys also, at the time for digging them up. This will preserve the ground in heart to maintain the roots in vigour, and by this management, a plot of good Asparagus may be continued for ten or twelve years in cutting, and will produce good buds, especially if it is not cut too long each season; for when it is not left to run up pretty early in June, the roots will be greatly weakened, and the buds will be smaller: therefore, in those families where Asparagus is required late in the season, a few beds should be set apart for that purpose, which will be much better than to injure the whole plantation, by cutting it too long.

I cannot help taking notice of a common error that has long prevailed with many people, which is, that of not dunging the ground for Asparagus, believing that the dung communicates a strong rank taste to the Asparagus, which is a great mistake, for the sweetest Asparagus is that which grows upon the richest ground; for poor land occasions that rank taste so often complained of, the sweetness of Asparagus being occasioned by the quickness of its growth, which is always proportionable to the goodness of the ground, and the warmth of the seasons. In order to prove this, I planted two beds of Asparagus, upon ground which had dung laid a foot thick; and these beds were every year dunged extremely thick, and the Asparagus produced from these beds was much sweeter than any I could procure, though they were boiled together in the same water.

The quantity of ground necessary to be planted with Asparagus, to supply a small family, should be at least eight rods, less than that will not do; for if you cannot cut one hundred at a time, it will scarcely be worth while, for you must be obliged to keep it after it is cut two or three days, especially in cold seasons, to furnish enough for one mess; but for a larger family, sixteen rods of ground should be planted, which, if a good crop, will furnish two or three hundred each day in the height of the season.

But as there are several people who delight in having early Asparagus, which is become a very great trade in the kitchen-gardens near London, I shall give proper directions for the obtaining it any time in winter.

You must first be provided with a quantity of good roots (either of your own raising, or purchased from such

such gardeners as plant for sale,) such as have been two or three years planted out from the seed-bed; and having fixed upon the time you would willingly have your Asparagus fit to cut, about six weeks before, you should prepare a quantity of new stable horse-dung, which should be thrown in a heap for ten days or more, to ferment; mixing some sea-coal ashes with it; then it should be turned over into a heap, where it must lie another week, when it will be fit for use. Then dig out a trench in the ground where you intend to make the bed, the width of the frames that are designed to cover it, and the length in proportion to the quantity you intend to have (which if designed only to supply a small family, three or four lights at a time will be sufficient,) but for a larger family, six or eight lights will not be too much: then lay down your dung into the trench, working it very regularly, and beat it down very tight with a fork, laying it at least three feet in thickness or more, when the beds are made in December; then put your earth thereon about six inches thick, breaking the clods and laying it level; and at one end, begin laying your roots against a little ridge of earth, raised about four inches high: your roots must be laid as close as possible one to the other, in rows, with their buds standing upright; and between every row lay a small quantity of fine mould, observing to keep the crown of the roots exactly level. When you have finished laying your bed with roots, you must lay some stiff earth up to the roots, on the outsides of the bed, which are bare, to keep them from drying; and thrust two or three sharp-pointed sticks, about two feet long, down between the roots, in the middle of the bed, at a distance from each other. The use of these sticks is to inform you what temper of heat the bed is in, which you may find by drawing up the sticks, and feeling the lower part; and if, after the bed has been made a week, you find it doth not heat, you may lay a little straw or litter round the sides, and also upon the top, which will greatly help it; or if you find it very hot, so as to endanger scorching of the roots, it will be advisable to let it remain wholly uncovered, and to thrust a large stick into the dung, on each side of the bed, in two or three places, to make holes for the great steam of the bed to pass off, which in a short time will reduce the bed to a moderate heat.

After the bed has been made a fortnight, you must cover the crowns of the roots with fine earth, about two inches thick; and when the buds begin to appear above ground through that earth, you must again lay on a fresh quantity, about three inches thick; so that in the whole, it may be five inches above the crowns of the root, which will be sufficient.

Then you must make a band of straw (or long litter,) about four inches thick, which must be fastened round the sides of the bed, that the upper part may be level with the surface of the ground: this must be fastened with strait sticks about two feet long, sharpened at the points, to run into the bed; and upon this band you must set your frames, and put your glasses thereon; but if, after your bed hath been made three weeks, you find the heat decline, you must lay a good lining of fresh hot dung round the sides of the bed, which will add a fresh heat thereto; and in bad weather, as also every night, keep the glasses covered with mats and straw; but in the day time, let it be all taken off, especially whenever the sun appears; which, shining through the glasses, will give a good colour to the Asparagus.

A bed thus made, if it works kindly, will begin to produce buds for cutting, in about five or six weeks, and will hold about three weeks in cutting; which, if rightly planted with good roots, will produce, in that time, about three hundred buds in each light; so that where Asparagus is proposed to be continued until the season of the natural being produced, a fresh bed should be made every three weeks, until the beginning of March, from the time of the first bed being made; for if the last bed is made about a week

in March, it will last till the season of natural Asparagus; for the last beds will come a fortnight sooner to cut after making, than those made about Christmas; and the buds will be larger, and better coloured, as they will then enjoy a greater share of the sun.

Where this method of forcing early Asparagus is intended, there should be every year such a quantity planted, which you shall judge necessary (unless you intend to buy the roots from some other garden;) the quantity of roots necessary to plant one light, is commonly known by the measure of the ground where they grow; for where there is a good crop, and few roots are missing, one rod of ground will furnish enough for a light; but this calculation is made from the ground planted with roots, which are designed to be taken up after two or three years growth for forcing, in which there are six rows in a bed; at but ten inches distance, and the plants eight or nine inches asunder in the rows; but where there is a greater space between the rows, and fewer rows in a bed, then there must be a greater quantity of ground allotted for each light. Most of the kitchen-gardeners about London, take up their Asparagus roots after two years growth from planting; but where the land is not very good, it will be better to let it have three years growth, for if the roots are weak, the buds of Asparagus will be very small, so not worth the trouble of forcing. The best ground for planting Asparagus, to have large roots for hot-beds, is a moist rich soil; but for those that are to remain for a natural produce, a middling soil, neither too wet nor too dry, but a fresh sandy loam, when well dunged, is preferable to any other.

The second sort is mentioned to grow naturally in Wales, and also near Bristol: I have received seeds from the island of Portland, which have succeeded in the Chelsea garden, by which I am convinced it is a different species from the Garden Asparagus; and also from the wild sort which grows naturally at Gibraltar, and also near Montpellier, is different from both; Mr. Magnol, of Montpellier, was also of the opinion that it was a different species, for he says, the common wild Asparagus and this grew near each other in the neighbourhood of Montpellier, and the young shoots of the former were sweet, whereas those of the latter were bitter. The same has been confirmed to me by several gentlemen, who have resided many years at Gibraltar and Minorca, where the second sort grows naturally in plenty.

This sort is propagated by seeds in the same manner as the garden kind, but must have a warmer situation; and the roots should be well covered in winter, to prevent the frost from penetrating the ground, which will destroy it.

The third sort hath white, crooked, shrubby stalks, which rise four or five feet high, but have no spines on them; the leaves come out in clusters from the same point, like those of the Larch-tree; these are very short, and end in sharp prickles, so that they are troublesome to handle. This sort grows naturally in the South of France, Spain, and Portugal. It is propagated by seeds as the former sorts, but is too tender to live abroad in England, so the roots should be planted in pots, or near a south wall, and sheltered in winter.

The fourth sort grows with shrubby stalks three or four feet high, with very white bark, and are armed with thorns which are single, coming out just below each turf of leaves. These stalks continue several years, and put out many branches, garnished with narrow short leaves. These continue green all the winter, if the plants are screened from severe frost.

It is propagated by seeds as the former, which may be procured from the Mediterranean, where it grows naturally; some of the plants should be kept in pots, that they may be sheltered in winter, and the others may be planted in the full ground in a warm situation, and in hard frosts covered, otherwise it will not live abroad in this country.

The fifth sort grows naturally at the Cape of Good Hope. This hath very crooked irregular stalks, which are

ASP

are shrubby, and rise eight or ten feet high, putting out several weak side branches, garnished with long narrow leaves, coming out in clusters like those of the Larch-tree; under each of these clusters is placed a single sharp thorn. The stalks continue several years, and the leaves keep green all the winter. This is commonly propagated by parting the roots, because the plants rarely produce seeds in this country; the best time for this is in April. The roots must be planted in pots, and removed into the green-house in the autumn, for these plants will not live abroad in England.

The sixth sort grows naturally in Spain, Portugal, and Sicily, generally in rocky places. This sends up many weak irregular shoots, which have no leaves, but instead thereof, are armed with short stiff thorns, which come out four or five together from the same point, and spread from each other every way. The flowers are small, of an herbaceous colour; the berries are larger than those of the common sort, and are black when ripe. This is tender, so must be treated as the third sort.

The seventh sort grows naturally at the Cape of Good Hope. This sends up from the root several slender stalks, which put out weak branches, declining downward; these are closely garnished with bristly leaves, like those of Garden Asparagus, which continue green through the year. It hath not produced any seeds in England, so is only propagated by parting the roots, as the fifth sort, and the plants should be treated in the same manner.

The eighth sort grows naturally at the Cape of Good Hope; this sends up many weak shoots growing in clusters, which are armed with sharp spines, both on the side and ends of the shoots; the leaves come out in small clusters, which continue green all the year. This doth not produce seeds in England, so is propagated as the fifth sort, and requires the same treatment.

The tenth sort sends out from the root many weak climbing branches which rise five or six feet high, garnished with narrow spear-shaped leaves coming out single; the shoots are armed with short crooked spines, which render it very troublesome to handle the plants; for they are so closely set on, that it is difficult to touch the branches. This is propagated by parting the root; but the plants must be placed in a moderate stove, otherwise it will not thrive in this country. It grows naturally in the island of Ceylon.

These plants are preserved in the gardens of the curious, where they add to the variety; being not difficult to manage, where there is conveniency to house them in winter. They should have a place among other exotic plants.

ASPARAGUS SCANDENS. See MEDEOLA.

ASPEN-TREE. See POPULUS.

ASPERIFOLIUS plants [asperifolius, of asper, rough, and folium, Lat. a leaf] are such plants as are rough-leaved, having their leaves placed alternately, or without any certain order, on their stalks: the class of plants so denominated by Mr. Ray, have a monopetalous flower, cut or divided into five parts; after every flower there succeed commonly four seeds. Of this class are Bugloss, Borage, Comfrey, Hounds Tongue, &c.

ASPERUGO, small Wild Bugloss.

The CHARACTERS are,

The empalement is of one leaf, cut slightly at the top into five equal parts; the flower is of one leaf, having a short cylindrical tube, cut at the top into five small blunt parts, which are closed at their base: it hath five short stamina, crowned by oblong summits; in the center there are four compressed germen, supporting a short slender style, crowned by a blunt stigma. The germen afterward become four oblong seeds, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

We know but one SPECIES of this genus, which is, **ASPERUGO.** Flor. Lapp. 76. *Small Wild Bugloss, Great*

ASP

Goose Grass, or German Madwort. Buglossum sylvestre caulibus procumbentibus. C. B. P. 257.

This is an annual plant, which is found wild in some parts of England, as near Newmarket, at Boxley in Suffex, and in Holy Island. It is preserved in botanic gardens for variety, and may be easily propagated by seeds, which should be sown in autumn; for if the seeds are kept out of the ground till spring, they do not succeed so well. When the plants come up, they require no other culture but to keep them clear from weeds, and in May they will flower: in June their seeds will be perfected, which, if suffered to scatter, will grow again in autumn; so that when this plant is once brought into a garden, it will maintain itself, provided it be allowed a place.

ASPERULA, Woodroof.

This plant grows wild in shady woods in many parts of England, and flowers in April or May, and is sometimes used in medicine.

Dr. Linnæus has joined to this genus the Gallium album, Gallium montanum, and Rubia synanchica Saxatilis. C. B. But as these grow wild in England, and are rarely admitted into gardens, I shall pass them over with just mentioning them.

ASPHODELUS [Ἀσφόδελος, Gr. by Pliny it is called Hastula, or Baccillus Regius, because when it flowers, the stalk resembles a royal scepter.] King's Spear.

The CHARACTERS are,

The flower has no empalement; it is of one leaf, cut into six parts, which spread open; at the bottom is inserted a globular nectarium, having six valves; it hath six awl-shaped stamina, which are inserted in the valves of the nectarium, and are crowned by oblong summits, which are prostrate, and turn upward; between the nectarium is placed a globular germen, supporting an awl-shaped style, crowned by a club-like stigma: the empalement afterward becomes a fleshy globular seed-vessel, having three cells, which are filled with triangular seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, entitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. **ASPHODELUS (Luteus)** caule folioso, foliis triquetris fistulosis. Hort. Cliff. 127. *King's Spear with a leafy stalk, and triangular fistular leaves.* Asphodelus luteus & flore & radice. C. B. P. 28.
2. **ASPHODELUS (Ramosus)** caule nudo foliis ensiformibus carinatis lævibus. Lin. Mat. Med. 172. *King's Spear with a naked branching stalk, and smooth, sword-shaped, carinated leaves.* Asphodelus albus ramosus mas. C. B. P. 28.
3. **ASPHODELUS (Albus)** caule nudo simplici foliis lineari-ensiformibus. *King's Spear with a single naked stalk, and narrow sword-shaped leaves.* Asphodelus albus non ramosus. C. B. P. 28.
4. **ASPHODELUS (Fistulosus)** caule nudo foliis strictis subulatis striatis subfistulosis. Hort. Cliff. 83. *King's Spear with a naked stalk, fistular awl-shaped leaves, and an annual root.* Phalangium parvo flore ramosum foliis fistulosis annuum. H. L.

The first sort is the yellow Asphodel, which is directed for use in medicine; this hath roots composed of many thick, fleshy, yellow fibres, joined into a head at the top; from whence arise strong, round, single stalks, near three feet high, garnished their whole length with long triangular leaves, which are boat-shaped, of a sea-green colour; the upper part of the stalk is adorned half way with yellow star-shaped flowers, which begin opening from the bottom, and are followed by others above; so that on the same spike, there is often a succession of flowers for a month. It flowers in June, and the seeds ripen in autumn.

There is a variety of this with a larger flower, mentioned in the catalogue of the Royal Garden at Paris, by the title of Asphodelus spiralis luteus Italicus magno flore, the seeds of which I received from the garden at Pisa, some years ago; and the first year of the plants flowering in Chelsea garden, the flowers were larger, and the spikes longer than those of the

common

A S P

common sort; but in two years time, they were so like the common sort as not to be distinguished from it, as were also the young plants which were raised from the seed sowed at Chelsea, therefore it should be esteemed an accidental variety.

The second sort hath roots composed of many thick fleshy fibres; to each of which is fastened an oblong tuber, as large as small potatoes; the leaves are long and flexible, having acute edges; these grow in irregular clusters, from the crown of the root; between these come out the stalks, which rise more than three feet high, sending out several side branches, which are naked; the upper part of these are adorned with many white star-shaped flowers, consisting of one leaf cut into six parts, each having a purple line running lengthways on the outside of each segment. The flowers grow in long spikes, flowering gradually upward. They appear the beginning of June, and the seeds ripen in autumn.

The third sort hath roots like the second, but the leaves are longer and narrower; the stalks of this are single, never putting out any side branches; the flowers are of a purer white, and grow in longer spikes. This flowers at the same time with the former.

The fourth sort is an annual plant; the roots of this are composed of many fleshy yellow fibres, the leaves are spread out from the crown of the root, close to the ground, in a large cluster; they are convex on their under side, but plain above, and hollow like a pipe; the flower-stalks rise immediately from the root, and grow about two feet high, dividing into three or four branches upward, which are adorned with white starry flowers, with purple lines on the outside. These flower in July and August, and their seeds ripen in October, soon after which the Plants decay. It grows naturally in the south of France, Spain, and Italy.

The first sort grows naturally in many of the islands of the Archipelago, and also in Sicily. The second, third, and fourth sorts grow naturally in Portugal, Spain, and Italy; the third sort is not quite so hardy as either of the other, so in very severe frost is sometimes killed, unless the roots are covered in winter.

The yellow sort multiplies very fast by roots, and will soon overspread a large border, if suffered to remain unremoved, or the side roots are not taken off; but the other sorts are not so productive of shoots from their sides, and are much better kept within bounds.

The second and third sorts do not increase very fast by their roots, nor should they be often transplanted, for that will weaken them, so that their flower-stems will not rise so tall, or produce so many flowers, as when they are left undisturbed for some years; therefore the best way is to propagate these by seeds.

These three sorts of Asphodel are very pretty ornaments for a flower-garden, and, requiring very little trouble to cultivate them, are rendered more acceptable. They may be all propagated by seeds, which should be sown soon after they are ripe, on a warm border of light fresh earth: in the spring the plants will appear, when you should carefully clear them from weeds, and in dry weather they must be frequently watered: if this be duly observed, the plants will have acquired strength enough to be transplanted by the Michaelmas following; at which time you must prepare a bed of fresh earth in the flower nursery, into which you should plant the roots, at about six inches distance every way; observing to plant them so low, as that the top of the roots may be three or four inches under the surface of the bed; and some old tan, or dung, should be spread over the surface of the ground, to keep out the frost: in this bed they may remain one year, during which time they should be kept clear from weeds; by which time, the roots having acquired strength enough to produce flowers the following year, they should, in autumn, when their leaves are decayed, be carefully taken up, and transplanted into the flower-garden, observing to place them in the middle of the borders, amongst

A S T

other hardy kinds of flowers, where being properly intermixed, they will make an agreeable variety, and continue a long time in flower.

The fourth sort is an annual plant, so is only propagated by seeds; these should be sown in the autumn; when they will more certainly grow than if sown in the spring: when the plants are up, they will require no other trouble but to keep them clean from weeds, until they have put out four or five leaves, when they should be carefully removed to the places where they are to remain for good. If the seeds of this plant are permitted to scatter, the plants will come up without care, and those which are not removed, will be the strongest plants, and produce a greater number of flowers.

ASPLENIUM, or Ceterach [is so called from ἀσπλην, privative, and (πλῆν) the spleen, because good against diseases of the spleen.] Spleenwort or Miltwaste.

The CHARACTERS are,

The leaves are like those of the Polypody, but less, and pretty round, notched toward the side; downy on their under side, having a squamous dust, in which, by the help of a microscope, membranous capsules, or seed pods, lying close to one another, are perceived, every one furnished with a little round cord, which by its construction opening the fruit into two parts, pours forth certain very small seeds: the root is fibrous. This plant thrives in stony places, as in walls, &c.

This plant is of the Fern kind, and grows upon old moist shady walls in divers parts of England; but is never cultivated in gardens. There are several species of this plant in America, but they have not been introduced into England.

ASTER [ἄστυ, Gr. a Star; so called because the flower is radiated with little leaves after the manner of a star.] Starwort.

The CHARACTERS are,

It hath a compound flower, composed of several female and hermaphrodite florets, included in one common scaly empalement; the rays or border of the flower is composed of several female florets, whose upper parts are stretched out on one side like a tongue, and indented in three segments at the end; the hermaphrodite florets form the disk or middle; which are funnel-shaped, and divided at the top into five parts, spreading open, and have each five short slender stamina, crowned with cylindrical summits; in the bottom is placed a crowned germen, supporting a slender style, crowned by a bifid stigma; the germen afterward becomes an oblong seed, crowned with down: the female flowers have a germen supporting a slender style, crowned by two oblong stigma, which turn backward. These have no stamina, but in other respects are like the hermaphrodite flowers.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, from the same flower having female and hermaphrodite florets included in the same empalement.

The SPECIES are,

1. **ASTER** (*Alpinus*) foliis lanceolatis hirtis, radicalibus obtusis, caule simplicissimo unifloro. Lin. Sp. Plant. 872. *Starwort with hairy spear-shaped leaves, those at the root blunt, and a single stalk, having one flower.* Aster montanus cæruleus magno flore foliis oblongis. C. B. P. 267.
2. **ASTER** (*Amellus*) foliis lanceolatis obtusis scabris trinerviis integris, pedunculis nudiusculis corymbosis squamis calycinis obtusis. Lin. Sp. Plant. 873. *Starwort with rough, blunt, spear-shaped leaves, which are entire, having three veins, naked foot-stalks, flowers in a corymbus, and blunt scales to the empalement.* Aster atticus cæruleus vulgaris. C. B. P. 267. *vulgarly called Italian Starwort.*
3. **ASTER** (*Tripolium*) foliis lanceolatis integerrimis carnosius glabris ramis inæquatis, floribus corymbosis. Lin. Sp. Plant. 872. *Starwort with smooth, fleshy, spear-shaped leaves, which are entire, unequal branches, and flowers in a corymbus.* Aster maritimus Tripolium dictus. Raii Hist. 270.
4. **ASTER** (*Linifolius*) foliis linearibus acutis integerrimis, caule corymboso ramosissimo. Hort. Cliff. 408. *Star-*

- wort with narrow pointed leaves, which are entire, and a very branched stalk growing in a corymbus. Aster Tripolii flore angustissimo & tenuissimo folio. Mor. Hist. 3. 121.
5. ASTER (*Novæ Angliæ*) foliis lanceolatis alternis integerrimis semiamplexicaulibus, floribus terminalibus. Hort. Cliff. 408. *Starwort with entire spear-shaped leaves, growing alternate, and half embracing the stalks, which are terminated by flowers. After Novæ Angliæ altissimus hirsutus floribus amplis purpuro-violaceis. Par. bat. 98.*
6. ASTER (*Undulatus*) foliis cordatis amplexicaulibus undulatis subtus tomentosis, floribus racemosis adscendentibus. Hort. Cliff. 408. *Starwort with heart-spear-shaped waved leaves, woolly on their underside, and flowers growing in ascending spikes. After novæ Angliæ purpureus Virgæ aureæ facie & foliis undulatis. Par. bat. 96.*
7. ASTER (*Puniceus*) foliis semiamplexicaulibus lanceolatis serratis scabris, pedunculis alternis subunifloris calycibus discum superantibus. Hort. Cliff. 408. *Starwort with rough, sawed, spear-shaped leaves, half embracing the stalks, foot-stalks growing alternate, with a single flower on each foot-stalk, whose empalement is higher than the disk. After Americanus latifolius puniceis caulibus. H. L. 649.*
8. ASTER (*Miser*) floribus ovatis disco radiis longiore. Lin. Sp. Plant. 877. *Starwort with oval flowers, whose disk is longer than the rays. After ericoides Mellioti agræ umbone. Hort. Elth. 40.*
9. ASTER (*Novi Belgii*) foliis lanceolatis subserratis sessilibus caule paniculato ramulis unifloris solitariis calycibus squarrosis. Hort. Cliff. 408. *Starwort with spear-shaped jagged leaves, growing close to the stalk, which is loose and spiked, and branches having a single flower with a rough empalement. After Novæ Belgicæ latifolius umbellatus floribus dilutè violaceis. H. L. 66.*
10. ASTER (*Linariifolius*) foliis lanceolato-linearibus subcarnosis integerrimis planis floribus corymbosis fastigatis pedunculis foliolosis. Lin. Sp. Plant. 874. *Starwort with narrow, spear-shaped, fleshy leaves, which are plain and entire, flowers gathered into a corymbus, and leafy foot-stalks. After Tripolii flore. C. B. P. 267.*
11. ASTER (*Concolor*) caule simplicissimo foliis oblongo-ovatis sessilibus integerrimis racemo terminali. Flor. Virg. 178. *Starwort with single stalks, oval entire leaves growing close to the stalks, which end in a loose spike.*
12. ASTER (*Ericoides*) foliis linearibus integerrimis, caule paniculato, pedunculis racemosis, pedicellis foliosis. Flor. Virg. 124. *Starwort with linear leaves, a paniculated stalk with branching leafy foot-stalks. After ericoides dumosus. Hort. Elth. 40.*
13. ASTER (*Cordifolia*) foliis cordatis serratis petiolatis, caule paniculato. Hort. Cliff. 408. *Starwort with sawed heart-shaped leaves, having foot-stalks, and a loose spiked stalk. After latifolius autumnalis. Cornut. Canad. 64.*
14. ASTER (*Tenuifolius*) foliis sub linearibus integerrimis pedunculis foliosis. Lin. Sp. 1227. *Starwort with narrow spear-shaped entire leaves, and leafy foot-stalks. After Americanus Belvidere foliis floribus ex cæruleo albicantibus spicis prælongis. Pluk. Phyt. tab. 78. f. 5.*
15. ASTER (*Grandiflorus*) caule corymboso foliis lanceolatis reflexis, floribus solitariis, calycibus squarrosis. Flor. Leyd. 168. *Starwort with a corymbous stalk, spear-shaped, reflected leaves, and single flowers with rough empalements. After Virginianus pyramidatus Hyssopi folius asperis calycis squamulis foliaceis. Mart. Cent. 19.*
16. ASTER (*Scabris*) foliis lanceolatis scabris integris, caule ramoso, pedunculis foliosis, calycibus obtusis. *Starwort with rough spear-shaped entire leaves, and a branching stalk, with leafy foot-stalks. After Atticus Alpinus alter. C. B. P. 267.*
17. ASTER (*Glabris*) foliis oblongo-lanceolatis acutis serratis caule ramoso floribus terminalibus calycibus linearibus erectis. *Starwort with oblong, spear-shaped, pointed sawed leaves, and a branching stalk, terminated by flowers, whose empalements are very narrow, and erect.*

- After Persicæ foliis serratis glabris, floribus sparsis pallidè cæruleis. Dillen. Cat. Oxon.
18. ASTER (*Tradescanti*) foliis oblongis acutis basi latioribus semiamplexicaulibus, caule ramoso floribus terminalibus plerumque solitariis. *Starwort with oblong pointed leaves, broad at their base, half embracing the stalks, which are branched, and terminated with flowers, for the most part singly. After cæruleus ferotinus frutescens Tradescanti. Raii Hist. 269. commonly called Michaelmas Daisy.*
19. ASTER (*Præcox*) caule erecto hirsuto foliis oblongis acutis scabris acutè dentatis semiamplexicaulibus floribus corymbosis, calycibus hirsutis erectis. *Starwort with a hairy upright stalk, oblong pointed rough leaves, sharply indented, half embracing the stalks, and flowers in a corymbus with hairy erect empalements. After Pyrenaicus præcox flore cæruleo majori. H. R. Par.*
20. ASTER (*Altissimus*) caule altissimo hirsuto simplicissimo foliis oblongis acutis basi latioribus semiamplexicaulibus floribus tribus sessilibus terminalibus. *Starwort with a very tall, hairy, unbranched stalk, oblong pointed leaves, which are broader at the base, and half embrace the stalks, which are terminated by three flowers sitting very close.*
21. ASTER (*Ramocissimus*) caule ramocissimo patulo, foliis lineari-lanceolatis rigidis, floribus serratis positis pedunculis foliosis. *Starwort with a very branching spreading stalk, narrow, spear-shaped, stiff leaves, flowers placed one above another, and leafy foot-stalks.*
22. ASTER (*Umbellatus*) foliis lanceolatis acutis scabris, caule simplici floribus umbellatis terminalibus. *Starwort with rough pointed spear-shaped leaves, and a single stalk, terminated by flowers, growing in an umbel.*
23. ASTER (*Nervosus*) foliis nervosis lanceolatis acutis linearibus caule simplici floribus terminalibus quasi umbellatum dispositis. *Starwort with narrow, spear-shaped, pointed, nervous leaves, a single stalk, terminated by flowers growing almost in an umbel.*
24. ASTER (*Paniculatus*) foliis inferioribus ovatis basi semiamplexicaulibus, superioribus lanceolatis parvis caule paniculato ramis unifloris pedunculis foliosis. *Starwort with the lower leaves oval, whose base half embraces the stalks, the upper leaves small and spear-shaped, a stalk terminated by a loose spike, with a single flower on each branch, and a leafy foot-stalk.*
25. ASTER (*Rigidus*) floribus terminalibus solitariis foliis linearibus alternis. Flor. Virg. 98. *Starwort with single flowers at the ends of the branches, and very narrow leaves placed alternately.*
26. ASTER (*Latifolius*) foliis lineari-lanceolatis glabris trinerviis floribus corymbosis terminalibus. *Starwort with smooth spear-shaped leaves, with three veins, and flowers in a corymbus, which terminate the stalks. After latifolius Tripolii flore. H. R. Par.*
27. ASTER (*Dumosus*) foliis linearibus integerrimis caule paniculato. Hort. Cliff. 408. *Starwort with very narrow leaves, which are entire, and a loose spike of flowers. After Novæ Angliæ. linariæ foliis Chamæmeli flore. Par. Bat. Prod. 95.*
28. ASTER (*Annus*) foliis lanceolatis lateribus inferiorum crenatis, radice annuâ, caule corymboso pedunculis nudis. Hort. Cliff. 409. *Starwort with spear-shaped leaves, the sides of the lower leaves jagged, an annual root, and stalks ending with a corymbus of flowers, with naked foot-stalks. After ramosus annuus Canadensis. Mor. Hist.*
29. ASTER (*Fruticosus*) foliis linearibus fasciculatis punctatis, pedunculis unifloris nudis, caule fruticoso rugoso. Hort. Cliff. 409. *Starwort with narrow pointed leaves growing in clusters, naked foot-stalks with one flower, and a shrubby stalk. After Africanus frutescens foliis angustis & plerumque conjunctis. Hort. Amst. 2. p. 53.*
30. ASTER (*Chinensis*) foliis ovatis angulatis dentatis, petiolatis calycibus terminalibus patentibus foliosis. Hort. Cliff. 407. *Starwort with oval angular indented leaves, and the empalements terminated by spreading leaves. After Chenopodii folio annuus, flore ingenti specioso. Hort. Elth. 38.*

31. ASTER (*Aurantius*) foliis pinnatis. Hort. Cliff. 407. *Starwort with winged leaves.* After Americanus foliis pinnatis & ferratis floribus aurantis. Houft. MSS.
32. ASTER (*Procumbens*) foliis ovatis dentatis caule procumbente, pedunculis nudis axillaribus unifloris. *Starwort with oval indented leaves, a trailing stalk, and naked foot-stalks proceeding from the side with a single flower.* After Americanus procumbens bellidis minoris facie. Houft. MSS.
33. ASTER (*Mutabilis*) foliis lanceolatis ferratis, calycibus squarrosis, panicula subfastigiata. Lin. Sp. 1230. *Starwort with sawed spear-shaped leaves, rough flower-cups, and bundled panicles.* After Novi Belgii latifolius paniculatus, floribus saturate violaceis. H. L. 65.
34. ASTER (*Sibiricus*) foliis lanceolatis venosis scabris extimoferratis, caulibus striatis, pedunculis tomentosis. Lin. Sp. 1226. *Starwort with veined spear-shaped leaves, striated stalks, and woolly foot-stalks.*
35. ASTER (*Divaricatus*) ramis divaricatis, foliis ovatis serratis, floralibus integerrimis obtusiusculis amplexicaulibus. Flor. Virg. 123. *Starwort with forked branches, oval sawed leaves, those near the flowers are obtuse, entire, and embrace the stalk.* After Americanus latifolius albus, caule ad summum brachiato. Pluk. Alm. 56.

The first sort grows naturally upon the Alps, where it seldom rises more than nine inches high, and when transplanted into a garden, not above sixteen. It sends up single stalks from the root, which are thinly garnished with oblong leaves; at the top of each stalk is one large blue flower, somewhat like those of the Italian Starwort. This flowers in June; the root is perennial, but must be planted in a shady situation, and a moist soil. It is propagated by parting the roots, which should be done in autumn.

The second sort is the Italian Starwort, which was some years past more common in the gardens than at present; for since the great variety of American Starworts have been introduced into England, this sort hath not been so much cultivated, though it is by no means inferior to the best of them, and, in some respects, preferable to most of them; for it is not so subject to creep by the root, as many of the American sorts do, whereby they often become troublesome in small gardens, nor do the stalks require supporting as they do, for these seldom grow more than two feet high, and the stalks are generally strong, so are very rarely broken by the wind. These grow in large clusters from the root, and each of them branch at the top into eight or ten foot-stalks, each of which is terminated by a single large flower, having blue rays, with a yellow disk. It flowers in October, and, in mild seasons, will often continue till the middle of November, during which time they are very ornamental plants in a garden. This sort is propagated by parting the roots, the best time for this work is soon after they are out of flower, for those which are removed in the spring will not flower so strong the succeeding autumn. These roots should not be removed oftener than every third year, where they are expected to produce many flowers.

It grows naturally in the vallies of Italy, Sicily, and Narbonne, and is generally supposed to be the Amellus mentioned by Virgil in his fourth Georgick, to grow in the pastures; the leaves and stalks being rough and bitter, the cattle seldom browse upon it, so that whenever there are any of these roots in the fields, they send up a thick tuft of stalks, which, being left after the grass is eaten bare, these being full of flowers, make a fine appearance, and therefore might engage the poet's attention.

The third sort grows naturally in salt marshes, which are flowed by the tides, and is seldom admitted into gardens. It flowers in July and August.

The fourth sort is a native in North America, but has been many years in the English gardens. It sends up many strong shoots from the root every spring, which rise between two and three feet high, garnished with oblong leaves, placed alternately, and half embrace the stalk with their base; from the main stalks,

many side branches are put out, for near half their length, these are garnished with smaller leaves, which diminish in their size to the top, where there is a single flower, terminating the stalk, of a blue colour. This flowers in August and September; it is easily propagated by parting the roots, soon after the flowers are past, and will thrive in almost any soil or situation.

The fifth sort sends up many stalks from the root, which rise five feet high; garnished with spear-shaped leaves which are entire, and half embrace the stalks, which are terminated by large purple violet flowers, growing in a loose panicle: it flowers in August, and is very hardy, so may be planted in any soil or situation, and is propagated by parting the roots.

The sixth sort grows naturally in North America. This hath broad heart-shaped waved leaves at the bottom, the stalks rise between two and three feet high, which send out small side branches, upon which the flowers come out in loose spikes, which are of a very pale blue colour, inclining to white. This flowers in the same season as the former, and may be propagated in the same manner.

The seventh sort sends up several strong stalks, upward of two feet high, which are of a purple colour, garnished with spear-shaped smooth leaves, whose base embrace the stalks half round; the flowers grow upon single foot-stalks, forming a corymbus at the top, and are of a pale blue colour; these appear the latter end of September. This comes from North America, and may be propagated in the same way as the former.

The eighth sort rises with slender stalks, upward of three feet high; sending out many weak branches on every side, garnished with very small leaves; the flowers come out on short foot-stalks, on every side of the branches, these are small, with white rays and a yellow disk. They appear in November, and often continue part of December. This comes from the same country with the former, and may be propagated as is before directed for them.

The ninth sort rises near four feet high, having broad leaves at the bottom which diminish gradually to the top; the flowers are produced in a loose kind of umbel at the top of the stalks, which are of a pale blue colour; these appear the latter part of August. This is hardy, and may be propagated as the former.

The tenth sort grows naturally in the south of France and Italy; the stalks of this divide into a great number of branches, which divide again toward the top into several smaller, fully garnished with very narrow leaves their whole length; the flowers grow in large clusters at the top, forming a sort of corymbus; they are of a pale bluish colour, and appear the beginning of August. This is hardy, and may be propagated by parting the roots, as the former.

The eleventh sort rises four feet high, with a single stalk, and oval leaves growing close to the stalks, which are terminated by slender loose spikes of pale blue flowers, which appear about Michaelmas. This grows naturally in North America, and is propagated as the sorts above-mentioned.

The twelfth sort sends up slender stalks three feet high, which send out slender side branches most of their length, so as to form a thick bush; these are garnished with very narrow leaves their whole length, and are terminated by single flowers.

The thirteenth sort grows about two feet high, having slender stalks, garnished with oblong, pointed, heart-shaped leaves, which are sharply sawed on their edges; the upper part of the stalks is divided into several small branches, which are terminated by white flowers growing in loose panicles. This flowers in September, and may be propagated as the former.

The fourteenth sort sends up stalks five feet high, which put out many slender side branches, garnished with narrow spear-shaped leaves, and are terminated by spikes of small white flowers, which appear the end of October. This sort spreads greatly at the root, so is apt to over-run the borders.

The fifteenth sort hath narrow, oblong, hairy leaves at the bottom; the stalks rise three feet high, garnished with small, narrow, rough leaves, which turn backward; the stalks send out many side branches, each being terminated by a single large blue flower. This sort flowers the end of October, and continues most part of November, when it makes a fine appearance. It doth not multiply fast by its roots, but may be propagated in plenty, by cuttings made from the young shoots in May, which, if planted in a bed of light earth, and shaded from the sun, will take root, and flower the same year. It is commonly called by the gardeners Catesby's Starwort, from Mr. Catesby, who brought it from Virginia.

The sixteenth sort sends up several stalks a foot and a half high, garnished with rough spear-shaped leaves, sending out many side branches which diverge from the stalk every way; these are terminated for the most part by one large blue flower, somewhat like those of the Italian Starwort, but paler, and comes earlier to flower. It grows naturally on the Alps, and is propagated by parting the root.

The seventeenth sort rises to the height of five feet, with branching stalks, garnished with oblong spear-shaped leaves, which are sawed on their edges. Each of the side branches are divided at the top into several foot-stalks, which are terminated by large, pale, blue flowers, and are in beauty in October. This is propagated by parting the roots, as the sorts beforementioned. It grows naturally in North America.

The eighteenth sort was brought from Virginia many years ago, by Mr. John Tradescant, who was a great collector of rarities; and from his garden it was soon dispersed, and became common. It is generally known by the title of Michaelmas Daisy, from its flowering about old Michaelmas day. The stalks of this sort are numerous, and rise about three feet and a half high, being fully garnished with oblong leaves ending in a point, whose base half embrace the stalks. These shoot out many lateral branches, which are terminated by pretty large flowers, of a very pale bluish colour, tending to white. The roots of this multiply very fast, and the seeds often are blown about, so that it propagates so much as often to be troublesome; it will thrive in any situation.

The nineteenth sort sends up several strong hairy stalks, which rise a foot and a half high, having many oblong rough leaves ending in a point, whose base half embrace the stalks, which divide into many small branches at the top, forming a kind of corymbus, each being terminated by one large blue flower, having a very hairy empalement. This flowers the latter end of July. It grows naturally on the Alps, so is very hardy, but should have a moist soil and a shady situation. It is propagated by parting the roots.

The twentieth sort rises with strong hairy stalks, to the height of eight or nine feet, which are upright, unbranched, and garnished with oblong hairy leaves, ending in a point; their base half surrounds the stalks, which are for the most part terminated by three large purple flowers inclining to red, and sit close to the top of the stalk, surrounded by a few narrow leaves. This sort flowers in November. It came from Philadelphia, where it naturally grows, and is propagated by parting the roots; it delights in a moist soil.

The twenty-first sort hath slender purplish stalks, which rise about three feet high, sending out many side branches almost the whole length, which spread horizontally, garnished with narrow, small, spear-shaped leaves; the flowers are produced in a sort of loose spike, growing one above another on each side the stalk. These are small, of a pale purplish colour, and appear in November. It grows naturally in North America, and is easily propagated by parting the roots.

The twenty-second sort I received from Philadelphia, where it grows naturally. This sends up stiff chan-

nelled stalks about two feet high, garnished with rough spear-shaped leaves ending in a point, placed alternately on every side the stalks; the flowers are white, and grow in a sort of umbel at the top of the stalks. It flowers the end of September, and is propagated by parting the roots.

The twenty-third sort I received from Mr. Peter Collinson, F. R. S. who procured it from Pennsylvania. This hath much the appearance of the former sort, but the leaves are narrower, whiter on their under side, and have three longitudinal veins; the flowers are also larger and whiter. It grows about the same height, and flowers at the same time with the former.

The twenty-fourth sort rises four feet high, the bottom leaves are oval and half surround the stalk at their base; the upper leaves are small and spear-shaped; the stalks put out side branches toward the top, which grow erect, forming a loose spike, each being terminated by one large blue flower, with a leafy foot-stalk; this flowers about the end of October. It grows naturally in North America, and is propagated by parting the roots.

The twenty-fifth sort sends up from the root several slender stalks near three feet high, garnished by many very narrow leaves, and puts out side branches, each being terminated by one white flower. This grows naturally in Philadelphia; it flowers in November, and is easily propagated by parting the roots.

The twenty-sixth sort rises about a foot and a half high; the stalks are garnished with narrow, spear-shaped, smooth leaves: the end of the stalks are terminated by foot-stalks on every side, each having one pale blue flower. This grows naturally in Canada, and is propagated by parting the roots. It is titled *After Canadensis linariae folio*. Hort. R. Par.

The twenty-seventh sort grows about two feet high, with erect stalks, garnished with narrow spear-shaped leaves, which come out irregularly in clusters; from the upper part of the stalks, there are a few side branches produced; which are garnished with narrow leaves; the flowers are produced in a panicle, which are of a pale blue colour, and appear in September. This is propagated by parting the roots.

The twenty-eighth sort is an annual plant, which when once introduced into a garden, the seeds will scatter, and the plants come up without care. This sends up strait stalks about two feet high, which are terminated by white flowers growing in form of a corymbus. It flowers in August, and the seeds ripen in October, and grows naturally in North America.

The twenty-ninth sort grows naturally at the Cape of Good Hope. This rises with a woody stem about three feet high, sending out side branches which are ligneous, garnished with narrow leaves coming out in clusters from one point, like those of the Larch-tree; the flowers are produced from the side of the branches, upon long slender foot-stalks singly; these are of a pale blue colour, and appear the beginning of March; as this plant never produces seeds in Europe, it is only propagated by cuttings, which may be performed any time in summer. These should be planted in small pots filled with light earth, and plunged into an old hot-bed; where, if they are shaded from the sun, and gently watered, they will put out roots in six weeks, when they may be placed in the open air; and in about a month after they should be separated, each planted into a small pot filled with light sandy earth. In October these must be removed into the green-house, and placed where they may enjoy as much free air as possible, but be secured from frost or damps, either of which will destroy them; so that they are much easier preserved in a glass-case, where they will enjoy more light and air than in a green-house; but they must not be placed in a stove, for artificial heat will soon destroy the plants. This sort is at present but in few English gardens.

The thirtieth sort is a native of China, from whence the seeds were sent to France by the missionaries, where the plants were first raised in Europe. In the year 1731, I received seeds of this, from which I raised plants with red, and some with white flowers; and in 1736, I received seeds of the blue flower, but these were all single. They came by the title of La Reine Marguerette, or the Queen of Daisies, by which title the French still call it. In 1752, I received seeds of the double flowers both red and blue, and in 1753, the seeds of the double white sort, from my worthy friend Dr. Job Baister, F. R. S. of Zirkzee. These have retained their difference from that time without variation, yet as they are generally supposed to be only varieties, I have not inserted them as different species.

As these are annual plants, they are only propagated by seeds, which must be sown in the spring upon a gentle hot-bed, just to bring up the plants; for they should be inured to the open air as soon as possible, to prevent their being drawn up very weak: when the plants are big enough to remove, they should be carefully taken up and planted in a bed of rich earth at six inches distance each way, observing to shade them from the sun till they have taken new root; and if the season proves dry, they must be often refreshed with water. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flower-garden where they are designed to remain; the plants should be taken up carefully, with large balls of earth to their roots, and the ground dug up and well broken with the spade, where the holes are made to receive the plants: after they are planted, and the earth closed about their roots, there should be some water given them to settle the earth. This work should, if possible, be done when there is rain, for then the plants will soon take new root, after which time they will require no other care but to keep them clear from weeds.

In August these plants will flower, by which time if the ground is rich in which they are planted, they will be two feet high, and furnished with many side branches, each of which is terminated by a large radiated flower, some white, some red, and others blue. These are some of the greatest ornaments in the flower-garden in autumn, during their time of flowering. The seeds ripen the beginning of October, which should be gathered when it is perfectly dry; and in order to preserve the kinds with double flowers, those which grow upon the side branches, which are commonly fuller of leaves than the flowers on the main stem, should always be preserved for seeds.

The thirty-first sort was discovered by the late Dr. Houston in the year 1731, at La Vera Cruz in New Spain. This is an annual plant, which rises with an upright stalk about one foot high, garnished the whole length with winged leaves, each consisting of two or three pair of lobes, terminated by an odd one: each of these lobes are heart-shaped, and sawed on their edges; at the top of the stalk is produced one large Orange-coloured flower, having a single empalement, cut into many slender segments which end in points. After the flower is past, each floret is succeeded by an oblong angular seed, crowned with long down. This is propagated by seeds, which should be sown on a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot filled with rich earth, and plunged into the tan-bed, observing to shade them until they have taken new root, as also to refresh them with water, and in warm weather admit free air to the plants. When these pots are filled with their roots, the plants should be carefully shaken out; and after paring off the outside roots, put into larger pots, filled with light earth, and plunged into the hot-bed again, where they may remain to flower and perfect their seeds, for they will not thrive in the open air. This sort flowers in July, and the seeds ripen in September.

The thirty-second sort was discovered by the late Dr. William Houston, in the year 1729, growing in plenty in the sandy ground about Vera Cruz, in America, where he drew the figure, and made a description of the plant upon the spot; which he sent to England with the seeds, some of which grew in the Chelsea garden, and the plants flowered the following summer, but did not perfect their seeds.

It hath bushy fibrous roots, which creep in the ground, and send out many slender round stalks, which bend and incline to the ground. These are about four or five inches long, destitute of leaves, each sustaining one flower, in shape and size of those of the common Field Daisy, of a whitish purple colour; but the rays are narrower. The disk is composed of several florets, which are succeeded by small seeds crowned with a pappous down. The empalement which includes the flowers, is scaly.

As this plant is a native of a warm climate, it will not live in the open air in England; therefore the seeds must be sown in a hot-bed, and the plants will require a stove to maintain them through the winter.

The thirty-third sort is a native of North America. This hath upright stalks about three feet high, garnished with spear-shaped sawed leaves; the flowers are produced in bunchy panicles, having rough empalements. It flowers the end of August, and is propagated by parting the roots in autumn.

The thirty-fourth sort grows naturally in Siberia; the stalks are striated about two feet high, sending out side branches, garnished with rough, veined, spear-shaped leaves; the foot-stalks of the flowers are woolly, each supporting one large blue flower. This flowers in August, and is propagated by parting the roots in autumn.

The thirty-fifth sort sends up rough stalks about two feet high, dividing toward the top into many forked branches, diverging from each other, garnished below with oval sawed leaves; but the flowering stalks have entire obtuse leaves which embrace them with their base; the flowers are growing almost in an umbel; these appear the beginning of September. It is propagated by parting the roots as the former.

ASTERISCUS. See BUPHTHALMUM.

ASTEROIDES, Bastard Starwort. See INULA.

ASTRAGALOIDES. See PHACA.

ASTRAGALUS, Wild Liquorice, Liquorice Vetch, or Milk Vetch.

The CHARACTERS are,

It hath a butterfly flower, whose empalement is of one leaf, cut into five acute segments at the top. The standard (or vexillum) is upright, blunt, and reflexed on the sides; the wings are oblong, and shorter than the standard; the keel is the same length with the wings, and bordered.

It hath ten stamina, nine of which are joined, and one stands singly; these are crowned by roundish summits. At the bottom of the flower is situated a taper germen, supporting an awl-shaped style, crowned by a blunt stigma. The germen afterward becomes a pod having two cells, each having a row of kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnaeus's seventeenth class of plants, entitled Diadelphia Decandria, from the flower having ten stamina joined in two bodies.

The SPECIES are,

1. ASTRAGALUS (*Glycyphyllos*) caulescens prostratus leguminibus subtriquetis arcuatis foliis ovalibus pedunculo longioribus. Lin. Sp. Plant. 758. *Stalky prostrate Milk Vetch, with crooked pods almost triangular, and oval leaves longer than the foot-stalk.* Astragalus luteus perennis procumbens vulgaris sylvestris. Mor. Hist. 2. 107. *sometimes called Wild Liquorice.*
2. ASTRAGALUS (*Hamosis*) caulescens procumbens, leguminibus subulatis recurvatis glabris. Hort. Upsal. 226. *Stalky trailing Milk Vetch, with smooth awl-shaped pods bending inward.* Astragalus luteus annuus Monspeliacus procumbens. Mor. Hist. 2. 108.

3. **ASTRAGALUS** (*Alopecuroides*) caulescens, spicis cylindricis subsessilibus, calycibus leguminibusque lanatis. Lin. Sp. Plant. 755. *Stalky Milk Vetch with cylindrical spikes growing close to the stalks, and woolly pods and empalements.* Astragalus Alpinus procerior Alopecuroides. Tourn. Inst. 416.
4. **ASTRAGALUS** (*Cicer*) caulescens prostratus, leguminibus subglobosis inflatis mucronatis pilosis. Hort. Upsal. 226. *Milk Vetch with a prostrate stalk, and a globular, swelling, hairy pod, ending in a point.* Astragalus luteus perennis siliqua gemella rotunda vesicam referente. Mor. Hist. 2. 107.
5. **ASTRAGALUS** (*Epiglottis*) caulescens procumbens, leguminibus capitatis cordatis acutis reflexis complicatis. Lin. Sp. Plant. 759. *Milk Vetch with trailing stalks, and pods growing in beads, which are heart-shaped, pointed, reflexed, and complicated.* Astragalus Hispanicus siliqua epiglottidi simili flore purpureo major. H. L. 74.
6. **ASTRAGALUS** (*Montanus*) subcaulos scapis folio longioribus, floribus laxè spicatis erectis, leguminibus ovatis acumine inflexo. Prod. Leyd. 392. *Low Milk Vetch with flower-stalks longer than the leaves, and flowers growing in loose upright spikes.* Onobrychis floribus viciæ majoribus cæruleo-purpurascens sive foliis tragacanthæ. C. B. P. 351.
7. **ASTRAGALUS** (*Baticus*) caulescens procumbens, spicis pedunculatis, leguminibus prismaticis rectis triquetris apice uncinatis. Hort. Cliff. 225. *Milk Vetch with trailing stalks, spikes of flowers with foot-stalks, and upright triangular pods shaped like a prism pointed at the top.* Astragalus annuus maritimus procumbens latifolius floribus pediculo insidentibus. Tourn. Inst. 416.
8. **ASTRAGALUS** (*Arenarius*) subcaulescens procumbens floribus subracemosis erectis foliis tomentosis. Lin. Sp. Plant. 759. *Low trailing Milk Vetch with branching flowers growing erect, and woolly leaves.* Astragalus incanus parvus purpureus nostras. Pluk. Alm. 59.
9. **ASTRAGALUS** (*Physodes*) acaulos scapis folia æquantibus leguminibus inflatis subglobosis nudis. Lin. Sp. Plant. 760. *Low Milk Vetch with flower-stalks as long as the leaves, and naked, globular, swelling pods.* Astragalus acaulos leguminibus inflatis subglobosis. Amœnit. Acad.
10. **ASTRAGALUS** (*Christianus*) caulescens erectus floribus glomeratis subsessilibus ex omnibus axillis foliaceis. Lin. Sp. 755. *Milk Vetch with upright stalks, and glomerated flowers growing close to them, proceeding from all the wings of the leaves.* Astragalus Orientalis maximus incanus erectus, caule ab imo ad summum florido. Tourn. Cor. 29.
11. **ASTRAGALUS** (*Ægyptiacus*) caulescens scapis folio longioribus floribus laxè spicatis erectis, leguminibus arcuatis. *Stalky Milk Vetch with flower-stalks longer than the leaves, upright flowers growing in loose spikes, and arched pods.* Astragalus Ægyptius floribus spicatis purpurascens siliquis incurvis. Just.
12. **ASTRAGALUS** (*Sesameus*) caulescens diffusus capitulis subsessilibus lateralibus leguminibus erectis subulatis acumine reflexis. Hort. Cliff. 361. *Milk Vetch with diffused stalks, flower-heads growing close to the sides of the stalks, and awl-shaped upright pods reflexed at their points.* Astragalus annuus foliis & siliquis hirsutis plurimis in foliorum alis sessilibus. Pluk. Alm. 60.
13. **ASTRAGALUS** (*Galegiformis*) caulescens strictus glaber, floribus racemosis pendulis, leguminibus triquetris utrinque mucronatis. Lin. Sp. 1066. *Milk Vetch with smooth slender stalks, hanging branching flowers, and three-cornered pointed pods.* Astragalus Orientalis altissimus folio galegæ flore parvo flavescente. Tourn. Cor. 29.
14. **ASTRAGALUS** (*Uralensis*) acaulos scapo erecto foliis longiore leguminibus subulatis inflatis villosis erectis. Hort. Upsal. 226. *Low Milk Vetch, with upright foot-stalks to the flowers longer than the leaves, and awl-shaped, upright, swollen, hairy pods.* Astragalus non ramosus villosus & incanus spicatus floribus purpureo-violaceis. Amman. Ruth. 167. p. 126.
15. **ASTRAGALUS** (*Carolinianus*) caulescens erectus lævis pedunculis spicatis leguminibus ovato-cylindricis stylo acuminatis. Lin. Sp. Plant. 757. *Smooth, upright, stalky Milk Vetch, with spiked stalks, and oval cylindrical pods ending in sharp points.* Astragalus procerior non repens flore viridi flavescente. Hort. Elth. 45.
16. **ASTRAGALUS** (*Canadensis*) caulescens diffusus, leguminibus subcylindricis mucronatis foliolis subtus subvillosis. Lin. Sp. Plant. 757. *Milk Vetch with diffused stalks, pointed cylindrical pods, and the small leaves hairy on their under side.* Astragalus Canadensis flore viridi flavescente. Tourn. Inst. 416.
17. **ASTRAGALUS** (*Pilosus*) caulescens erectus pilosus floribus spicatis leguminibus subulatis pilosis. Lin. Sp. Plant. 756. *Milk Vetch with hairy upright stalks, flowers growing in spikes, and awl-shaped hairy pods.* Astragalus villosus erectus spicatus floribus flavescentibus. Amman. Ruth. 166.
18. **ASTRAGALUS** (*Procumbens*) incanus caulibus procumbentibus scapis folio æquantibus floribus glomeratis. *Hoary Milk Vetch with trailing stalks, foot-stalks equal with the leaves, and glomerated flowers.* Astragalus supinus siliquis villosis glomeratis. Tourn. Inst. R. H. 417.
19. **ASTRAGALUS** (*Incanus*) caulescens incanus, leguminibus subulatis recurvatis incanis. *Hoary stalky Milk Vetch, with awl-shaped recurved pods which are hoary.* Astragalus incanus siliqua recurva. Bot. Monsp.
20. **ASTRAGALUS** (*Capitatus*) caulescens capitulis globosis, pedunculis longissimis, foliolis emarginatis. Hort. Cliff. 360. *Stalky Milk Vetch with globular heads, very long foot-stalks, and the small leaves crenated at their points.* Astragalus Orientalis villosissimus capitulis rotundioribus floribus purpureis. Tourn. Cor. 29.
21. **ASTRAGALUS** (*Chinensis*) caulescens procumbens, capitulis pedunculatis, leguminibus prismaticis rectis triquetris apice subulatis. *Milk Vetch with trailing stalks, the foot-stalks terminated by flowers collected in beads, and three-cornered pods shaped like prisms.*
22. **ASTRAGALUS** (*Uncatus*) acaulis exscapus, leguminibus subulatis hamatis folio longioribus, foliolis obcordatis. Lin. Sp. 1072. *Milk Vetch without stalks, awl-shaped hooked pods longer than the leaves, and the small leaves almost heart-shaped.*

The first sort grows wild upon chalky ground in many parts of England, so is not often admitted into gardens. The root of this is perennial, but the stalks decay every autumn: it creeps at the root, so that it is too apt to spread where it is suffered to grow. It flowers in June, and the seeds ripen in September.

The second sort is annual; the branches of this trail upon the ground, which are striated; the leaves are winged, composed of about eight pair of lobes, terminated by an odd one; these are crenated at their points. The foot-stalks of the flowers arise from the wings of the leaves, which are about three inches long, garnished toward the top with a few pale yellow flowers rising one above another; these are succeeded by oblong pods, which bend in form of a sickle, being round on their outer side, but flattened on the opposite, ending in a point, opening in two cells, each having a row of square seeds. It flowers in June, and the seeds ripen in September. The seeds of this should be sown in April, in the place where they are to remain, and require no other care but to draw the plants out where they come up too thick, leaving them a foot and a half asunder, and keep them clean from weeds.

The third sort is a biennial plant, which grows naturally on the Alps. This rises with an upright hairy stalk near three feet high, garnished with long winged leaves, each having eighteen or twenty pair of oval lobes, terminated by an odd one. The flowers are produced in large cylindrical spikes from the wings of the leaves, sitting very close to the stalks, which are entirely covered with down, out of which the yellow flowers just peep; these are succeeded by oval pods

A S T

Pods shut up in the woolly empalements, having two cells, containing three or four square seeds in each. It flowers in June and July, and the seeds ripen in autumn, soon after which the plants decay. The seeds of this should be sown in April, on an open border, where the plants are designed to remain; and when the plants come up, they should be thinned, leaving them at least two feet asunder, and keep them clean from weeds; the second year they will flower, and produce seeds.

The fourth sort hath a perennial root, which sends out several striated stalks near three feet high, which, if not supported, prostrate themselves towards the earth. These are garnished with winged leaves placed alternately, at two inches distance, which are composed of about ten pair of oval small lobes, terminated by an odd one. The flowers arise from the wings of the leaves, upon foot-stalks two inches long, in small loose spikes, which are yellow, and shaped like the rest of this genus, and are succeeded by hairy, globular, swelling pods, ending with a sharp point, opening in two cells, in each of which are contained two or three hard reddish seeds. It flowers in July, and the seeds ripen in autumn. This grows naturally in the south of France and Italy. It is easily propagated by seeds, which should be sown upon an open border in the spring; and when the plants come up, they must be thinned and kept clean from weeds till autumn, when they should be transplanted to the place where they are to remain, and will afterward require no other culture, but to keep them clean from weeds. One or two of these plants in a garden by way of variety, may be admitted, but they have little beauty.

The fifth sort is annual. This sends out from the root two or three hairy trailing branches, which are garnished with winged leaves, composed of ten or twelve pair of blunt lobes, terminated by an odd one: the flowers come out from the wings of the leaves upon naked foot-stalks, four or five inches long, and are gathered into a round head; these are shaped like the others, but are pretty large, and of a deep purple colour, which are succeeded by short pods rough on their outsides; and when opened, are shaped like a heart, ending in a sharp point, containing three or four seeds.

The seeds of this should be sown on an open border in April, where the plants are to remain, and treated as the other annual sorts before-mentioned. It flowers in July, and the seeds ripen in autumn. It grows naturally in Spain and Portugal, from whence I have received the seeds.

The sixth sort is a perennial plant, which grows naturally upon the mountains in Spain, from whence I received it. This is a low plant, seldom rising with a stem more than three inches high, sending out winged leaves on every side, which are composed of many pairs of narrow lobes, set very close together on the midrib, terminated by an odd one. The flowers grow upon long foot-stalks, which rise above the leaves; these are large and of a purple colour, growing in a loose spike, and stand erect, and are succeeded by oblong crooked pods opening in two cells, filled with square seeds. It flowers in June, and the seeds ripen in August. This is propagated by seeds, which should be sown, and the plants treated in the same manner as the fourth sort, but should have a shady situation and a stronger soil.

The seventh sort is annual. This sends out several trailing branches near two feet long, which are garnished with winged leaves, composed of about ten pair of blunt lobes, set thinly on the midrib, terminated by an odd one: at the wing of each leaf comes out a foot-stalk near two inches long, sustaining four or five yellow flowers at the top, which are succeeded by triangular brown pods, shaped like a prism, growing erect, and open in two cells filled with greenish square seeds. It flowers in July, and the seeds ripen in autumn, soon after which the plants decay.

A S T

This may be treated in the same manner as the second.

The eighth sort is a perennial plant, which grows naturally upon hills in several parts of England, particularly in the North. This is a low plant, seldom rising more than two or three inches high, having many winged leaves composed of narrow woolly lobes, placed close on the midrib; the flowers are pretty large, of a purple colour, growing in loose spikes. It flowers in June, and the seeds ripen in August. This may be propagated as the fourth sort, and should have a shady situation.

The ninth sort hath a perennial creeping root, sending out leaves, which are composed of many pair of oval lobes, terminated by an odd one; the flower-stalks are as long as the leaves, which support a cylindrical spike of yellow flowers, which are succeeded by swollen pods, opening in two cells, containing several greenish seeds. This may be propagated as the fourth sort, and must have a shady situation. It flowers in June, and grows naturally in Siberia.

The tenth sort was discovered by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris, where they succeeded, from whence I was furnished with them. This sends up stalks near three feet high, which are large at bottom, and gradually diminish to the top; the leaves also at bottom are very long, and diminish upward, so as to form a sort of pyramid; these are winged, and composed of many large oval pair of lobes, which are placed thinly on the midrib, and terminated by an odd one; the flowers come out in clusters from the wings of each leaf, beginning near the root where the foot-stalks are the longest, and continuing upward, diminishing in their number. These are large, of a bright yellow colour, and are succeeded by cylindrical pods opening in two cells, filled with square yellow seeds. It flowers in July, and in very favourable seasons will perfect seeds in England. It is propagated by seeds, which should be sown, and the plants afterward treated as hath been directed for the fourth sort; with this difference only, to plant them in a warm border and a dry soil, otherwise the plants will not thrive well in this climate. The third year from seed the plants will flower, and continue many years in a proper soil.

The eleventh sort grows naturally in Egypt, from whence the seeds were sent to the royal garden at Paris, and Dr. Jussieu was so good as to send me part of the seeds: this is an annual plant, which rises with upright stalks a foot and a half high, thinly garnished with winged leaves, composed of about twelve pair of oval lobes, terminated by an odd one; the foot-stalks of the flowers arise from the wings of the leaves, and are extended beyond them; these are terminated by loose spikes of yellow flowers, which are succeeded by sickle-shaped pods. It flowers in July, and the seeds ripen in autumn, soon after which the plants decay. It may be propagated by seeds in the same manner as hath been before directed for the annual sorts, putting the seeds in a warm border and a dry soil, where the plants will perfect their seeds very well.

The twelfth sort grows naturally in Italy, and the south of France, from whence I received the seeds. This is an annual plant, which sends out several weak stalks without any order, garnished with winged leaves, composed of ten or twelve pair of lobes, and sometimes terminated by an odd one; these are hairy; at the foot-stalks of the leaves the flowers come out in small clusters, sitting close to the sides of the stalks, which are of a copper colour, and are succeeded by awl-shaped pointed pods growing erect, and reflected at their points. This is propagated by seeds in the same manner as the other annual sorts before mentioned; it flowers in July, and the seeds are ripe in autumn.

The thirteenth sort was discovered by Dr. Tournefort, in the Levant, who sent the seeds to the royal garden

A S T

at Paris, where they succeeded, and produced new seeds, so that many of the European gardens have been since supplied with it; this hath a perennial root, which sends out many upright stalks upward of five feet high, which are garnished with winged leaves, composed of about fourteen pair of oval lobes, terminated by an odd one; from the wings of the leaves the foot-stalks of the flowers arise, which are garnished with small yellow flowers, growing in loose spikes, and are extended beyond the leaves; these are succeeded by very short triangular pods, ending in a point, which open in two cells, filled with Ash-coloured square seeds. This flowers in June or July, and the seeds ripen in autumn. It is propagated by seeds, which may be sown in the spring, upon a border of light earth, and treated in the same manner as the fourth sort, till the following autumn, when the plants should be removed to an open situation and a dry soil, and when they have taken root, will require no farther culture. I have a root of this sort growing in the Chelsea garden, which is more than thirty years old, and produces plenty of seeds every year.

The fourteenth sort grows naturally upon the mountains in Germany; this never rises with a stalk, but sends out divers winged leaves from the root, which are composed of many blunt lobes, placed by pairs, and terminated by an odd one; the foot-stalks of the flowers arise immediately from the root, and are longer than the leaves, being terminated by spikes of blue flowers, which are succeeded by swelling awl-shaped pods, which are erect and hairy, having two cells which are filled with greenish seeds. It flowers in July, and the seeds ripen in autumn. The root is abiding, and the plant is propagated by seeds as the fourth sort, but should have an open situation.

The fifteenth sort grows naturally in Carolina, from whence I received the seeds; this hath a perennial root, but an annual stalk, which decays in autumn; from the root arise several upright stalks three feet high, garnished with winged leaves, composed of eighteen or twenty pair of oval smooth lobes, terminated by an odd one; from the wings of the leaves arise the foot-stalks, which are terminated by spikes of greenish yellow flowers, which are succeeded by oval cylindrical pods, to which adhere the style, which extends beyond the pods in a point. This flowers in August, but unless the season is warm, the plants seldom ripen their seeds in England. It is propagated by seeds, which should be sown upon a moderate hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a small pot filled with earth from the kitchen-garden, and plunged again into the hot-bed, to forward their making new roots; and when they are established in the pots, they must be inured to the open air, into which they should be removed the end of May, placing them in a sheltered situation, where they may remain till October, when they should be placed under a common frame to shelter them in winter; and in the spring they may be turned out of the pots, and planted in a warm border, where they will thrive and flower; and if the winter proves very severe, a little old tan should be laid over the roots, which will effectually preserve them.

The sixteenth sort grows naturally in most parts of North America; this hath a perennial root, which sends out many irregular stalks about two feet high, garnished with winged leaves, composed of many pair of oval lobes, hairy on their under side; from the wings of the leaves come out the foot-stalks, supporting spikes of greenish yellow flowers, which are succeeded by cylindrical pods, ending in a point. This flowers in July, and the seeds ripen the beginning of October. It is propagated by seeds, which should be managed as those of the fifteenth sort, but the plants are hardier, so will live thro' the winter in a common bed of light earth without covering.

The seventeenth sort rises with upright hairy stalks

A S T

two feet high, garnished with winged leaves, composed of many pair of oval woolly lobes, terminated by an odd one; from the wings of the leaves arise the foot-stalks, which are terminated by close spikes of yellow flowers; these are succeeded by hairy awl-shaped pods, having two cells, filled with brown seeds. This flowers in June, and the seeds ripen in autumn. It grows naturally in Siberia, from whence the seeds were sent to Dr. Amman, at Petersburg, who communicated them to me. It is a perennial plant, and propagated by seeds in the same manner as the fourth sort.

The eighteenth sort is a biennial plant: the seeds of this were sent me from Spain, where the plant grows naturally. This sends out many trailing stalks, which are divided into many smaller branches, garnished with many pair of narrow lobes, terminated by an odd one; the flowers are collected into heads, which terminate the foot-stalks, and are white; the foot-stalks are about the same length as the leaves; the pods are short and triangular, and the whole plant is covered with a silvery down. The seeds of this should be sown upon an open bed of light earth, where the plants are to remain, and the plants afterward treated in the manner directed for the annual sorts: the second year they will flower and perfect their seeds, after which they seldom continue.

The nineteenth sort grows upon the hills near Verona, from whence I received it. This sends up an upright stalk, seldom more than six inches high, garnished with small, winged, hoary leaves; the foot-stalks arise from the wings of the leaves, supporting three or four pale flowers, which are succeeded by sickle-shaped hoary pods. This is a biennial plant, and should be treated in the same manner as the last.

The twentieth sort was discovered by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris. This hath a perennial root, which sends up several erect stalks, garnished with winged leaves, composed of several pair of lobes, indented at the top; from the wings of the leaves come out long foot-stalks, supporting a globular head of purple flowers; these are rarely succeeded by pods in England. It flowers the end of July. It is propagated by seeds, which should be sown upon a moderate hot-bed in the spring, and the plants treated in the same manner as hath been directed for the fifteenth sort.

The twenty-first sort grows naturally in China: the plant is annual; the stalks spread on the surface of the ground, which are closely garnished with winged leaves, composed of eight or ten pair of oval smooth lobes, sitting close to the midrib; these are slightly indented at their end. The foot-stalks of the flowers are produced from the wings of the stalk, two of them generally arising at each place, and are equal to the leaves in length, supporting a globular head of purple flowers, which are succeeded by three-cornered pods growing erect in a compact head, opening in two cells, filled with small triangular seeds. This plant flowers in July and August, and the seeds ripen in autumn.

The seeds of this sort should be sown upon a hot-bed in March, and when the plants come up and are fit to transplant, they should be each put into a small pot filled with light earth, and plunged into another moderate hot-bed, being careful to shade them from the sun until they have taken new root; after which they should have free air admitted to them daily, proportional to the warmth of the season, and frequently but gently watered, with which management the plants will flower and produce seeds.

The twenty-second sort grows naturally about Aleppo, from whence the seeds were brought by Dr. Ruffel. The plant is annual, sending out a few branching stalks which trail upon the ground, garnished with narrow winged leaves, whose lobes are broader at their points than their base, and are indented so as

to become almost heart-shaped; the flowers are produced at the wings of the stalks in short loose spikes; they are almost white, and are succeeded by sickle-shaped pods, having two cells filled with square brown seeds. This flowers in July and August, and the seeds ripen in autumn.

This is propagated by seeds, which should be sown in the spring upon an open bed of light earth, and the plants treated afterward in the same manner as hath been directed for the annual sorts before-mentioned.

ASTRANTIA, Masterwort.

The CHARACTERS are,

It is a plant whose flowers grow in an umbel; the general umbel is composed of four or five small ones. The involucre of the general umbel is in one species composed of two large trifid leaves, and two entire. In another species of several small leaves: the involucre of the small umbel is composed of many small pointed leaves, which are longer than the umbels, coloured and spread open. The cupule of the flower is permanent, erect, and cut into five short acute segments; the flower is composed of five petals, which are erect, bifid, and bend inward: it hath five stamens the length of the petals, crowned by single summits; the oblong germen is situated below the receptacle, supporting two slender styles, crowned by spreading stigma; the germen afterward becomes an oval, blunt, channelled fruit, divided into two parts, having two oblong oval seeds inclosed in the cover.

This genus of plants is ranged in the second section of Linnæus's fifth class, entitled Pentandria Digynia, the flower having five stamens and two styles.

The SPECIES are,

1. ASTRANTIA (Major) foliis radicalibus quinquelobatis serratis, caulinis trilobatis acutis. Masterwort with the lower leaves divided into five sawed lobes, and those on the stalks cut into three acute lobes. *Astrantia major* coronâ floris purpurascens. Inst. R. H. 314.
2. ASTRANTIA (Candida) foliis quinquelobatis lobis tripartitis. Haller. Helv. 439. Masterwort with leaves having five tripartite lobes. *Astrantia major* coronâ floris candidâ. Tourn. Inst. 314.
3. ASTRANTIA (Minor) foliis digitatis serratis. Lin. Sp. Plant. 255. Masterwort with fingered leaves which are sawed. *Helleborus niger* faniculæ folio minor. C. B. P. 186.

The first sort hath many spreading leaves rising from the root, which are composed of five large lobes, sawed pretty deep on their edges; from between these the stalks arise near two feet high, having at each joint one leaf deeply cut into three sharp-pointed lobes; at the top of the stalk is produced the umbel of flowers, at the bottom of which is situated the general involucre, composed of two long trifid leaves, and two entire ones of the same length. The small umbels stand upon long foot-stalks or rays, under which is placed the involucre, composed of many spear-shaped pointed leaves, which extend beyond the rays, and are of a purplish colour.

The second sort hath much the appearance of the first, so has been supposed to be only a variety of it; but it differs from that in having five lobes to the leaves of the stalks, which are much shorter, and rounder at the point than those of the other. The general involucre of the umbel is composed of short narrow leaves, and those of the smaller umbels are shorter and white.

The third sort seldom rises a foot high; the foot-stalks of the leaves are four inches long; the leaves are divided into eight segments at the bottom, and spread out like a hand; these are deeply sawed on their edges; the involucre of the general umbel is composed of several very narrow leaves; the foot-stalks of the separate umbels are very large and slender, and toward the top often divide into three, each having a small umbel. The involucre of these small umbels are short and white.

These plants are very hardy; they may be propagated either by sowing their seeds, or parting their roots. If they are propagated from seeds, they should

be sown in autumn, soon after they are ripe; on a shady border; and, when the plants are come up, they should be carefully weeded, and where they are too close, some of the plants should be drawn out, to allow room for others to grow, until Michaelmas, when they should be transplanted where they are to remain; which should always be in a moist soil and a shady situation. The distance these plants should be placed, is three feet, for their roots will spread to a considerable width, if they are permitted to remain long in the same place. They require no other culture but to keep them clear from weeds, and every third or fourth year to be taken up at Michaelmas, and their roots parted and planted again. These plants are seldom preserved but in botanic gardens, there being no great beauty in their flowers. They all grow naturally upon the Alps.

ATHAMANTA, Lin. Gen. Plant. 301. Meum. Tourn. Inst. R. H. 312. Spiguel.

The CHARACTERS are,

It is a plant with an umbellated flower; the general umbel spreads open, and is composed of many small ones; the involucre of the great umbel is composed of many narrow leaves, which are shorter than the rays; those of the small ones are narrow, and equal with the rays: the flowers of the great umbel are uniform; those of the smaller have five inflexed heart-shaped petals, which are a little unequal; each flower hath five slender stamens, which are of the same length with the petals, and crowned by roundish summits; the germen is situated below the receptacle, supporting two reflexed styles, crowned by obtuse stigma; the germen afterward becomes an oblong channelled fruit, divided into two parts, each containing one oval channelled seed.

This genus of plants is ranged in the second section of Linnæus's fifth class of plants, entitled Pentandria Digynia, the flowers having five stamens and two styles.

The SPECIES are,

1. ATHAMANTA (Meum) foliolis capillaribus, seminibus glabris striatis. Hort. Cliff. 93. Spiguel with hair-like leaves, and smooth channelled seeds. *Meum* foliis Anethi. C. B. P. 148. commonly called Spiguel.
2. ATHAMANTA (Cretensis) foliolis linearibus planis hirsutis, petalis bipartitis, seminibus oblongis hirsutis. Lin. Mat. Med. 143. Spiguel with plain hairy leaves, petals divided into two parts, and oblong hairy seeds. *Daucus Creticus* foliis faniculi tenuissimis. C. B. P.
3. ATHAMANTA (Sicula) foliis inferioribus nitidis, umbellis primordialibus subseffilibus, seminibus pilosis. Hort. Upsal. 60. Spiguel with shining under leaves, the umbels at first sitting close, and hairy seeds. *Daucus secundus* foliis sophiæ folio. Zan. Hist. 80.
4. ATHAMANTA (Oreoselinum) foliolis divaricatis. Flor. Suec. 249. *Athamanta* with divaricated leaves. *Apium montanum* folio ampliore. C. B. P. 153.
5. ATHAMANTA (Cervaria) foliolis pinnatis decussatis, inciso-angulatis, seminibus nudis. Lin. Sp. 352. *Athamanta* with winged leaves, whose lobes are angularly cut, and naked seeds. *Daucus montanus* Apii folio major. C. B. P. 150.

The first sort is the common Spiguel used in medicine. This grows naturally in Westmoreland, and by the inhabitants there is called Bald-Money, or Bawd-Money; by some it is called Meum. This is a perennial plant; the stalks rise a foot and a half high, and are channelled; the leaves are very ramose, and composed of many fine hair-like leaves set pretty close, of a deep green; the stalk is terminated by an umbel of white flowers, which are succeeded by oblong smooth seeds.

This may be propagated by parting the roots at Michaelmas, or from seeds sown soon after they are ripe; the plants should have a shady situation and moist soil. It flowers in June, and the seeds ripen in August.

The second sort is the *Daucus Creticus*, of which there are two sorts, whose seeds are indifferently used in the shops, one of which is annual, but that here mentioned is a perennial plant, which sends out many

stalks, garnished with slender narrow leaves like those of Fennel, irregularly disposed. The flower-stalk rises about two feet high, sending out many branches, garnished the whole length with the same compound capillary leaves, and at the top are terminated by compound umbels, composed of near twenty small ones; these have white flowers with five petals, which are succeeded by oblong, hairy, channelled fruit, divided into two parts, each containing one oblong hairy seed.

This sort is propagated by seeds, which should be sown in autumn on an open bed of light dry ground; and when the plants come up in the spring, they should be kept clean from weeds, and thinned where they are too close, so that they may have room to grow till the following autumn, when they should be carefully taken up, and planted at about a foot distance in a bed of light sandy earth, where the roots will continue several years, and annually flower and produce ripe seeds. It flowers in June, and the seeds are ripe in September. This grows naturally in Candia, but is rarely injured by cold in this country.

The third sort is a perennial plant; this sends up from the root several upright stalks, near three feet high; which are terminated by compound umbels; these, at their first appearance, are very close and compact, but afterward spread open, and divide into several smaller umbels; the foot-stalks or rays of these are short and hairy. The flowers are composed of five white petals, which are not quite equal, and are succeeded by oblong woolly fruit, divided into two parts, each containing one oblong channelled seed.

This may be propagated in the same manner as the former, and is equally hardy; it grows naturally in Sicily, and some parts of Italy.

The fourth sort is a perennial plant, which grows naturally in some particular parts of England, France, and Germany; the leaves of this are linear, and acutely cut into oblong segments; the stalks rise two feet high, dividing toward the top into three or four branches, each being terminated by an umbel of white flowers, which are succeeded by oblong striated seeds. It flowers in July, and the seeds ripen in autumn.

The fifth sort grows naturally in the south of France, and in Austria: this hath a perennial root; the stalks rise three feet high, garnished with winged leaves, which are cut into angular segments; they are terminated by umbels of white flowers, which are succeeded by naked seeds. This flowers in July, and the seeds ripen in autumn.

These two sorts are seldom admitted into any gardens but those of botanists, for the sake of variety, being plants of little beauty or use. They are propagated by seeds, which should be sown in autumn soon after they are ripe, and the plants will appear the following spring, when they will require no other care but to thin them where they are too close, and keep them clean from weeds. The second summer they will flower and produce ripe seeds, but the roots will abide several years where they are desired.

ATHANASIA. Lin. Gen. 943. Baccharis. Vaill. Act. Gall. 1719. Goldyllocks.

The CHARACTERS are,

The envelope is imbricated, oval, and the scales are spear-shaped; the flower is of the compound kind; the florets are uniform and longer than the corolla; the hermaphrodite florets are funnel-shaped, cut into five segments, which are crest; they have each five short hair-like stamina, with cylindrical tubulose summits, and an oblong germen with a slender style, terminated by an obtuse bifid stigma; each floret has an oblong seed with a chaffy down between them.

This genus of plants is ranged in the first order of Linnæus's nineteenth class, entitled Syngenesia Polygamia Æqualis; the florets of this order are all hermaphrodite.

The SPECIES are,

1. **ATHANASIA** (*Dentata*) corymbis impositis, foliis in-

ferioribus linearibus dentatis, superioribus ovatis serratis. Lin. Sp. 1181. *Athanasia* with a compound corymbus, the lower leaves linear and indented, the upper oval and sawed. Coma aurea Africana frutescens, foliis inferioribus incis, superioribus dentatis. Com. Rar. Pl. 41.

2. **ATHANASIA** (*Trifurcata*) corymbis simplicibus, foliis trilobis cuneiformibus. Lin. Sp. 1181. *Athanasia* with a single corymbus, and wedge-shaped leaves with three lobes. Coma aurea Africana fruticans, foliis glaucis & in extremitate trifidis. Hort. Amst. 2. p. 97.

3. **ATHANASIA** (*Crithmifolia*) corymbis simplicibus, foliis semitrifidis linearibus. Lin. Sp. 1181. *Athanasia* with a simple corymbus, and linear semitrifid leaves. Coma aurea fruticans foliis angustissimis trifidis. Burm. Afr. 186.

4. **ATHANASIA** (*Pubescens*) corymbus simplicibus, foliis lanceolatis indivisis villosis. Amœn. Acad. 4. p. 329. *Athanasia* with a simple corymbus, and spear-shaped, undivided, hairy leaves. Coma aurea Africana fruticosa, omnium maxima, foliis tomentosis & incanis. Hort. Amst. 2. p. 93.

5. **ATHANASIA** (*Annua*) corymbus simplicibus coarctatis, foliis pinnatifidis dentatis. Lin. Sp. 1182. *Athanasia* with a simple corymbus, and winged indented leaves. Elichrysium inodorum glabrum, coronopi folio glabrum. Magn. Montp. 307.

6. **ATHANASIA** (*Maritima*) pedunculis unifloris subcorymbosis, foliis lanceolatis indivisis crenatis obtusis tomentosis. Lin. Sp. 1182. *Athanasia* with single flowers on each foot-stalk formed like a corymbus, and spear-shaped, obtuse, woolly leaves. Gnaphalium maritimum. C. B. P. 263.

The first sort grows naturally at the Cape of Good Hope: this hath a low, shrubby, branching stalk, which seldom rises three feet high; the branches are garnished with two sorts of leaves, those toward the bottom are linear and indented, but the upper are oval and sawed on their edges: the flowers are disposed in a compound corymbus at the end of the branches; they are of a pale yellow, and appear early in summer, and if the season proves favourable, will be succeeded by ripe seeds in autumn.

The second sort is a native of the Cape of Good Hope: this rises with a shrubby stalk five or six feet high, dividing into many irregular branches, garnished with flat glaucous leaves cut at their extremity into three segments; these have an agreeable odour when bruised. The flowers are produced in a simple corymbus at the extremity of the branches; they are of a bright yellow colour, and appear in August, but are seldom succeeded by ripe seeds in England.

The third sort grows naturally at the Cape of Good Hope: this hath a shrubby branching stalk like the former; the leaves are linear, and divided more than half their length, some into three, and others into five narrow segments: the flowers are produced at the extremity of the branches in a simple corymbus, like those of the former sort in shape and colour, of which there is a succession on the same plant great part of summer; but unless the season is warm, they are rarely succeeded by ripe seeds in England.

The fourth sort rises with a shrubby stalk six or seven feet high; the branches are garnished with hairy, spear-shaped, entire leaves; the flowers are yellow, and produced in a simple corymbus at the extremity of the branches, but are not succeeded by good seeds in England.

These four sorts are easily propagated by cuttings during the summer months. If these are planted either in pots or upon an old hot-bed, and closely covered with glasses, shading them in the heat of the day, and refreshing them with water when they require it, they will put out roots in five or six weeks; and in two months they may be taken up and planted in pots filled with light earth, and placed in a shady situation until they have taken new root; after which they should be removed to a sheltered situation, mixing them with other exotic plants, where they may remain till the middle or end of October, according as the season proves

proves favourable; then should be removed either into a green-house, or a glass case, where they may enjoy as much free air as possible, but secured from frost, with which management they will thrive and produce plenty of flowers; but where they are drawn weak in winter, they will not appear sightly.

The fifth sort is an annual plant, which grows naturally in Africa. This hath an herbaceous stalk about nine inches high, which divides toward the top into three or four branches, garnished with smooth leaves, divided into segments like those of Buckhorn Plantain; the flowers are large, of a bright yellow colour, and are produced at the extremity of the branches in a compact simple corymbus; these appear in July and August, but are rarely succeeded by ripe seeds in this country.

This is propagated by seeds when they can be obtained good, which should be sown on a moderate hot-bed the latter end of March; when the plants are come up they should have air in proportion to the warmth of the season admitted to them, to prevent their drawing up weak; and so soon as they are big enough to remove they should be transplanted on another gentle hot-bed, at three inches distance, observing to shade them until they have got fresh root; after which they must have air and water, and by the end of May, the plants will have acquired strength enough to be transplanted into the open air; when some may be planted in pots to place among other exotic plants in summer, and the others into warm borders, where they will flower all the autumn, but unless the season is very warm, they will not ripen seeds.

The sixth sort grows naturally on the sea coasts in the warm parts of Europe, and also in some parts of Wales, from whence I have received plants. The stalks trail on the ground, seldom growing more than seven or eight inches long, garnished closely with woolly leaves, which are spear-shaped, entire, and obtuse; the flowers are of a bright yellow, each produced on a single foot-stalk, forming a kind of corymbus; they appear in June and July, but rarely ripen seeds in the garden.

This may be propagated by planting slips or cuttings during the summer months, in the same way as the African sorts; some of the plants should be put into pots to be placed under a hot-bed frame in winter, the other may be planted in a warm border, where if the winter proves favourable they will live, but they rarely survive cold winters.

A T M O S P H E R E [of ἄμωρ, a vapour, and σφαῖρα, Gr. a sphere] is an appendage of the earth, which consists of a thin, fluid, elastic substance, called air, surrounding the terraqueous globe to a considerable height.

The whole mass, or assemblage of ambient air, is commonly understood to be the atmosphere.

But the more accurate writers restrain the term atmosphere to that part of the air which is next to the earth, which receives the vapours and exhalations, and which is terminated by the refraction of the light of the sun.

Those spaces that are higher, and beyond these, are called æther; and, being supposed to be possessed by a finer substance, are called the æthereal regions, tho' these, perhaps, are not destitute of air.

This atmosphere insinuates itself into all the vacuities of bodies, and by that means becomes the great spring of most of the mutations here below, as generation, corruption, dissolution of vegetables, &c. to the pressure of the atmosphere, plants owe their vegetation, as well as animals do their respiration, circulation, and nutrition.

A T R A C T Y L I S. Lin. Gen. Plant. 837. Distaff Thistle.

The CHARACTERS are,

It hath a radiated compound flower, composed of many hermaphrodite florets, which are included in a common scaly unarmed empalement. This hath a permanent involucre, composed of several narrow plain leaves, which have sharp spines on their sides. The hermaphrodite florets

which compose the rays, or border, are stretched out on one side like a tongue, and are slightly indented in five parts. Those which compose the disk, or middle, are funnel-shaped, cut at the top into five parts; these have both five slender stamina in each, which are short, and crowned by cylindrical summits; in those of the disk is situated a short crowned germen, supporting a slender style, crowned by a bifid stigma. The germen afterward becomes a turbinated compressed seed, crowned with a plume of down, shut up in the empalement.

This genus of plants is ranged in the first section of Linnæus's seventeenth class, entitled Syngenesia Polygamia Æqualis, from the florets of the border and disk being hermaphrodite.

The SPECIES are,

1. **A T R A C T Y L I S** (*Cancellata*) involucris cancellatis ventricosis, linearibus dentatis calycibus ovatis, floribus flosculosis. Lin. Sp. Plant. 830. *Distaff Thistle with a bellied netted involucre, an oval, indented, linear empalement, and floscious flowers.* Cnicus exiguus capite cancellato semine tomentoso. Tourn. Inst. R. H.
2. **A T R A C T Y L I S** (*Humilis*) foliis dentato-sinuatis, flore radiato obvallato involucre patente, caule herbaceo. Lin. Sp. Plant. 829. *Distaff Thistle with sinuated indented leaves, a radiated flower strongly guarded by its spreading involucre, and an herbaceous stalk.* Cnicus aculeatus purpureus humilior. Tourn. Inst. R. H. 451.
3. **A T R A C T Y L I S** (*Gummifera*) flore acaule. Lin. Sp. Plant. 829. *Distaff Thistle with a flower without a stalk.* Cnicus Carlinæ folio acaulos gummifer aculeatus. Tourn. Cor. 33.

The first sort grows naturally in Spain, Sicily, and other warm parts of Europe. This is an annual plant which seldom rises more than eight or nine inches high, with a slender stem, thinly garnished with narrow hoary leaves, having spines on their edges; at the top of the stalk there are two or three slender branches sent out, each being terminated by a head of flowers, like those of the Thistle, with an involucre composed of several narrow leaves, armed with spines on their side, which are longer than the head of flowers. The empalement is curiously netted over, and is narrow at the top, but swelling below, containing many florets of a purplish colour. These are each succeeded by a single downy seed; it flowers in July, and, if the season be warm and dry, it will ripen its seeds in September, but in cold years never perfects seeds here.

It is propagated by seeds, which must be sown upon an open bed of light earth, where the plants are to remain, and will require no other care but to keep them clean from weeds, and thin the plants where they come up too close together.

The second sort rises with a stalk near a foot high, which is garnished with indented leaves, having small spines on their edges; the upper part of the stalk is divided into two or three slender branches, each supporting a head of purple flowers, having rays in the border, and florets in the disk, inclosed in a scaly empalement. The roots of this will live two or three years; it flowers in June, but unless the summer is warm and dry, it will not perfect seeds in England. The seeds of this sort should be sown where they are to remain, and will require no other culture than the former. It grows naturally about Madrid, from whence I received the seeds.

The third sort grows naturally in Italy, and the islands of the Archipelago, and is what the College of Physicians have placed among the medicinal simples, by the title of Carline Thistle; the root of this is perennial, and sends out many narrow leaves, which are deeply sinuated, and armed with spines on their edges. These lie close on the ground, and between them the flower is situated, without stalk, having many florets, inclosed in a prickly empalement. Those on the border are white, but those which compose the disk are of a yellowish colour. It flowers in July, but never perfects seeds in England.

It is propagated by seeds, which must be obtained from the countries where it grows naturally; these should be sown upon a border of light earth, in a warm situation, early in April, and when the plants come up, and are fit to transplant, they should be thinned, and those which are drawn out may be transplanted, leaving the other two feet asunder; after which the only culture they require is, to keep them clean from weeds in summer, and in winter to cover the roots with some old tanners bark, to prevent the frost from penetrating the ground.

The fourth sort grows naturally at the Cape of Good Hope; this rises with a shrubby stalk near three feet high, garnished with oblong leaves, indented on their edges, which have weak spines at each indenture; there are several weak branches sent out on the sides, each of which are terminated by a single head of flowers, inclosed in a common empalement, which spreads open, and are of a golden colour, but are never succeeded by seeds in England. This is propagated by slips, taken from the flower-stalks in June, and planted in pots filled with light earth, and plunged into an old bed of tanners bark, where the heat is gone, and shaded with mats in the heat of the day, until they have taken root; after which time they may be exposed in the open air till October, when they must be removed into shelter, and, during the winter, should have little water, and in summer exposed with other hardy exotic plants in a sheltered situation.

ATRAPHAXIS. Lin. Gen. Plant. 405. We have no English name for this.

The CHARACTERS are,

The flower hath a permanent empalement, composed of two small coloured leaves placed opposite. The flower hath two roundish sinuated petals larger than the empalement, which are permanent; it hath six capillary stamina, which are the length of the empalement, crowned with roundish summits; in the center is situated a compressed germen, having no style, but crowned by two stigma; the germen afterward becomes a roundish compressed seed, shut up in the empalement.

This genus of plants is ranged in the second section of Linnæus's sixth class, entitled Hexandria Digynia, the flower having six stamina and two stigma.

The SPECIES are,

1. **ATRAPHAXIS ramis spinosis.** Hort. Cliff. 138. *Atraphaxis with prickly branches.* Atriplex orientalis frutex aculeatus flore pulchro. Tourn. Cor. 38.
2. **ATRAPHAXIS inerimis.** Lin. Sp. Plant. 333. *Atraphaxis without spines.* Arbuscula Africana repens folio ad lateræ crispo, ad Polygona relata. Hort. Elth. 36.

The first sort grows naturally in Media, from whence Dr. Tournefort sent the seeds to the royal garden at Paris.

This is a shrub which rises four or five feet high, sending out many weak lateral branches, which are armed with spines, and garnished with small, spear-shaped, smooth leaves, of an Ash-colour. The flowers come out at the ends of the shoots in clusters, each consisting of two white leaves tinged with purple; and are included in a two leaved empalement, of a white herbaceous colour; these appear in August, but the seeds never ripen here, so the plant is propagated by cuttings, and must be screened from hard frost, which commonly destroys those which are planted in the open air.

The second sort sends out many slender branches, which trail on the ground when they are not supported, garnished with small oval leaves, about the size of those of the Knot Grass, waved and curled on their edges, embracing the stalk half round at their base, and are placed alternate. The flowers come out from the wings of the leaves, and have much the appearance of an apetalous flower, being composed of four herbaceous leaves, two of which are the empalement, the other two the petals; in the center is situated the compressed germen, attended by six stamina, but the seeds are never produced in

this country: It flowers in June and July. This is a native of the country about the Cape of Good Hope, from whence it was brought into the gardens in Holland, and has been several years in the English gardens, where it is allowed a place more for the sake of variety, than its beauty. It may be easily propagated by cuttings any time in the summer, and in winter the plants must be screened from frost.

ATRIplex, Orach, or Arach.

The CHARACTERS are,

It hath female and hermaphrodite flowers on the same plant. The hermaphrodite flowers have a permanent empalement of five oval concave leaves, with membranaceous borders; they have no petals, but five awl-shaped stamina, placed opposite to the leaves of the empalement, supporting double summits. In the center is placed the orbicular germen, with a short bipartite style, crowned with a reflexed stigma. The germen afterward becomes an orbicular compressed seed, shut up in the five-cornered empalement. The female flowers have a two-leaved empalement, which are large, plain, erect, and pointed. They have no petals nor stamina, but in the center a compressed germen, supporting a bipartite style, crowned by a reflexed stigma. The germen afterward becomes an orbicular compressed seed, inclosed in the heart-shaped valves of the empalement.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, entitled Polygamia Monœcia, the same plants having female and hermaphrodite flowers.

The SPECIES are,

1. **ATRIplex caule erecto herbaceo foliis triangularibus.** Hort. Cliff. 469. *Orach with an upright herbaceous stalk, and triangular leaves.* Atriplex hortensis alba live pallide virens. C. B. P. 119.
2. **ATRIplex caule fruticoso foliis deltoidibus integris.** Hort. Cliff. 469. *Orach with a shrubby stalk and entire leaves, shaped like the Greek delta.* Atriplex latifolia live Halimus fruticosus. Mor. Hist. p. 2. 207. commonly called Sea Purslane-tree.
3. **ATRIplex caule fruticoso foliis obovatis.** Flor. Succ. 829. *Orach with a shrubby stalk and oval leaves.* Atriplex maritima fruticosa, Halimus & Portulaca marina dicta angustifolia. Raii Syn.

There are several other species of this genus, some of which grow naturally in England, but as they are plants of no beauty, they are rarely admitted into gardens, for which reason I shall not enumerate them here.

The first of these plants was formerly cultivated in the kitchen-gardens as a culinary herb, being used as Spinage, and is now, by some persons, preferred to it; though, in general, it is not esteemed amongst the English; but the French, at present, cultivate this plant for use.

There are three or four different sorts of this, whose difference is only in the colour of the plants; one of which is of a deep green, another of a dark purple, and a third with green leaves and purple borders. These are supposed to be only accidental varieties which have come from the same seeds, but in forty years which I have cultivated these sorts, I have never yet observed them to vary. But as there is no other essential difference, I have not enumerated them here.

These plants are annual, so must be sown for use early in the spring, or at Michaelmas, soon after the seeds are ripe; at which time it generally succeeds better than when it is sown in the spring, and will be fit for use at least a month earlier. These plants require no other culture, but to hoe them when they are about an inch high; to cut them down where they are too thick, leaving them about four inches asunder, and to cut down all the weeds. This must be done in dry weather, otherwise the weeds will take root again, and render the work of little or no use. When the plants are grown about four inches high, it will be proper to hoe them a second time, in order to clear them from weeds; and, if you observe the plants are left too close in any part, they should then be cut out. If this be well performed, and in dry weather,

A T R

weather, the ground will remain clean until the plant is fit for use. Where these plants are sown on a rich soil, and allowed a good distance, the leaves will be very large, in which the goodness of the herb consists. This must be eaten while it is young; for, when the stalks become tough, it is good for nothing. Some few plants of each kind may be permitted to stand for seed, to preserve their kinds, which will ripen in August, and may then be cut, and laid on a cloth to dry; after which the seeds may be beaten out, and put up for use. The first sort is ordered by the College of Physicians for medicinal use.

The second sort was formerly cultivated in gardens as a shrub; and, by some persons, they were formed into hedges, and constantly sheared, to keep them thick; but this plant is by no means fit for such purposes, on many accounts, for it grows too vigorous; the shoots, in one month, at the growing season of the year, will be two feet long, provided they have a good soil; so that a hedge of this plant cannot be kept in tolerable order, nor will it ever form a thick hedge. But a worse inconvenience attends this plant; for, in very hard winters, it is often destroyed; as also, in very dry summers, many of the plants will decay, whereby there will become large gaps in the hedge.

But although this plant will not be proper for hedges, yet it may have a place in wilderness quarters, where it will serve to thicken; and the silver-coloured leaves will add to the variety, among other shrubs of the same growth. This will grow eight or ten feet high, and, if suffered to grow wild, without pruning, will spread several feet in compass, and will sometimes produce flowers.

It may be propagated by cuttings, which may be planted in any of the summer months, on a shady border; where, if they are duly watered, they will soon take root, and be fit to transplant the Michaelmas following, when they should be planted where they are to remain; for they do not succeed well in transplanting, especially when they are grown pretty large and woody.

The third sort grows wild in divers parts of England, on the sea side, from whence the plants may be procured; or it may be propagated by cuttings, in the same manner as the former sort. This is a low under shrub, seldom rising above two feet and a half, or at most three feet high, but becomes very bushy. The leaves of this kind are narrow, and of a whitish colour, but are not so white as those of the former. This may have a place amongst other low shrubs; and, if planted on a poor gravelly soil, will abide several years, and make a pretty diversity.

A T R O P A. Lin Gen. Plant. 222. Belladonna. Tourn. Inst. R. H. 77. Deadly Nightshade.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five parts; it is bell-shaped, the tube is short, and swells toward the brim, where it spreads open, and is divided into five equal parts. It hath five awl-shaped stamina rising from the base of the petal where they join, but at the top spread from each other, and are crowned with large summits which stand upward. In the center is situated an oval germen, supporting a slender style, which is crowned by an oblong transverse stigma. The germen afterward becomes a globular berry having three cells, sitting on the empalement, and filled with kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. A T R O P A (*Belladonna*) caule herbaceo, foliis ovatis integris. Lin. Sp. Plant. 181. *Deadly Nightshade with an herbaceous stalk, and oval entire leaves.* Belladonna majoribus foliis & floribus. Tourn. Inst. R. H. 77.
2. A T R O P A (*Frutescens*) caule fruticoso pedunculis confertis, foliis cordato-ovatis obtusis. Lin. Sp. Plant. 182. *Deadly Nightshade with a shrubby stalk, foot-stalks in clusters, and oval, heart-shaped, obtuse leaves.* Bel-

A T R

ladonna frutescens rotundifolia Hispanica. Tourn. Inst. R. H. 77.

3. A T R O P A (*Herbacea*) caule herbaceo, foliis ovatis nervosis marginibus undulatis. *Deadly Nightshade with an herbaceous stalk, and oval veined leaves waved on their edges.*

The first sort grows wild in many parts of England, but is not very frequent near London. I have observed it in Woodstock Park in Oxfordshire, and in great abundance in Uppark in Hampshire. This plant hath a perennial root, which sends out strong herbaceous stalks of a purplish colour, which rise to the height of four or five feet, garnished with oblong entire leaves, which toward autumn change to a purplish colour; the flowers are large and come out between the leaves singly, upon long foot-stalks; bell-shaped, and of a dusky brown colour on their outside, but are purple within. After the flower is past, the germen turns to a large round berry, a little flattened at the top, and is first green, but when ripe turns to a shining black, sitting close upon the empalement, and contains a purple juice of a nauseous sweet taste, and full of small kidney-shaped seeds. In some places this plant is called Dwale, but in general Deadly Nightshade, from its quality. It is rarely admitted into gardens, nor indeed should it be suffered to grow in any places where children resort, for it is a strong poison: there have been several instances within a few years past, of its deadly quality, by several children being killed with eating the berries, which are of a fine black colour, and about the size of a black Cherry, and not unpleasant to the taste.

Mr. Ray gives a good account of the various symptoms it produces, by what happened to a Mendicant Frier, upon his drinking a glass of Mallow wine, in which this plant was infused: in a short time he became delirious, soon after was seized with a grinning laughter, after that several irregular motions, and at last a real madness succeeded; and such a stupidity as those that are sottishly drunk have, which after all, was cured by a draught of vinegar.

There is also an instance of the direful effects of this plant recorded in Buchanan's History of Scotland, wherein he gives an account of the destruction of the army of Sweno, when he invaded Scotland, by mixing a quantity of the juice of these berries with the drink which the Scots by their truce were to supply them with; which so intoxicated the Danes, that the Scots fell upon them in their sleep, and killed the greatest part of them, so that there were scarcely men enough left to carry off their king.

The second rises with a shrubby stem to the height of six or eight feet, and divides into many branches, garnished with round leaves, in shape like those of the Storax-tree; these are placed alternately on the branches. The flowers come out between the leaves upon short foot-stalks, which are shaped like those of the former, but much less, of a dirty yellowish colour, with a few brown stripes; these are never succeeded by berries in England. It grows naturally in Spain, from whence the seeds may be procured. It is propagated by seeds, which should be sown in the spring upon a very moderate hot-bed, just to bring up the plants; when they are fit to remove, they should be each put into a separate small pot, filled with loamy earth, and shaded until they take root; then they may be placed with other hardy exotic plants in a sheltered situation, and in October they must be removed into the green-house; and treated as other plants from the same country. It flowers in July and August.

The seeds of the third sort were sent me from Campeachy; this hath a perennial root, which puts out several channelled herbaceous stalks, which rise about two feet high; and toward the top divide into two or three small branches, garnished with oval leaves four inches long and three broad, having several transverse ribs on their under side, which are prominent. The flowers come out from between the leaves on short foot-stalks; they are white, and shaped like

F f those

A V E

those of the common sort, but are smaller. It flowers in July and August, but seldom ripens its fruit in England. It is propagated by parting the roots in the spring, and the plants must be kept in the bark-stove to have them thrive well in this country.

A V E N A. Lin. Gen. Plant. 85. Tourn. Inst. R. H. 514. Oats.

The CHARACTERS are,

The flowers are collected in a loose panicle, without beards; these have a bivalvular empalement, swelling in the middle, and pointed at both ends. The petal of the flower is bivalve, the lower valve being of the same size with the empalement, but harder, putting out from the back a spiral beard, twisting, jointed, and reflexed. There are two oval nectarii sitting upon the upper side of the germen, which is obtuse, supporting two reflexed hairy styles, crowned by two plain stigma; these are attended by three slender stamina, crowned by oblong forked summits. The germen afterward becomes an oblong swelling seed, pointed at both ends; having a longitudinal furrow, and closely shut up in the cover or chaff.

This genus of plants is ranged in the second section of Linnaeus's third class, entitled Triandria Digynia, from the flowers having three stamina and two styles.

A V E N A (*Dispermis*) calycibus dispermibus feminibus laevibus. Hort. Cliff. 25. Oats with two smooth seeds in each empalement. There are three sorts of these Oats cultivated in England, viz. the white, the black, and the brown or red Oat, which are supposed to be only accidental varieties; but where they have been many years separately cultivated, I have never observed them to alter. However, as their principal difference is in the colour of their grain, I shall not enumerate them as distinct species. There is also a naked Oat, which is sometimes cultivated in the distant parts of England, but is rarely seen near London.

The white sort is the most common about London; the black is more cultivated in the northern parts of England, and is esteemed a very hearty food for horses; but the first makes the whitest meal, and is chiefly cultivated where the inhabitants live much upon Oat-cakes.

The naked Oat is less common than either of the others, especially in the southern parts of England; but in the north of England, Scotland, and Wales, it is cultivated in plenty. This sort is esteemed, because the grain threshes clean out of the husk, and need not be carried to the mill to be made into oatmeal or grist. An acre of ground doth not yield so many bushels of these, as of the common Oats, by reason the grain is small and naked, and goes near in measure; but what is wanting in the measure, is supplied in value.

The red Oats are much cultivated in Derbyshire, Staffordshire, and Cheshire, but are rarely seen in any of the counties near London; though, as they are a very hardy sort, and give a good increase, they would be well worth propagating, especially for all strong lands.

The straw of these Oats is of a brownish red colour, as is also the grain, which is very full and heavy, and esteemed better food for horses than either of the former sorts.

Oats are a very profitable grain, and absolutely necessary, being the principal grain which horses love; and are esteemed the most wholesome food for those cattle, being sweet, and of an opening nature; other sorts of grain being apt to bind, which is injurious to labouring horses: but if you feed them with this grain soon after they are housed, before they have sweat in the mow, or are otherwise dried, it is as bad on the other hand, for they are then too laxative.

This grain is a great improvement to many estates in the north of England, Scotland, and Wales; for it will thrive on cold barren soils, which will produce no other sort of grain; it will also thrive on the hottest land: in short, there is no soil too rich or too poor for it, too hot or too cold for it; and in wet harvests, when other grain is spoiled, this will receive

A V E

little or no damage; the straw and husks being of so dry a nature, that if they are housed wet, they will not heat in the mow, or become mouldy, as other grain usually do; so is of great advantage in the northern parts of England, and in Scotland, where their harvest is generally late, and the autumns wet.

The meal of this grain makes tolerable good bread, and is the common food of the country people in the north. In the south it is esteemed for pottage, and other messes, and in some places they make beer with this grain.

The best time for sowing of Oats is in February or March, according as the season is early or late; and sometimes I have known it sown in April upon cold land, and has been early ripe. The black and red Oats may be sown a month earlier than the white, because they are hardier.

Oats are often sown on land which has the former years produced Wheat, Rye, or Barley. The common method is to plough in the stubble about the beginning of February, and sow the Oats, and harrow them in; but then they must be harrowed the same way as the furrows lay, for if it be done crossways, the stubble will be raised on the surface; but this is not a good method of husbandry, for when people have time to plough the stubble in autumn, it will rot in winter; and then giving the land another ploughing and a good harrowing just before the Oats are sown, it will make the ground finer and better to receive the grain. Most people allow four bushels of oats to an acre, but I am convinced three bushels are more than enough; the usual produce is about twenty-five bushels to an acre, though I have sometimes known more than thirty bushels on an acre.

Oats are also sown upon land when it is first broken up, before the ground is brought to a tilth for other grain, and is frequently sown upon the sward with one ploughing; but it is much better to give the sward time to rot before the Oats are sown, for the roots of the grass will prevent those of the Corn from striking downward.

A V E N U E S are walks of trees leading to a house, which are generally terminated by some distant object.

These were formerly much more in request than at present, there being few old seats in the country but have one or more of these avenues; and some have as many of them as there are views from the house; but of late these are, with good reason, disused; for nothing can be more absurd, than to have the sight contracted by two or more lines of trees, which shut out the view of the adjacent grounds, whereby the verdure and natural beauties of the country are lost; and where the avenues are of a considerable length (even where their breadth is proportionable) they appear at each end to be only narrow cuts through a wood, which never can please any person of real taste; and, when the road to the house is through the avenue, nothing can be more disagreeable; for in approaching to the house, it is like going through a narrow lane, where the objects on each side are shut out from the view; and when it is viewed from the house, it at best has only the appearance of a road, which being extended to a length in a straight line, is not near so beautiful as a common road, which is lost by the turnings, so as seldom to be seen to a great extent: but as these avenues must be made exactly straight, so when the trees are grown to any size, they entirely break the view, whatever way the sight is directed through them; and if this is in a park, the lawn of grass through which the avenue is planted, is thereby entirely deprived of the beauty which it naturally would afford, if left open and well kept: therefore, whenever the situation of a house will admit of a large open lawn in front, the road to the house should be carried round at a proper distance; and, if it be carried sometimes through trees, and serpented in an easy natural way, it will be much more beautiful than any stiff formal avenue, how large soever made.

But

A V E

But as there may be some persons so much wedded to the old way of laying out and planting grounds, as to prefer the avenues to the most beautiful disposition of lawns, woods, &c. I shall mention the usual methods of designing and planting them, that have been esteemed the best.

The usual width allowed to these avenues was generally as much as the whole breadth of the house and wings; but if they are planted twelve or fourteen feet wider, they will be the better; because when the trees are grown to any considerable size, they will spread and overhang, so will contract the view.

And as for such avenues to woods or prospects, &c. they ought not to be less than sixty feet in breadth; and because such walks are a long time before they are shady, it will be convenient to plant another row on each side, rather than to lose the stateliness that the main walk will afford in time by being broad, where any thing of a prospect is to be gained.

And as to the distance one from another, they should not be planted nearer one another than thirty-five or forty feet, especially if the trees are of a spreading kind; and the same distance, if they are for a regular grove.

As to the trees proper for planting avenues, they may be the English Elm, the Lime-tree, the Horse Chestnut, the common Chestnut, the Beech, and the Abele.

The English Elm is approved for all places where it will succeed, and that it will do in most places, except in very wet or cold shallow grounds. 1. Because it will bear cutting, heading, lopping in any manner whatsoever, and probably, with better success than any other tree.

Secondly, the Lime-tree: this is approved by others, because it will do well in any tolerable soil, if the bottom be not hot and gravelly; and because of the regular shape it has in growing, the agreeableness of its shade, and the beautiful colour of its leaves.

Thirdly, the Horse Chestnut is also to be used in such places as are very well defended from strong winds; because, wherever it grows freely, if it be not skilfully managed now and then by cutting, the branches are subject to split down. This tree is valuable on account of its quick growth, the earliness of its coming out, the nobleness of its leaves, and the beauty of its flowers, being a fine plant both for shade and ornament. This delights in a strong hearty soil, but will do well in any tolerable ground, if good care be taken in the planting of it; but wherever these trees are planted in avenues, they should be placed thirty feet asunder, that their heads may have room to spread, otherwise they will not appear so beautiful.

Fourthly, the common Chestnut will do well in a proper soil, and will rise to a considerable height, if planted close together; but if it be planted singly, where the tree can take its own natural shape, it is rather inclined to spread and grow globous than tall.

Fifthly, the Beech is recommended by some; but this seldom succeeds well after transplanting, without extraordinary care; though it arrives to a very large tree in many places in England, where it grows naturally; and is the most tedious and troublesome to raise, to any tolerable size, in a nursery way.

Sixthly, the Abele: this, indeed, grows more dispersed and loose in its head than any of the former, and consequently, is worse for defence; but yet is not to be left out from the number of trees for avenues, because it is the quickest in growth of all the forest trees, and will thrive tolerably well in almost any soil, and particularly in wet ground, where few of the before-mentioned trees will thrive, and this seldom fails in transplanting.

Seventhly, the Oak; but this is seldom used in planting avenues, because it requires so long a time to raise it up to any tolerable stature in the nursery way; nor is it apt to thrive much after it has been transplanted, if at any bigness.

As for the Alder, Ash, Platanus, and Sycomore, they are but rarely used for planting avenues.

A U R

AURANTIUM [this plant is so called from aurum, Lat. gold, on account of its golden colour,] the Orange-tree.

The CHARACTERS are;

The empalement of the flower is small, of one leaf, indented in five parts. The flower hath five oblong spreading petals, and many stamina, which are frequently joined in small separate bodies at bottom, and are crowned by oblong summits. In the center is situated the round germen, supporting a cylindrical style, crowned by a globular stigma. The germen afterward becomes a globular fleshy fruit, compressed at both ends, having a thick fleshy pulp, and divided into several cells, each containing two oval callous seeds.

This genus of plants, is by Dr. Linnæus joined to the Citron, to which he has also added the Lemon, making them only species of the same genus, and ranges it in his eighteenth class, entitled Polyadelphia Icolandria, the flowers having more than twenty stamina, which are joined in several bodies.

The SPECIES are,

1. **AURANTIUM** (*Acridi*) foliis ovato-lanceolatis glabris. Orange-tree, with oval, spear-shaped, smooth leaves. Aurantium acridi medullâ vulgare. Ferr. Hesp. *The Seville Orange.*
2. **AURANTIUM** (*Sinense*) foliis lanceolatis acutis glabris. Orange-tree, with pointed, spear-shaped, smooth leaves. Aurantium Sinense. Ferr. Hesp. *The China Orange.*
3. **AURANTIUM** (*Oriente*) foliis lineari-lanceolatis glabris. Orange-tree with narrow, spear-shaped, smooth leaves. Aurantium angustifolium dictum. Boerh. Ind. alt. 2. 238. *Willow-leaved Orange, and by some called the Turkey Orange.*
4. **AURANTIUM** (*Decumana*) foliis ovato-lanceolatis crassis lucidis, fructu maximo. Orange-tree with thick, shining, oval, spear-shaped leaves, and a large fruit. Aurantium fructu maximo Indiæ Orientalis. Boerh. Ind. alt. 2. 238. *The Pumpmoes, or Shaddock.*
5. **AURANTIUM** (*Humile*) pumilum foliis ovatis floribus sessilibus. Dwarf Orange-tree with oval leaves, and flowers growing close to the branches. Aurantium pumilum sub acridi medullâ. Bartol. *The Dwarf, or Nutmeg Orange.*

There are many varieties of this, as there is of most other fruits which have arisen from culture; but those here enumerated may strictly be allowed to be distinct species. The varieties in the English gardens are, 1. The yellow and white striped-leaved Orange. 2. The curled-leaved Orange. 3. The horned Orange. 4. The double flowering Orange. And 5. The hermaphrodite Orange.

The China Orange is not so hardy as the Seville, therefore must be treated more tenderly, placing it in winter in the warmest part of the green-house, and housing it earlier in autumn, otherwise the fruit will all drop from the trees. This sort rarely produces good fruit in England, nor are the leaves of the tree near so large or beautiful as those of the Seville Orange; therefore the latter should be preferred, and only a tree or two of the China sort kept for variety.

The Dwarf Orange is also tender, the leaves are very small, growing in clusters; the joints of the branches are very near each other, and the flowers of these grow very close together, and appear like a nosegay, the branches being covered with them. This sort, when in flower, is proper to place in a room or gallery, to adorn them; the flowers being very sweet, will perfume the air of the place; but these are seldom to be found in good health, because they must be treated with more care than the common Orange and Lemon-trees, as must also the Shaddock, otherwise the fruit will always drop off in winter. The Pumpmoes was brought from the East-Indies by one Capt. Shaddock, from whom the inhabitants of the West-Indies gave this fruit the name. But they have greatly degenerated the fruit since it has been in the West-Indies, by raising the trees from seeds; the greatest part of which produce harsh sour fruit, greatly inferior to the original sort; the flesh or pulp of which is red, whereas the greater part of the trees in America

rica produce fruit with a pale yellow flesh, and by constantly raising these trees from seeds, they degenerate the fruit continually; whereas, if they would bud from the good sort, they might have it in as great plenty as they pleased; but there are few persons in that part of the world who understand the method of grafting or budding fruit trees, and if they did, they are so negligent of their fruits, &c. as to leave the whole to nature, seldom giving themselves any farther trouble than to put the seeds into the ground, and leave them to grow as nature shall incline.

In proof of what I have here said, I cannot omit to mention, that a few years ago, I sent two small trees of the true Seville Orange to Jamaica, where this sort was wanting; and from these many other trees were budded, which have produced plenty of fruit, some of which were sent to England a few years past; and although they were long in their passage, yet when they arrived here, they were greatly superior to any of those fruit which are imported hither from Spain or Portugal, one of those affording three times the quantity of juice, that a fruit of equal size from either of those countries does.

All the sorts of Orange-trees with striped leaves are tender, therefore must be placed in a warm part of the green-house in winter, and must be treated with more care than the common sort, otherwise they will not thrive. These are varieties which some persons are fond of, but they never produce good fruit, nor are the flowers produced in so great plenty, therefore a few only should be preserved for the sake of variety.

The horned Orange differs from the other sorts in the fruit dividing into parts, and the rind expanding in form of horns: this and the distorted Orange are preserved by some curious persons for variety, but are not so beautiful as the common Orange. There is also a great variety of sweet Oranges both in the East and West-Indies, some of which are much more esteemed than those we now have in Europe; but as they are much tenderer, they will not thrive in this country with the common culture; therefore I shall not enumerate them, but shall proceed to give directions for the management of Orange-trees in England.

Where the trees are to be raised for stocks to bud Oranges, you should procure some Citron-seeds which were duly ripened; for the stocks of this kind are preferable to any other, both for quickness of growth, as also that they will take buds of either Orange, Lemon, or Citron; next to these are the Seville Orange seeds. The best seeds are usually to be had from rotten fruits, which are commonly easy to be procured in the spring of the year; then prepare a good hot-bed, of either horse-dung or tanners bark; the last of which is much the better, if you can easily procure it. When this bed is in a moderate temper for heat, you must sow your seeds in pots of good rich earth, and plunge them into the hot bed; observing to give them water frequently, and raise the glasses in the great heat of the day, to give proper air, lest the seeds should suffer by too great heat: in three weeks time your seeds will come up, and if the young plants are not stunted, either for want of proper heat or moisture, they will be in a month's time after their appearance, fit to transplant into single pots: you must therefore renew your hot-bed, and having prepared a quantity of small halfpenny pots (which are about five inches over at the top,) fill these half full of good fresh earth, mixed with very rotten cow-dung; and then shake out the young plants from the large pots, with all the earth about them, that you may the better separate the plants without tearing their roots; and having half filled the pots with earth, put a single plant into each of the small pots; then fill them up with the same earth as before directed, plunging the pots into the new hot-bed, giving them a good watering to fix the earth to their roots; and observe to repeat the same very often (for this plant, when in a hot-bed, requires much water,) but be sure

to screen them from the sun in the heat of the day. In this method, with due care, your plants will grow to be two feet high by July, when you must begin to harden them by degrees, in raising your glasses very high, and when the weather is good, take them quite off; but do not expose them to the open sun in the heat of the day, but rather take off the glasses, and shade the plants with mats, which may be taken off when the sun declines; for the violent heat in the middle of the day would be very injurious to them, especially while young. Toward the end of September you must house them, observing to place them near the windows of the green-house, to prevent the damps from moulding their tender shoots. During the winter season they may be often refreshed with water, and in March or April, wash their heads and stems, to clear them from the filth that may have settled thereon, during their being in the house; and you must also give them a moderate hot-bed in the spring, which will greatly forward them; but harden them by the beginning of June, that they may be in right order to bud in August; when you should make choice of cuttings from trees that are healthy and fruitful, of whatever kinds you please, observing that the shoots are round; the buds of these being much better and easier to part from the wood, than such as are flat. When you have budded the stocks, you should remove them into a green-house, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and refresh them often with water. In a month's time after budding, you will see which of them has taken; you must then untie them, that the binding may not pinch the buds, and let them remain in the green-house all the winter; then in the spring, prepare a moderate hot-bed of tanners bark; and, after having cut off the stocks about three inches above the buds, plunge their pots into the hot-bed, observing to give them air and water, as the heat of the weather shall require; but be sure to screen them from the violence of the sun during the heat of the day. In this management, if your buds shoot kindly, they will grow to the height of two feet or more, by the end of July; at which time you must begin to harden them before the cold weather comes on, that they may the better stand in the green-house the following winter. In the first winter after their shooting, you must keep them very warm; for, by forcing them in the bark-bed, they will be somewhat tenderer; but it is very necessary to raise them to their height in one season, that their stems may be strait: for in such trees, which are two or more years growing to their heading height, the stems are always crooked. In the succeeding years, their management will be the same as in full grown trees, which will be hereafter treated of: I shall therefore, now, proceed to treat of the management of such trees as are brought over every year in chests from Italy; which is, indeed, by much the quicker way of furnishing a green-house with large trees; for those which are raised from seeds in England, will not grow so large in their stems under eighteen or twenty years, as these are when brought over; and although their heads are small when we receive them, yet in three years, with good management, they will obtain large heads and produce fruit.

In the choice of these trees observe first, the difference of their shoots and leaves (if they have any upon them) to distinguish their different sorts, for the Shaddock and Citrons always make much stronger shoots than the Orange; for which reason, the Italian gardeners, who raise these trees for sale, generally propagate those sorts, so that they bring few of the Seville Orange-trees over, which are much more valuable both for their flowers and fruit; also prefer those that have two good buds in each stock (for many of them have but one, which will always produce an irregular head:) the straightness of the stem, freshness of the branches, and plumpness of the bark, are necessary observations.

A U R

When you have furnished yourself with a parcel of trees, you must prepare a moderate hot-bed of tanners bark, in length and breadth according to the number of trees to be forced; then put your trees into a tub of water upright, about half way of the stems, leaving the head and upper part of the stem out of the water, the better to draw and imbibe the moisture. In this situation they may remain two or three days (according to their plumpness when you received them;) then take them out, and clean their roots from all filth, cutting off all broken or bruised roots, and all the small fibres, which are quite dried by being so long out of the earth, and scrub the stems with a hard hair-brush, cleaning them afterwards with a cloth; then cut off the branches about six inches from the stem, and having prepared a quantity of good fresh earth, mixed with very rotten neats dung, plant your trees therein, observing never to put them into large pots; for if they are but big enough to contain their roots, it is sufficient at first planting; and be sure to put some potsherds and large stones in the bottom of each pot, to keep the holes at the bottom of the pots from being stopped with earth, that the water may freely pass off, and wrap some haybands round their stems, from bottom to top, to prevent the sun from drying their bark; then plunge these pots into the bark-bed, watering them well to settle the earth to their roots, frequently repeating the same all over their heads and stems, being very careful not to over-water them, especially before they have made good roots; and observe to screen the glasses of your hot-bed from the sun in the heat of the day.

If your trees take to grow kindly (as there is little reason to doubt of, if the directions given be duly observed,) they will have made strong shoots by the beginning of June; at which time you should stop their shoots, to obtain lateral branches to furnish their heads; and now you must give them air plentifully, and begin to harden them, that in the middle of July they may be removed into the open air, in some warm situation, defended from the great heat of the sun, and from winds, that they may be hardened before winter. About the end of September you should house these plants, setting them at first in the front of the green-house, near the glasses, keeping the windows open at all times when the weather will permit; and about the latter end of October, when you bring in the Myrtles, and other less tender trees, you must set your Oranges in the warmest and best part of the house, placing lower plants or trees in the front, to hide their stems. During the winter, let your waterings be frequent, but give them not too much at a time; for now their heads are but small, and therefore incapable to discharge too great a quantity of moisture, and take great care to guard them from frost.

In the spring, when you begin to take out some of your hardiest sorts of plants to thin your house, wash and cleanse the stems and leaves of your Orange-trees, taking out the upper part of the earth in the pots, filling them up again with good, fresh, rich earth, laying thereon a little rotten neats dung round the outside of the pots, but do not let it lie near the stem of the trees; then place them at wider distances in the house, that the air may circulate round their heads, giving them air discretionally, as the weather grows warm; but do not remove them into the open air until the latter end of May, that the weather is settled; for many times, when they are removed out too soon, the mornings often proving cold, give them at least a great check, which will change the colour of their leaves, and many times kill the extreme weak part of the shoots. Let the situation for your Orange-trees, during the summer season, be as much defended from the sun in the heat of the day, and strong winds, as possible, by tall trees or hedges; both of which, if they are exposed thereto, are very hurtful to them.

As these trees advance, it will be necessary in the

A U R

summer to stop strong shoots where they grow irregularly, to force out lateral branches to fill the head; but do not pinch off the tops of all the shoots (as is the practice of some,) which will fill the tree with small shoots too weak to support fruit; but endeavour to form a regular head, and obtain strong shoots, taking away weak trifling branches where they are too close.

During the summer season, your Orange-trees will require frequent waterings in dry weather, especially if they are large; therefore you should endeavour to have the water as near the trees as possible, to save the trouble of carrying it, which, in a large quantity of trees, takes up much time. Your water should be soft, and exposed to the air; but never add dung of any sort thereto; which, although by many frequently recommended, yet has always been found destructive to these, and all other trees, if much used; it being like hot liquors to human bodies, which, at first taking, seem to add vigour, yet certainly leave the body weaker after some time than before.

Your Orange-trees will require to be shifted and new potted every other year, therefore you must prepare a quantity of good earth, at least a year before you intend to use it, that it may be well mixed and perfectly rotten. The best season for this work is about the end of April, that they may have taken fresh root before they are removed out of the green-house; and when this work is performed, it will be necessary to let them remain in the house a fortnight longer than usual, to be well settled.

In the performing this work, after you have drawn the trees out of the pots, you must cut off all the roots round the outside of the ball of earth, and take away all mouldy roots (if any such be;) then with a sharp iron instrument, get as much of the old earth from between the roots as possible, being careful not to break or tear the roots; then set the root of the tree into a large tub of water for about a quarter of an hour, to soak the under part of the ball of earth; and afterwards scrub the stems of the trees with a hard hair-brush, cleaning them and the heads with water, and a soft woollen cloth. Your pots being prepared, with some potsherds and large stones in the bottom, put some of your fresh earth into the pot, about three or four inches thick; and having placed your tree thereon, in the middle of the pot, upright, fill it up with the same rich earth, pressing it down hard with your hands; then water the tree all over the head, with a watering-pot that has a rose upon the spout, to let the water fall light and thick (as in a shower of rain;) and in watering these trees, do it in the same manner, during the time they abide in the house after shifting; this will greatly refresh their heads, and promote their taking fresh roots.

When you first set these trees abroad after shifting, you should place them near the shelter of hedges, and fasten their stems to strong stakes, to prevent their being disturbed by winds, which sometimes will blow fresh planted trees out of the pots, if too much exposed thereto, and thereby greatly injure their new roots.

If old Orange-trees have been ill managed, and their heads become ragged and decayed, the best method to restore them, is to cut off the greatest part of their heads early in March, and draw them out of the tubs or pots, and shake off the earth from their roots, cutting away all small fibres and mouldy roots; and then soak and clean their roots, stems, and branches, planting them in good earth, and setting them into a hot-bed of tanners bark, as was directed for such trees as came from abroad, managing them in the same manner: by this method they will produce new heads, and in two years time become good trees again. But if these are large trees, and have grown in tubs for several years, your best way will be to prepare a parcel of rough baskets (such as are used for basketing Evergreens, when sent to a distant place:) let these be somewhat less than the tubs you design to plant your trees into; then plant your trees

G g

herein,

herein, plunging them into the hot-bed, and about the beginning of July, when your trees have made good shoots, you may remove them into the tubs, with their baskets about them, filling the empty space with the same good earth: this will preserve your tubs from rotting in the bark, and the trees will do equally well as if planted into the tubs at first, provided you are careful in removing the baskets; not to disturb their roots; and also let them remain in the green-house a fortnight or three weeks after planting, before you set them abroad.

These trees being new potted or tubbed every other year, those years in which they are not shifted, you must in April observe to take out as much of the old earth from the tops of the pots and tubs, and also round the sides of them, as possible, without injuring the roots of the trees, and fill them up with fresh earth; you must also wash and clean their stems and leaves from filth, which will greatly strengthen their flowering, and cause them to shoot vigorously the following summer.

In the management of Orange-trees which are in good health, the chief care should be to supply them with water duly, and not (as is sometimes practised) starve them in winter, whereby their fibres are dried, and become mouldy, to the great prejudice of the trees; nor to give them water in too great abundance, but rather let their waterings be frequent, and given in moderate quantities. You must also observe, that the water has free passage to drain off; for if it be detained in the tubs or pots, it will rot the tender fibres of the trees. During the winter season, they must have a large share of air when the weather is favourable; for nothing is more injurious to these trees than stifling of them, nor should they be placed too near each other in the green-house; but set them at such distance, that their branches may be clear of each other, and that the air may circulate freely round their heads. In summer they should be placed where the winds are not violent, and to have the morning and evening sun; for if they are too much exposed to the mid-day sun, they will not thrive. The best situation for them is near some large plantation of trees, which will break the force of the winds, and screen them from the violent heat of the sun. In such a situation they may remain until the beginning of October, or later, according as the season proves favourable; for if they are carried into the green-house early, and the autumn should prove warm, it will occasion the trees to make fresh shoots, which will be weak and tender, and so liable to perish in winter; and sometimes it will occasion their flowering in winter, which greatly weakens the trees; nor should they remain so long abroad as to be injured by morning frosts. The best compost for Orange-trees is two thirds of fresh earth from a good pasture, which should not be too light, nor over stiff, but rather a hazel loam; this should be taken about ten inches deep with the sward, which should be mixed with the earth to rot, and one third part of neats dung; these should be mixed together, at least twelve months before it is used, observing to turn it over every month, to mix it well, and to rot the sward; this will also break the clods, and cause the mould to be finer. Before you make use of this earth, you should pass it through a rough screen, to separate the great stones and the roots of the sward therefrom; but by no means sift the earth too fine, for this is very prejudicial to most plants, but particularly to Orange-trees.

Of late years there have been many of these trees planted against walls, against which frames of glass are made to fix over them in winter; and some few curious persons have planted these trees in the full ground, and have erected moveable covers to put over the trees in winter, which are so contrived as to be all taken away in summer: where these have been well executed, the trees have made great progress in their growth, and produced a much larger quantity of fruit, which have ripened so well, as to be extremely good for eating. If these are planted either against walls with

design of training the branches to the walls, or in borders at a small distance, so as to train them up as standards, there should be a contrivance of a fire-place or two, in proportion to the length of the wall, and flues carried the whole length of the wall, to warm the air in very cold weather, otherwise it will be very difficult to preserve the trees in very hard winters alive; or, if they do live through the winter, they will be so much weakened by the cold, as not to be recovered the following summer to a proper strength for bearing; so that wherever the trees are intended to be placed against or near old walls, the flues should be built up against the front, allowing four inches thickness of the brick-work on each side the flues, observing to fasten this with irons, at proper distances, to secure it from separating from the old wall: the manner of making these flues, is fully explained under the article of HOT WALLS. Where this contrivance is made, there will be no hazard of losing the trees, be the winter ever so severe, with a little proper care; whereas, if this is wanting, there will require great care and trouble to cover and uncover the glasses every day, when there is any sun; and if the wall is not thicker than they are usually built, the frost will penetrate through the walls in severe winters; so that covering and securing the glasses of the front will not be sufficient to preserve the trees, be it done with ever so much care; therefore the first expence of the walls will save great trouble and charge, and be the securest method.

If the ground is wet, or of a strong clay, so as to detain the moisture, the borders should be raised above the level of the ground, in proportion to the situation of the place; for where the wet lies in winter near the surface, it will greatly prejudice, if not totally destroy the trees; so that lime rubbish should be laid at least two feet thick in the bottom of the border, to drain off the wet; and the earth should be laid two and a half or three feet thick thereon, which will be a sufficient depth for the roots of the trees. In these borders there may be a few roots of the Guernsey and Belladonna Lilies and Hæmanthus planted, or any other exotic bulbous-rooted flowers, which do not grow high, or draw too much nourishment from the borders; and these, producing their flowers in autumn or winter, will make a good appearance, and thrive much better than if kept in pots.

The management of the Orange-trees in these places, is nearly the same as hath been directed for those in pots or tubs, excepting that the borders in these places should be dug, and refreshed with some very rotten dung every year.

AURICULA MURIS, or **PILOSELLA**. Mouse Ear. This is a sort of Hawkweed with small hairy leaves, which are white underneath: the plant trails upon the ground, taking root at the joints, by which means it will soon spread over a large compass of ground.

This is very common in England; it grows chiefly on dry barren places, or upon old walls, and is too often a troublesome weed in grass-plats in gardens.

AURICULA URSI [i. e. Bear's Ear, so called because the ancients fancied it resembled the ear of a bear.] Bear's Ear, or Auricula.

Dr. Linnæus has joined this genus to the *Primula veris* of Tournefort, making this one species under the title of *Primula*.

To enumerate the diversities of this plant, would be almost endless and impossible; for every year produces vast quantities of new flowers, differing in shape, size, or colour of the flowers; and also in the leaves of these plants there is as great a variety, so that the skilful florist is oftentimes capable of distinguishing many of the particular sorts thereby.

But as it seldom happens, that such of these flowers as are at one time in great esteem, continue to be regarded a few years after, (their being still finer or larger flowers produced from seeds, which are what the florists chiefly seek after) it would be needless to mention any of them; wherefore I shall proceed to give the characters of a good Auricula.

A U R

1. *The stem of the flower should be lofty and strong.*
2. *The foot-stalk of the flower should be short, that the umbel may be regular and close.*
3. *The pipe or neck of each flower should be short, and the flowers large, and regularly spread, being no ways inclinable to cup.*
4. *That the colours are very bright, and well mixed.*
5. *That the eye of the flower be large, round, and of a good white, or yellow; and that the tube or neck be not too wide.*

All the flowers of this kind that want any of the above-mentioned properties, are now rejected by every good florist; for as the varieties every year increase from seeds, the bad ones are turned out to make room for their betters; but in some people the passion for new flowers so much prevails, that, supposing the old flower greatly preferable to a new one, if it is of their own raising, the latter must take place of the old one.

In order to obtain good flowers from seeds, you must make choice of the best flowers you have, which should be exposed to the open air, that they may have the benefit of showers, without which they seldom produce good seeds: the time of their ripening is in June, which you will easily know, by their seed-vessel turning to a brown colour, and opening; you must therefore be careful lest the seeds be scattered out of the vessel, for it will not be all fit to gather at the same time.

The time for sowing this seed is commonly in August, but if it be sown any time before Christmas, it will be time enough.

The best soil for this seed is good, fresh, sandy mould, mixed with very rotten neats dung, or very rotten dung from the bottom of an old hot-bed: with this you should fill your pots, boxes, or baskets, in which you intend to sow your seeds: and having levelled the surface of the earth very smooth, sow your seeds thereon, covering it very lightly with rotten Willow mould taken out of the stems of decayed hollow Willow-trees; then cover the box, &c. with a net or wire, to prevent the cats, birds, &c. from scratching out, or burying the seeds too deep; for whenever this happens, the seeds will remain a year in the ground before the plants appear, if it should grow at last; for which reason many persons never cover these seeds, but leave them upon the surface of the earth, in the boxes, for the rain to wash them into the ground, which is often the best method: let these boxes, &c. be placed so as to receive half the day's sun, during the winter season; but in the beginning of March, remove them where they may only have the morning sun till ten of the clock; for the young plants will now soon begin to appear, which, if exposed to one day's whole sun only, will be all destroyed.

During the summer season, in dry weather, often refresh them with water, but never give them too great quantities at once. In the July following, your plants will be large enough to transplant, at which time you must prepare a bed, or boxes, filled with the above-mentioned soil, in which you may plant them about three inches square; and (if in beds) you must shade them every day, till they are thoroughly rooted, as also in very hot dry weather; but if they are in baskets or boxes, they may be removed to a shady place.

When the seedling Auriculas are planted in beds, there should be some rotten neats dung laid about ten inches under the surface, and beaten down close and smooth: this will prevent the worms from drawing the young plants out of the earth, which they generally do where this is not practised. This dung should be laid about half a foot thick, which will entirely prevent the worms getting through it until the plants are well established in the beds; and the roots of the Auriculas will strike down into the dung by the spring, which will make their flowers stronger than usual: these beds should be exposed to the east, and screened from the south sun.

A U R

When you have taken all your plants, which are now come up, out of your boxes or pots, level the earth gently again; for it often happens, that some of the seeds will lie in the ground two years before they appear, especially if they were covered too deep when sown, as was before observed.

The spring following many of these flowers will shew, when you may select such of them as have good properties, which should be removed each of them into a pot of the same prepared earth, and preserved until the next season, at which time you will be capable to form a judgment of the goodness of the flower; but those that produce plain-coloured or small flowers, should be taken out, and planted in borders in the out-parts of the garden, to make a shew, or gather for nosegays, &c. the others, which do not produce their flowers the same year, may be taken up, and transplanted into a fresh bed, to remain till you see how they will prove.

The manner of propagating these flowers when obtained, is from offsets, or slips, taken from the old roots in April, when the flowers are in bloom: these offsets must be planted into small pots filled with the same sort of earth as was before directed for the seedlings, and, during the summer season, should be set in a shady place, and must be often (but very gently) refreshed with water; but in the autumn and winter should be sheltered from violent rains. The spring following these young plants will produce flowers, though but weak; soon after they are past flowering, you must put them into larger pots, and the second year they will blow in perfection.

But, in order to obtain a fine bloom of these flowers, you must observe the following directions.

First, Preserve your plants from too much wet in winter, which often rots and spoils them; but let them have as much free open air as possible; nor should they be too much exposed to the sun, which is apt to forward their budding for flower too soon; and the frosty mornings, which often happen in March, thereby destroy their buds, if they are not protected therefrom. To prevent which, those who are very curious in these flowers, place their pots in autumn under a common hot-bed frame, where, in good weather, the plants may enjoy the full air, by drawing off the glasses; and in great rains, snow, or frost, the plants may be screened by covering them. Where this method is practised with judgment, the flowers will be much stronger, and the plants will increase faster than when they are exposed abroad.

Secondly, In the beginning of February, if the weather is mild, you must take off the upper part of the earth in the Auricula pots, as low as you can without disturbing their roots, and fill up the pots with fresh rich earth, which will greatly strengthen them for bloom; as also prepare your offsets for transplanting in April, by causing them to push out new roots.

Those plants which have strong single heads, always produce the largest clusters of flowers; therefore the curious florists pull off the offsets as soon as it can be done with safety to their growing, to encourage the mother plants to flower the stronger; they also pinch off the flowers in autumn, where they are produced, and suffer them not to open, that the plants should not be weakened thereby.

Thirdly, You must cover your pots with mats in frosty weather, during this time of their budding for flower, lest the sharp mornings blight them, and prevent their blowing.

Fourthly, When your flower-stems begin to advance and the blossom buds grow turgid, you must protect them from hasty rains, which would wash off their white mealy farina, and greatly deface the beauty of their flowers; but at the same time observe to keep them as much uncovered as possible, otherwise their stems will be drawn up too weak to support their flowers (which is often the case when their pots are placed near walls) give them gentle waterings to strengthen them, but let none of the water fall into the center of the plant, or among the leaves.

Fifthly,

A Z A

Fifthly, When your flowers begin to open, you should remove their pots upon a stage (built with rows of shelves, one above another, and covered on the top, to preserve them from wet: this should be open to the morning sun, but sheltered from the heat of the sun in the middle of the day :) in this position they will appear to much greater advantage, than when the pots stand upon the ground; for, their flowers being low, their beauty is hid from us; whereas, when they are advanced upon shelves, we see them in a full view. In this situation they may remain until the beauty of their flowers is past, when they must be set abroad to receive the rains, and have open free air, in order to obtain seeds, which will fail if they are kept too long under shelter. When your seed is ripe, observe to gather it when it is perfectly dry, and expose it to the sun in a window upon papers, to prevent its growing mouldy, and let it remain in the pods till the season for sowing it.

AURICULA URSI MYCONI. See VER-BASCUM.

AXIS of a plant. Axis is properly that round smooth cylinder, about which a wheel is turned; whence, by way of metaphor, that long, round, smooth part, placed in the center of the juli, or cat tails, on Nut-trees, &c. about which the male organs are disposed, may be called the Axis. The French call it Ame, Noyau, or Poinçon.

AZALEA. Lin. Gen. Plant. 195. American up-right Honeysuckle.

The CHARACTERS are,

It hath a small coloured empalement which is permanent, cut into five acute parts at the top. The flower is funnel-shaped, having a long naked tube, cut into five parts; the two upper segments are reflexed backward, the two sides are bent inward, and the lower one turns downward. It hath five slender stamina of unequal lengths, which have oblong erect summits. The round germen supports a long slender style, crowned with an obtuse stigma; the germen afterward becomes a roundish capsule, having five cells, which are filled with roundish small seeds.

This genus of plants is ranged in the first section of Linnaeus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. **AZALEA** (*Viscosa*) foliis margine scabris, corollis piloso glutinosis. Lin. Sp. Plant. 151. *Azalea with leaves having rough edges, the petals of the flower hairy and glutinous.* Cistus Virginiana flore & odore periclymeni. Pluk. Phyt. tab. 161. f. 4.
2. **AZALEA** (*Nudiflora*) foliis ovatis corollis pilosis staminibus longissimis. Lin. Sp. Plant. 150. *Azalea with oval leaves, hairy flowers, and the longest stamina.* Cistus Virginiana periclymeni flore ampliori minus odorato. Pluk. Mant. 49.

There are three or four other species of this genus, two of which grow naturally upon the Alps, chiefly on bogs; these are low plants, which have little beauty, and very difficult to keep in gardens. The others grow one in the east, near Pontus, and the other in India; but as neither of these are in the English gardens, I shall not enumerate them.

A Z E

The first of these here mentioned, is a low shrub, rising with several slender stems near four feet high. The leaves come out in clusters at the ends of the shoots, without order: they are spear-shaped, but narrow at their base; their edges are set with very short teeth, which are rough. The flowers come out in clusters between the leaves, at the extremity of the branches, which are white, with a mixture of dirty yellow on their outside: they have a tube an inch long, and at the top are pretty deeply cut into five segments; the two upper are reflexed, the two side ones are bent inward, and the lower one is turned downward. There are five slender stamina, which are a little longer than the petals of the flower, supporting oblong Saffron-coloured summits. The style is much longer than the stamina, and crowned by an obtuse stigma. These flowers have much the appearance of those of the Honeysuckle, and are as agreeably scented. They appear the middle of July, but are not succeeded by seeds in England.

The second sort grows taller than the first, and in its native country frequently rises to the height of fifteen feet, but in England is never more than half that height. This sends out several stems from the root, which are garnished with oblong smooth leaves, placed alternately, having foot-stalks. The flower-stalks arise from the division of the branches, which are long and naked, supporting a cluster of red flowers, which are tubulous, swelling at their base like those of the Hyacinth, and contracted at their neck; they are divided at the top into five equal segments, which spread open. The five stamina and the style are much longer than the petals, and stand erect. This flowers about the same time as the former, but is not so well scented.

These plants grow naturally in shade, and upon moist ground in most parts of North America, from whence many of the plants have been sent of late years to England, and several of them have produced their beautiful flowers in many curious gardens.

They must have a moist soil and a shady situation, otherwise they will not thrive. They can only be propagated by shoots from their roots, and laying down their branches, for they do not produce seeds here; and if good seeds could be obtained, they would be difficult to raise, and a long time before they would flower. But when they are in a proper situation, their roots extend, and put out shoots, which may be taken off with roots, and transplanted. When any of them are laid down, it should be only the young shoots of the same year, for the old branches will not put out roots. The best time for this is at Michaelmas, and if they are covered with some old tan, to keep out the frost, it will be of great use to them. The autumn is also the best time to remove the plants, but the ground about their roots should be covered in winter to keep out the frost; and if this is every year practised to the old plants, it will preserve them in vigour, and cause them to flower well.

AZEDARACH. See MELIA.

AZEROLE, or L'AZAROLE. See MESPILUS.

B.

B A C

B ACCA, i. e. a berry, is a round fruit, for the most part soft, and covered with a thin skin, containing seeds in a pulpy substance; but, if it be harder, and covered with a thicker flesh, it is called Pomum, i. e. an Apple.

BACCHARIS, Ploughman's Spikenard, vulgò.

The CHARACTERS are,

The flower is composed of many hermaphrodite and female florets, which are included in one common, cylindrical, scaly empalement. The florets are equal, the hermaphrodite and female are intermixed. The hermaphrodite florets are funnel-shaped and quinquefid, these have five slender stamina, crowned by cylindrical summits, and an oval germen, supporting a slender style, crowned by a bifid stigma. The germen afterward becomes a single short seed crowned with a long down. The female flowers have no stamina, but in other respects are the same.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers being composed of hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. **BACCHARIS** (*Ivaefolia*) foliis lanceolatis longitudinaliter dentato-ferratis. Lin. Hort. Cliff. *Ploughman's Spikenard with spear-shaped leaves, which are longitudinally indented and sawed.* Senecio Africana arborescens folio ferrato. Boerh. Ind. alt. 1. 117.
2. **BACCHARIS** (*Neriifolia*) foliis lanceolatis superne uno alterove denticulo ferratis. Hort. Cliff. 404. *Ploughman's Spikenard with spear-shaped leaves sawed on the edges.* Arbuscula foliis nerii. Boerh. Ind. 2. p. 263.
3. **BACCHARIS** (*Halimifolia*) foliis obovatis superne emarginato-crenatis. Hort. Cliff. 405. *Ploughman's Spikenard with oval indented leaves.* Senecio Virginianus arborescens, atriplicis folio. Raii Hist. 1799.
4. **BACCHARIS** (*Fetida*) foliis lanceolatis ferrato-dentatis, corymbis foliosis. Flor. Virg. 121. *Ploughman's Spikenard with spear-shaped sawed leaves, and a leafy corymbus.* Conyza Americana frutescens foetidissima. Hort. Elth. tab. 89.

The English name of Ploughman's Spikenard has been always applied to the Conyza major, or greater Fleabane; but since most of the modern botanists have applied the title of Baccharis to this genus, I have added the old English name to it, of Ploughman's Spikenard, rather than leave it without an English title. The first sort was brought from the Cape of Good Hope, but grows naturally in Peru, and in other parts of America. This plant has been long preserved by the curious in their gardens. It grows to the height of five or six feet, and is a manageable shrub; it may be propagated by cuttings, which should be planted in a shady border during any of the summer months, or by seeds sown in a common border in the spring of the year. These seeds ripen well in this country; and, if permitted to scatter on the ground, the plants will come up the following spring. It is pretty hardy, and will live abroad in mild winters, if planted in a warm situation; but it is usually kept in green-houses, and placed abroad in summer; it requires much water in warm weather.

The second sort is also a native of Africa; this hath a soft shrubby stalk which rises to the height of eight or ten feet, putting out side branches toward the top, garnished with stiff spear-shaped leaves, having a few indentures toward their top; these are placed without order: the flowers are produced at the extremity of the branches in a close spike, consisting of female and

B A N

hermaphrodite florets included in the common empalement; they are of an herbaceous colour, so make little appearance, and are not succeeded by seeds in England.

This plant is difficult to propagate, for the cuttings do with great difficulty take root; and it is very rare to find shoots near the root to lay down, so that in Holland they lay down the entire head of young plants, sitting the smaller branches in the same manner as is practised for Carnations, laying them into the ground and forking each down to prevent their rising; these when duly watered put out roots in one year, when they may be taken off, and planted in small pots filled with light earth, and placed in the shade till they have taken new root; after which they may be placed in a sheltered situation in summer, but in winter must be kept in a green-house.

The third sort is pretty common in the nurseries about London, where it is usually called the Ground-sell-tree; this is a native of Virginia and other parts of North America; it grows to be a shrub of about seven or eight feet high, and flowers in October; the flowers are white, and not very beautiful; but the leaves continuing green through the year, has occasioned this shrub to be admitted into many curious gardens.

This sort may be propagated by cuttings, which should be planted in April or May, upon a shady border, and duly watered in dry weather, until they have taken root; and, at Michaelmas, they will be fit to transplant where they are to remain; this will live in the open air, and never is injured by the cold of our ordinary winters; but severe frost will sometimes destroy them.

The fourth sort grows naturally in Carolina, and some other parts of North America; it rises with a ligneous stalk six or seven feet high, garnished with long spear-shaped leaves, which are hoary on their under side, having a disagreeable scent when handled; the stalks are terminated by loose umbels of flowers, which appear late in the autumn, so are not succeeded by seeds in this country.

It may be propagated by cuttings, which should be planted toward the end of May, which if shaded and duly watered will put out roots in two months; when they should be potted, that they may be sheltered under a frame in winter.

BACCIFEROUS [Baccifer, Lat. of Bacca, a Berry, and fero, to bear] is an epithet applied to trees, shrubs, or plants, that bear berries, as Briony, Lily of the Valley, Asparagus, Butchers Broom, Nightshade, Solomon's Seal, and many others.

BALAUSTIA. See **PUNICA**.

BALAUSTIUM is the cup of the flower of the wild Pomegranate.

BALLOTE [βαλλοτή, Gr.] Black Horehound.

This is a common weed, growing on the sides of banks in most parts of England, so is seldom allowed a place in gardens; there are two varieties of it, one with a white, and the other a purple flower. As these are not cultivated, I shall not trouble the reader with a farther description of them.

BALM. See **MELISSA**.

BALSAMINA. The female Balsamine. See **IMPATIENS**.

BALSAMITA. See **TANACETUM**.

BAMIA MOSCHATA. See **HIBISCUS**.

BANANA. See **MUSA**.

H h

BANIS-

BANISTERIA. Houst. MSS. Lin. Gen. 509.
Acer Scandens. Sloan. Cat. 137. Plum. Cat. 18.

The CHARACTERS are,

It hath a small permanent empalement, cut into five acute segments to the bottom; the flower hath five petals, which are shaped like those of the papilionaceous tribe, but spread open, having in some species one, in others two, and in some, several nectarious glands. It hath ten short stamina, crowned with simple summits. There are in some species three, and in others but one germen, each supporting a single style, crowned by an obtuse stigma; the germen afterward become so many winged fruit, like those of the Maple, each containing a single seed.

The title of this genus was given by the late Dr. Houstoun, in honour to the memory of Mr. Banister, a curious botanist, who lost his life in the search of plants in Virginia.

The Doctor ranged this genus in the class of papilionaceous flowers, to which it has great affinity by the form of its flower; but the ten stamina standing separate, induced Dr. Linnæus to place it in his tenth class; but although he has put it under his third section, yet it would with greater propriety come under his second, the greater number of species having but two styles.

The SPECIES are,

1. BANISTERIA (*Angulosa*) foliis ovato-oblongis rigidis racemis terminalibus caule fruticoso scandente. *Banisteria with oblong, oval, stiff leaves, spikes of flowers terminating the branches, and a shrubby climbing stalk.* Sir Hans Sloane titles it, *Acer scandens foliis Laurinis.* Cat. Jam. 137.
2. BANISTERIA (*Fulgens*) foliis ovatis glabris, floribus corymbosis terminalibus, caule fruticoso scandente. *Banisteria with oval smooth leaves, flowers growing in a corymbus at the extremity of the branches, and a shrubby climbing stalk.* *Acer scandens minus Apocyni facie folio subrotundo.* Sloan. Cat. 138.
3. BANISTERIA (*Brachiata*) foliis ovatis acuminatis floribus laxè spicatis, ramis diffusis scandentibus. *Banisteria with oval pointed leaves, flowers growing in loose spikes, and climbing diffused branches.* *Banisteria scandens & frutescens folio subrotundo, flore ex aureo Coccineo.* Houst. MSS.
4. BANISTERIA (*Laurifolia*) foliis ovatis nervosis subtus incanis, floribus lateralibus, caule fruticoso scandente. *Banisteria with nervous heart-shaped leaves, hoary on their under side, flowers growing from the side of the branches, and a shrubby climbing stalk.* *Acer Americanum scandens foliis subrotundis subtus pubescentibus.* Millar. Cat.
5. BANISTERIA (*Benghalensis*) foliis ovato-oblongis acuminatis racemis lateralibus seminibus patentibus. Flor. Zeyl. 176. *Banisteria with oblong, oval, pointed leaves, spikes of flowers growing from the side of the branches, and spreading seeds.* *Acer scandens foliis Citrei flore cæruleo spicato.* Plum. Cat. 18.
6. BANISTERIA (*Aculeata*) foliis pinnatis, foliolis oblongis obtusis, floribus spicatis caule ramoso aculeato. *Banisteria with winged leaves, whose small leaves are oblong and blunt, flowers growing in a spike, and a prickly branching stalk.*
7. BANISTERIA (*Purpurea*) foliis pinnatis foliolis ovatis spicis lateralibus seminibus erectis. *Banisteria with winged leaves, whose small leaves are oval, spikes of flowers growing from the side of the branches, and erect seeds.* *Banisteria foliis ovatis spicis lateralibus seminibus erectis.* Lin. Sp. Plant. 427.

The first grows naturally in Jamaica. This hath a woody stalk, which twists itself round the neighbouring trees, and rises to their top. It is garnished with leaves as large as those of the Bay-tree, and of the same thickness, growing opposite; the flowers are produced in long branching spikes at the ends of the branches, which are yellow, composed of five small leaves; these are succeeded by two or three winged seeds like those of the greater Maple.

The second sort grows naturally in Jamaica, at Campeachy, and several other parts of America. This hath slender winding stalks, which rise five or six feet

high, and are thinly garnished with oval smooth leaves; the flowers grow in a round bunch at the extremity of the branches, which are of a brownish yellow colour, and are succeeded by winged seeds like the former, but smaller, and have narrower wings.

The third sort was sent me from Carthage, where it naturally grows. This sends out many branches, which divide again into others, growing without order, and become very bushy upward, sending out tendrils by which they fasten themselves to the neighbouring trees, and mount to a great height; these are garnished with oval stiff leaves, ending in a point. The flowers are produced in loose spikes at the ends of the branches, which are first of a gold colour, and fade to a scarlet. These are succeeded by seeds of the same shape with the former, but are slender, thin, and for the most part single.

The fourth sort was sent me from Campeachy, by Mr. Robert Millar; this hath many irregular climbing stalks, which fasten themselves to the neighbouring trees, and rise to a great height, garnished with oval leaves, which are hairy on their under side, where they have many transverse ribs. The flowers come out thinly from the side of the branches, which are of a pale yellow colour, and are succeeded by large winged seeds, which are double.

The fifth sort hath strong woody stalks, which twine about the trees which grow near it, and rises twenty feet high, garnished with oblong pointed leaves like those of the Bay-tree, growing opposite; from the wings of the leaves the flowers are produced in loose spikes, upon long foot-stalks, which are blue, and are succeeded by slender winged seeds, which spread open from each other.

The sixth sort was sent me from Tolu in New Spain, where it grows naturally. This hath climbing stalks, which divide into many branches, garnished with long winged leaves, composed of about twenty pair of small, oblong, blunt pinnæ, each having a deep furrow on the under side. At the wings of the leaves the stalks are armed with short strong spines, a little crooked. The flowers grow in long loose spikes at the end of the branches, which are succeeded by single seeds, as large as those of the greater Maple.

The seventh sort hath strong ligneous stalks, covered with an Ash-coloured bark, and divide into many branches, garnished with winged leaves, composed of five or six pair of oval small leaves, nearly of the size with those of the common Acacia, but are whitish on their under side; from the wings of the leaves are produced slender bunches of flowers, growing in a racemus like those of the Currant-bush, of a purplish colour; these are succeeded by broad winged seeds, growing erect. It was sent me from Campeachy, where it grows naturally.

These plants are all of them natives of warm countries, so cannot be preserved in England, unless they are kept in a bark-stove. They are propagated by seeds, which must be procured from the countries where they grow naturally. These seeds should be fully ripe when gathered, and put into sand or earth, in which they should be sent to England, otherwise they will lose their vegetative quality; for from a large parcel of these seeds which were sent over in papers, as fresh as they could possibly arrive here, there was very few plants raised, and those did not appear till the second year; for these seeds are not only in shape like those of the Maple, but also are of the same quality, requiring to be sown as soon as possible when they are ripe, or preserved in sand or earth till they are sown, otherwise they rarely succeed; therefore when the seeds arrive, they should be immediately sown in pots, and, if it happens in autumn or winter, the pots should be plunged into a hot-bed of tanners bark, where the heat is very moderate, and secured from frost and wet, till spring, when they must be removed to a fresh hot-bed, which will bring up the plants; but if they should not appear the first year, the pots should be preserved till the next spring,

to see if the seeds will grow. When the plants come up, they must be planted in separate pots, filled with light earth, and plunged into the bark-bed, after which they must be treated like other tender plants from the same countries.

BAOBOB. See ADANSONIA.

BARBACAPRÆ. See SPIRÆA.

BARBA JOVIS. See ANTHYLLIS.

BARBAREA. See ERYSIMUM.

BARDANA. See ARCTIUM.

BARLERIA.

The name was given to this genus of plants by father Plumier, in honour of Jacobus Barlier, of Paris, who was a famous botanist.

The CHARACTERS are,

It hath a permanent empalement, divided into four parts, two large and two smaller, opposite. The flower is of the lip kind, of one leaf, funnel-shaped, and divided into five parts at the top; the upper segment being broad and erect, the two side ones narrower, and the under one which turns downward is divided into two. It hath four slender stamina, two of which are very short; the two upper are longer, crowned by oblong summits. In the center is placed the oval germen, supporting a slender style, crowned by a bifid stigma. The germen afterward becomes an oblong, quadrangular, membranaceous vessel, with two cells, which is very elastic, containing two or three roundish compressed seeds.

This genus of plants is by Dr. Linnæus ranged in the second order of his fourteenth class, titled Didynamia Angiospermia, whose flowers have two long and two short stamina, and their seeds are included in a capsule.

The SPECIES are,

1. BARLERIA (*Solanifolia*) spinis axillaribus foliis lanceolatis denticulatis. Lin. Sp. 887. *Barleria with spines on the side of the branches, and spear-shaped indented leaves.* Barleria aculeata solani folio angustiore flore cæruleo. Plum. N. G. 31.

2. BARLERIA (*Prionitis*) spinis axillaribus quaternis foliis integerrimis. Lin. Sp. Plant. 636. *Barleria with spines growing by fours from the side of the branches, and entire leaves.* Coletta-veetla. Hort. Mal. 9. p. 77.

3. BARLERIA (*Buxifolia*) spinis axillaribus oppositis solitaris, foliis subrotundis integerrimis. Lin. Sp. 887. *Barleria with spines at the wings of the stalk, and roundish entire leaves.* Barleria Americana spinosissima frutescens, buxi folio parvo flore. Amm. Herb. 104.

4. BARLERIA (*Coccinea*) inermis foliis ovatis denticulatis petiolatis. Lin. Sp. 888. *Barleria without spines, and oval indented leaves having foot-stalks.* Barleria solani folio, flore coccineo. Plum. Nov. Gen. 31.

The first sort rises with upright square stalks three feet high, garnished with two oblong entire leaves at every joint; above which the flowers come out in whorls surrounding the stalks, and under each whorl there are six sharp spines, which are as long as the empalement of the flowers. These joints are about three inches distance; the flowers are blue, and have more of the form of the labiated flowers, than any of the other species. I received this from Panama.

The second sort has been long in the curious gardens in Holland, but has not been many years in this country. This sends out many slender stems from the root, which rise eight or nine feet high, garnished with oval pointed leaves, two growing opposite at each joint, which are attended by four long spines standing cross-ways. This plant hath not as yet flowered in England, though there are large plants of it in the Chelsea garden.

The third sort hath shrubby stalks which rise five or six feet high, garnished with roundish entire leaves placed opposite, under which are placed strong spines; the flowers are produced in whorls toward the upper part of the stalk; these are succeeded by short seed-vessels, containing three or four flat seeds. This grows naturally in Jamaica.

The fourth sort grows naturally in the warm parts of America. The stalks of this are smooth; they rise

four feet high, are garnished with two oval indented leaves standing opposite; the flowers are scarlet, and are placed in whorls at the joints of the stalks; these appear in July, August, and September, and are succeeded by short pods inclosing flat seeds.

The roots of the first sort will continue three or four years, but after the second year, the plants grow too rambling, and the lower part of the branches are naked, so are not so sightly as the young plants; therefore a succession of these should be raised, and the old ones turned out. They are propagated by seeds, which will sow themselves in the pots which are near them in the stove, when the plants are once obtained; but where the seeds are received from abroad, they must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, and plunged into a hot-bed of tanners bark, where they must constantly remain, and managed in the same manner as other tender exotics from the same countries; giving them water frequently in summer, and letting the fresh air to them every day in warm weather, but in winter they should have less water and be kept warm. They flower from June to November, and their seeds ripen soon after.

The second sort hath flexible perennial stalks, which if cut off during the summer months, and made into lengths of six or eight inches, and planted in pots, plunging them into a hot-bed, and duly watered and shaded from the sun, will soon put out roots, so may be planted each in a small pot, and plunged into the tan-bed in the stove; for although this sort may be kept in a dry stove through the winter, yet the plants will not grow near so fast, nor will their leaves be so large as those which are plunged into bark. By this method the plants may be propagated in plenty, but as they rarely produce flowers in England, so two or three plants will be sufficient to maintain the species.

The third and fourth sorts will produce seeds in England, provided the plants are kept in the tan-bed in the stove, so these may be propagated by seeds, which should be sown in the hot-bed, and the plants afterward treated in the same manner as the first sort.

BAROMETER [from *βάρος*, a weight, and *μέτρον*, a measure,] is an instrument or machine for measuring the weight of the atmosphere, or the minute variation of the weight or pressure of the incumbent air, in order to determine the changes of weather.

This machine is founded on the Torricellian experiment, so called, from the inventor Torricellius.

1. It consists of a long tube of glass, hermetically sealed at one end; and being filled with quicksilver, is inverted so as to have one end of it immersed in a basin of stagnant quicksilver, and the other hermetically sealed, which is exposed to the pressure of the outward air; out of which open end (after such immersion) the quicksilver in the tube being suffered to run as much as it will into the stagnant quicksilver, in which that mouth or open end is immersed, there is wont to remain a cylinder of quicksilver suspended in the tube, about twenty-eight, twenty-nine, or thirty inches high, measuring from the surface of the stagnant quicksilver perpendicularly; but more or less within such limits, according as the weight or pressure of the air incumbent on the external stagnant quicksilver exposed to it, is greater or lesser, leaving the upper part of the tube void, or at least empty of common air.

The phenomena of the barometer are various, and the causes assigned for them, by several authors, as various; nor is the use of it in predicting the weather, yet perfectly ascertained.

The greatest height the mercury has been known to stand at in London, is thirty inches three-eighths, and its least, twenty-eight inches: and though, as Mr. Boyle observes, the phenomena of the barometer are so very precarious, that it is very difficult to form any general rules about the rise and fall thereof, since

in that which seems to hold most universally, viz. that when the high winds blow, the mercury is the lower, they sometimes fail, yet the following observations have been made by several authors.

Dr. Halley observes, that in calm weather, when the air is inclined to rain, the mercury is continually low; in serene good settled weather, high.

That on great winds, though unaccompanied with rain, the mercury is lowest of all, with regard to the point of the compass the wind blows on; that, *ceteris paribus*, the greatest heights of the mercury are on easterly and north-easterly winds; that after great storms of wind, when the mercury has been low, it rises again very fast.

That in calm frosty weather it stands high.

That the more northerly places find greater alterations than the more southern; and that within the tropics, and near them, there is little or no variation of the mercury at all.

Dr. Beal observes, that, *ceteris paribus*, the mercury is higher in cold weather than in warm, and usually higher in morning and evening than at mid-day.

That the mercury is higher in settled and fair weather, than either a little before, or after, or in the rain; and that it generally descends lower after rain, than it was before it; if it chance to rise higher after rain, it is generally followed by a settled serenity.

That there are frequently great changes in the air, without any perceptible alterations in the barometer.

As to the predictions from the barometer, Dr. Halley has found,

That the rising of the mercury forebodes fair weather after foul, and an easterly or north-easterly wind.

That the falling of the mercury portends southerly or westerly winds, with rains, or stormy winds, or both.

That in a storm the mercury beginning to rise, is a pretty sure sign that it begins to abate.

Mr. Patrick observes, that the falling of the mercury in hot weather presages thunder; that when foul weather happens after the fall of the mercury, it seldom holds long; and the same is observed, if fair weather succeeds presently after its rise.

Hence Mr. Pointer conceives, that the principal cause of the rise and fall of the mercury, is from the variable winds which are found in the temperate zones, and whose great inconstancy here in England is most notorious.

A second cause he takes to be, the uncertain exhalation and perspiration of the vapours lodging in the air, whereby it comes to be at one time much more crowded than at another, and consequently heavier; but this latter, in a great measure, depends upon the former.

And from these principles, he endeavours to explain the several phenomena of the barometer.

1. The mercury's being low, inclines it to rain; because the air being light, the vapours are no longer supported thereby, being become specifically heavier than the medium wherein they are floated; so that they descend towards the earth, and in their fall, meeting with other aqueous particles, they incorporate together, and form little drops of rain; but the mercury's being at one time lower than another, is the effect of two contrary winds blowing from the place where the barometer stands, whereby the air of that place is carried both ways from it, and consequently the incumbent cylinder of air is diminished, and accordingly the mercury sinks. As for instance, if in the German ocean it should blow a gale of westerly wind, and at the same time an easterly wind in the Irish sea; or if in France it should blow a northerly wind, and in Scotland a southerly, it must be granted, that that part of the atmosphere impendent over England, would thereby be exhausted and attenuated, and the mercury would subside; and the vapours which before floated in those parts of the air, of equal gravity with themselves, would sink to the earth.

2. The greater height of the barometer is occasioned

by two contrary winds blowing towards the place of observation, whereby the air of other places is brought thither and accumulated; so that the incumbent cylinder of air being increased both in height and weight, the mercury pressed thereby must needs rise and stand high, as long as the winds continue so to blow; and then the air being specifically heavier, the vapours are better kept suspended, so that they have no inclination to precipitate and fall down in drops, which is the reason of the serene good weather, which attends the greater heights of the mercury.

3. The mercury sinks the lowest of all by the very rapid motion of the air in storms of winds.

For the tract of the region of the earth's surface, wherein these winds rage, not extending all round the globe; that stagnant air which is left behind, as likewise that on the sides, cannot come in so fast as to supply the evacuation made by so swift a current; so that the air must necessarily be attenuated when and where the said winds continue to blow, and that more or less, according to their violence: add to which, that the horizontal motion of the air being so quick as it is, may, in all probability, take off some part of the perpendicular pressure thereof; and the great agitation of its particles is the reason why the vapours are dissipated, and do not condense into drops, so as to form rain, otherwise the natural consequence of the air's rarefaction.

4. The mercury stands the highest upon an easterly or north-easterly wind; because, in the great Atlantic ocean, on this side the thirty-fifth degree of north latitude, the westerly and south-westerly winds blow almost always trade: so that whenever here the winds come up at east and north-east, it is sure to be checked by a contrary gale as soon as it reaches the ocean; wherefore, according to what is made out in the second remark, the air must needs be heaped over this island, and consequently, the mercury must stand high, as often as these winds blow.

5. In calm frosty weather, the mercury generally stands high, because, as he conceives, it seldom freezes but when the winds come out of the northern or north-eastern quarters, or at least, unless those winds blow at no great distance off.

For the northern parts of Germany, Denmark, Sweden, Norway, and all that tract, from whence north-eastern winds come, are subject to almost continual frost all the winter, and thereby the lower air is very much condensed, and in that state is brought hitherward by those winds; and, being accumulated by the opposition of the westerly wind blowing in the ocean, the mercury must needs be pressed to a more ordinary height; and, as a concurring cause, the shrinking of the lower parts of the air into lesser room by cold, must needs cause a descent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an equilibrium.

6. After great storms of winds, when the mercury has been very low, it generally rises again very fast: he says, he once observed it to rise an inch and a half in less than six hours, after a long continued storm of south-west wind.

The reason is, because the air being very much rarefied by the great evacuations that such continued storms make thereof, the neighbouring air runs in more swiftly, to bring it to an equilibrium, as we see water runs the faster for having a greater declivity.

7. The variations are greater in the more northerly places, as at Stockholm greater than at Paris [compared by Mr. Paschal;] because the more northerly parts have usually greater storms of wind than the more southerly, whereby the mercury should sink lower in that extreme; and then the northerly winds bringing the condensed and ponderous air from the neighbourhood of the pole, and that again being checked by a southerly wind, at no great distance, and so heaped up, must of necessity, make the mercury in such case stand higher in the other extreme.

8. This remark, that there is little or no variation near the equinoctial, does, above all others, confirm the

the hypothesis of the variable winds being the cause of these variations of the height of the mercury; for in the places above-named, there is always an easy gale of wind, blowing nearly upon the same point, viz. E. N. E. at Barbadoes, and E. S. E. at St. Helena; so that there being no contrary currents of the air to exhaust or accumulate it, the atmosphere continues much in the same state.

Mr. Patrick gives us the following rules and observations for the rising and falling of the mercury, in order to foreknow the weather by the barometer.

1. It has been observed, that the motion of the mercury does not exceed three inches in its rising or falling in the barometer of the common form.
2. That its least alterations are to be minded, in order to the right finding of the weather by it.
3. The rising of the mercury presages in general fair weather, and its falling, foul, as rain, snow, high winds, and storms.
4. In very hot weather, the falling of the mercury foretells thunder.
5. In winter, the rising of the mercury presages frost; and in frosty weather, if the mercury falls three or four degrees, there will certainly follow a thaw; but if the mercury rises in a continued frost, it will certainly snow.
6. When foul weather happens soon after the falling of the mercury, you may expect but little of it; and you may judge the same, when the weather proves fair shortly after the mercury has risen.
7. When the mercury rises much and high in foul weather, and continues so for two or three days before the foul weather is over, you may expect a continuance of fair weather to follow.
8. When the mercury falls much and low in fair weather, and continues so for two or three days before the rain comes, then you may expect a great deal of wet, and probably high winds.
9. The unsettled motion of the mercury denotes uncertain and changeable weather.
10. You are not so strictly to mind the words engraven on the plates, though for the most part they will agree with them, as the rising and falling of the mercury; for if it stands at much rain, and rises up to changeable, it presages fair weather, although not to continue so long as it would have done, if the mercury were higher, and so on the contrary.

These rules and observations are sufficient to instruct persons who are unacquainted with this instrument, how to make their observations; and with constantly remarking what alterations happen in the weather on the variations of the mercury, a person may nearly predict the great alterations of the weather a day or two before they happen, which is frequently of great use to the gardener and farmer, but particularly to the latter, who may begin to mow his grass when he finds there is a prospect of fair weather, or postpone it a few days until he foresees a likelihood of such. The same also may be of great moment in reaping his corn, as also in sowing his grain, and most of his other business. Therefore the use of this instrument should be more generally known by the practical farmer and gardener.

BARTRAMIA. See TRIUMFETTA.

BASELLA, or climbing Nightshade from Malabar.

The CHARACTERS are,

The flower hath no empalement; it is shaped like a pitcher, fleshy at the base and swelling, but closed toward the brim, where it is divided into six parts, two of which are larger than the others. It hath five awl-shaped stamina, which are equal, fastened to the petal, crowned with roundish summits. The globular germen, which is situated in the center, supports three slender styles, crowned by oblong stigma. The petal of the flower remains, and incloses a roundish fleshy berry, including one round seed.

This genus of plants is ranged in the third section of Linnaeus's fifth class, entitled Pentandria Trigynia, the flower having five stamina and three styles.

The SPECIES are,

1. BASELLA (*Rubra*) foliis planis, pedunculis simplici-

bus. Lin. Sp. 390. *Basella with plain leaves and simple foot-stalks.* Cuscuta foliis subcordatis. Hort. Cliff. 39. *Climbing Nightshade.*

2. BASELLA (*Alba*) foliis ovatis undatis, pedunculis simplicibus folio-longioribus. Lin. Sp. 390. *Basella with oval waved leaves, and foot-stalks longer than the leaf.* Basella Sinica, foliis & caulibus viridibus minus succulentibus fructu minore. Just.

The first sort has thick, strong, succulent stalks and leaves, which are of a deep purple colour. The plant requires to be supported, for it will climb to the height of eight or ten feet, when the plants are kept in a stove or glass-case, and produce a great number of side branches: but if they are exposed to the open air, they will not grow so large, nor will they perfect their seeds, except it be in very warm seasons; when they are placed in the bark-stove, they will often live through the winter, and produce great quantities of flowers and seeds. The flowers of this plant have no great beauty, but the plant is preserved for the odd appearance of the stalks and leaves.

The seeds of the second sort I received from Dr. Jussieu of Paris, from whence I have obtained two varieties; one of which hath purple stalks and leaves, and the other hath leaves variegated with white; but both of them retain their small stalks, and oblong flaccid leaves, smaller flowers and fruit, in which they essentially differ from the first.

These plants are propagated by seeds, which should be sown in a hot-bed in the spring; and when the plants are fit to remove, they should be each planted into a separate pot filled with rich earth, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotics. They may also be propagated by cuttings, which should be laid to dry a day or two after they are taken from the plants, before they are planted, that the wound may heal, otherwise they will rot. These cuttings must be planted into pots filled with light fresh earth, and plunged into a moderate hot-bed of tanners bark, where they will take root in a fortnight or three weeks time, when they should be treated in the same manner as the seedling plants. But as these rise so easily from seeds, it is seldom they are propagated any other way, because they are plants of short duration. These flower from June to autumn, and the seeds ripen in September and December.

These plants will climb to a considerable height, and send forth a great number of branches, so that they should have a place near the back of the stove, where they may be trained up to a trellise, or fastened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them, and be very injurious to the other plants; whereas, when they are regularly trained to a trellise, they will have a good effect in adding to the variety.

From the berries of the first sort, I have seen a beautiful colour drawn, but when used for painting, did not continue very long, but changed to a pale colour; though I believe there might be a method invented, whereby this beautiful colour might be fixed, so as to become very useful; for I have been assured, that the juice of these berries has been used for staining of calicoes in India.

BASILICUM, or BASIL. See OCYRUM.

BASONS or fountains, &c. which serve either for the ornament or use of gardens, are made in divers forms, some round, some oblong or oval, others square, octangular, &c. but their most common form is circular; and, if the ground will permit, the larger they are the better; and when they exceed in size, they are called pieces of water, canals, fish ponds, pools, and reservoirs.

In making these, care ought to be taken to avoid both the extremes, and not to make them either too big or too little, that a water work may not take up the best part of a small spot of ground; nor to make too little a basin in a large spot. This must depend entirely on the judgment of the designer of the garden.

Some would have the size of a bason to be proportioned to the Jet d' Eau, that the water thrown up in the air, may not, by being blown by the air, be carried beyond the edge of the bason, but all fall down without wetting the walk.

As to the depth of basons it is usually from two to three feet, this depth being sufficient to secure the bottom of the basons from frost, and to dip watering pots.

But if they are to serve for reservoirs, or to keep fish in, then they may be made four or five feet deep, which will both hold water enough, and be deep enough for the fish to breed in, and also to bear a boat.

Deeper than this they need not be, and if they were deeper, they would be dangerous as to the drowning of persons who might chance to fall in.

In making basons, great care ought to be taken in making them at first; for the water always naturally endeavouring to run away, and by its weight and pressure in a bason, making its way out at the least cranny, it will grow constantly bigger and bigger; so that if it be not well made at first, it will be very difficult to repair it.

Basons are made either with clay, cement, or lead; they are most usually made of clay; in making such, at the marking out the dimensions, the diameter ought to be four feet bigger on each side, yet the bason will not be the wider, for it will be taken up with the walls on each side; and the clay-work, which is to fill the space between; the bason must also be dug two feet deeper than the depth of the water is designed to be, because it is to be laid over eighteen inches thick with clay, and six inches with gravel and paving.

The clay ought to be well wrought with the hands and water, and when it is spread, should be trodden in with the naked feet, that the water of the bason may not dilute through it, and the roots of any trees that may grow near, may not penetrate into the outward wall, which may be made of shards, rubble, or flints, with mortar made of the natural earth, and is called the ground wall, because it is only made to resist the pressure of the ground about it. The inward wall ought to be made with good rubble stones that will not scale and come off in flashes in the water, or else of flints and stones from the hills, which will make durable work, but will not look so neat as the pointed rubble; and there ought to be laid here and there stones, the thickness of the wall, to render it the more substantial.

The method of making basons of cement is as follows: after you have marked out the dimensions of the bason, as before, if you enlarge it one foot nine inches, it will be sufficient, and the same depth deeper at the bottom will be enough.

This being done, you must begin to back up and raise against the ground; cut perpendicularly a wall of masonry a foot thick, which must go to the bottom, and should be built with shards and rubble stones laid in mortar of lime and sand.

When the wall is finished round the circumference, then the bottom is to be wrought a foot thick with the same materials; and the solid work or lining of cement is to be backed up against the walls nine inches thick, including the plastering and inward surface. This solid ought to be made of small flints, laid in beds of mortar made of lime and cement.

When this solid is eight inches thick, it ought to be plastered over the whole surface of the bottom with cement well sifted before it be tempered with lime; and with this it should be wrought over smooth with the trowel.

The proportion of this cement should be two thirds of cement or powdered tile to one third of lime.

This cement has the property to harden so under water, that it will be as hard as stone or marble, and the body will be so solid as never to decay.

After the finishing of the bason, the plastering should be for four or five days successively anointed over with

oil, or bullock's blood, to prevent it from cracking or flaking; this being done, the water should be let into the bason as soon as may be.

Those basons which are made of lead, are to be thus wrought; the outlines ought to be enlarged one foot of a side, and digged half a foot deeper than the bason is to be.

The wall must be made a foot thick, that it may be able to bear up against the earth lying against it; but the bottom will not require to be more than half a foot thick.

These walls must be built in rubble laid in mortar all of plaster, because the lime will eat the lead, and then the lead must be laid on the walls and bottom, and be seamed with solder.

But basons of lead are not much in use, because of their great charge in making, and the danger of the lead being stolen.

Great care ought to be taken to keep the upper edge and superficies of a bason upon a level, that the water may cover all the walls equally.

As to the waste pipes of basons, whether at the bottom or superficies, they ought not to be made too small, lest they should be choked, notwithstanding the cawls that are drawn before them.

When this waste water is only to be lost in sinks and common sewers, it is carried away in drains or earthen pipes; but when it serves to play the basons that lie below it, it must pass through leaden pipes.

These basons are now pretty generally rejected by persons of good taste, as being no ways ornamental; therefore where there is a necessity to make reservoirs for water for the use of gardens, they are commonly dug in the lowest part of gardens, or where the spot is most convenient for receiving the water, which may run from the adjacent grounds in hard rains; these ponds should have their sides made very easy, for, if they are too upright, the earth frequently breaks down by the water washing, and making it hollow below; the sides and bottoms of these ponds should be laid nine or ten inches thick with well wrought clay; and, as the clay is finished, it should be well covered to prevent the sun and wind from cracking it before the water is let in. The figures of these ponds should not be regular, for the shape of the hollow, where they are made, should be followed, which will save expence, and have a better appearance.

B A S T E R I A. Nov. Gen. All-spice.

As this plant had no proper title given to it, I have given it this in honour of my worthy friend Dr. Job Balter, F. R. S. of Zurick Zee, in Holland, who is a gentleman well skilled in botany, and has a fine garden stored with rare plants, of which he is very communicative to his friends, as I have many years experienced.

The CHARACTERS are,

The empalement of the flower is short, of one leaf, and cut into five narrow segments at the top. It hath a double series of narrow petals, which spread open, and turn inward at their extremity. Under the receptacle is situated an oval germen, having no style, but five stigma resting upon it, and is surrounded by many short stamina, crowned by obtuse summits. The germen afterward becomes a roundish fruit, compressed at both ends, having cells, containing oblong seeds.

We have but one SPECIES of this genus at present in England, which is,

BASTERIA foliis ovatis oppositis, floribus lateralibus caule fruticoso ramoso. Basteria with oval leaves placed opposite, flowers coming from the sides of the stalks, and a branching shrubby stalk. Frutex Corni foliis conjugatis floribus Anemones stellatæ, petalis crassis rigidis colore sordide rubente, cortice Aromatico. Catelb. Hist. Carol. Vol. I. p. 46. commonly called in Carolina All-spice.

This shrub grows naturally in America. Mr. Catelby, who first introduced it into the English gardens, procured it from the continent, some hundred miles on the back of Charles Town, in Carolina.

It seldom rises more than four feet high in this country, dividing into many slender branches near the ground, which are garnished with two oval leaves placed opposite at every joint, which are entire; these have short foot-stalks; the flowers grow single at the extremity of the foot-stalk, which comes out from the wings of the leaves; they have two series of narrow thick petals, which spread open, and turn inward at the top, like those of the Starry Anemone, or the Virgin's Bower: these are of a sullen purple colour, and have a disagreeable scent; they appear in May. The embryo sits beneath the flower, and supports five stigma; this afterward appears to have five cells, but it never comes to perfection in this country, therefore I can only give a description of it from an imperfect rudiment, which a few years past, was fairer than any I had before seen. The bark of this shrub is brown, and has a very strong aromatic scent; from whence the inhabitants of Carolina gave it the title of All-spice, by which it is generally known in the nurseries near London.

This shrub will thrive in the open air in England, if it is planted in a warm situation and a dry soil. It is propagated by laying down the young branches, which will take root in one year, and may then be taken from the mother plant, and planted where they are designed to remain, for they do not bear transplanting well, after they are grown to any size. When the layers are transplanted, the surface of the ground should be covered with mulch, to prevent the drying winds from penetrating the ground to their roots; and if the season proves dry, they must be watered once a week, but should not have too much wet, for that will rot their tender fibres.

The best time for laying down the branches, is in the autumn, but they should not be transplanted till the spring twelve months after, for the spring is the safest time to remove these plants. After the branches are laid down, there should be some old tanners bark laid upon the surface of the ground, to keep out the frost, which should also be done every winter, while the plants are young, which will prevent the frost from penetrating to their root, and thereby secure them.

This plant was very scarce in England, till within a few years past, that many of them have been brought from Carolina, where they have been greatly increased in the gardens near Charles Town.

Dr. Kempfer has given a figure and description of a plant, in his *Amœnitates Exoticarum*, which seems to be of this genus; but he mentions the fruit to be composed of eight cells; whereas, so far as I have been able to examine this, it appears to have but five; however, the flower and general structure of the plant, agrees very well with this, but I suppose it to be a distinct species, the leaves of this being much longer, and the flowers stand upon naked foot-stalks; whereas those of our sort have commonly two small leaves, which are narrower, and more pointed than those upon the branches: but I find Dr. Linnæus and Monsieur Du Hamel, both suppose they are the same plant.

After I had given a figure of this plant, in plate LX. of my *Figures of Plants*, I received Monsieur Du Hamel's book of the trees and shrubs, which will grow in the open air about Paris, in which he has given a bad figure of this plant, under the title of *Butneria*; but as my plate was first published, and I was not apprised of his title, I have continued my title to it; not from any attachment to it, as being my own, but rather to avoid confusion, which must attend the frequent alteration of the names of plants, which is too much in fashion at present.

BAUHINIA, Mountain Ebony, *vulg.* This plant was so named by father Plumier, in honour of the two famous botanists, John and Caspar Bauhin.

The CHARACTERS are,

The empalement of the flower is permanent, tubulous, of one leaf, and cut into five parts at the top; the flower is composed of five petals, which in some species are spect-

shaped; waved and reflexed, but in others roundish and concave: it hath ten stamina, which are of unequal lengths; some of these are crowned by oval summits, but others have none. The oblong germen sits upon the foot-stalk, supporting a slender declining style, which turns upward at the point, crowned by an obtuse stigma; the germen afterward becomes a long taper pod, inclosing a row of roundish compressed seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, entitled *Decandria Monogynia*, the flower having ten stamina and one style.

The SPECIES are,

1. **BAUHINIA** (*Aculeata*) caule aculeato. Hort. Cliff. 156. *Baubinia with a prickly stalk.* *Bauhinia aculeata folio rotundo emarginato.* Plum. Nov. Gen. 23.
2. **BAUHINIA** (*Tomentosa*) foliis cordatis, lobis semiorbiculatis tomentosis. Lin. Sp. 536. *Bauhinia with heart-shaped leaves, and semiorbicular woolly lobes.* *Bauhinia flore luteo spicato folio subrotundo bicorni.* Hoult.

The first sort grows plentifully in Jamaica, and the other sugar islands in America, where it rises to the height of sixteen or eighteen feet, with a crooked stem, and divides into many irregular branches, armed with short strong spines, garnished with compound winged leaves, each having two or three pair of lobes, ending with an odd one, which are oblique, blunt, and indented at the top. The stalks are terminated by several long spikes of yellow flowers, which are succeeded by bordered pods, about three inches long, which contain two or three swelling seeds. These pods are glutinous, and have a strong balsamic scent, as have also the leaves when bruised. It is called in America, the Indian Savin-tree, from its strong odour, somewhat resembling the common Savin.

The second sort was sent me from Campeachy, in 1730, by the late Dr. Houston, where he found it growing naturally. This rises to the height of twelve or fourteen feet, with a smooth stem, dividing into many branches, garnished with heart-shaped leaves, having two smooth-pointed lobes; the extremity of every branch is terminated by a long spike of yellow flowers, so that when these trees are in flower, they make

B A U

make a fine appearance. The pods are swelling, and about five inches long, each containing five or six roundish compressed seeds.

The third sort grows naturally in both Indies, where it rises with several pretty strong, upright, smooth stems, sending out many slender branches, garnished with oval leaves, deeply divided into two lobes. The leaves come out without order, and have long foot-stalks, but are much thinner than those of the species before-mentioned. The flowers come out at the extremity of the branches, three or four in a loose bunch; the petals are red, or striped with white, others are plain upon the same branch; the stamina and style are white, and stand out beyond the petals. These flowers are succeeded by long flat pods of a dark brown colour, each containing five or six roundish compressed seeds. The wood of this tree is very hard, and veined with black, from whence the inhabitants of America call it Mountain Ebony.

The fourth sort grows naturally at Campeachy, from whence I received the seeds. This rises to the height of twenty feet, with a smooth stem, dividing into many small branches, garnished with oblong heart-shaped leaves, having two pointed parallel lobes, which have each three longitudinal veins. The leaves are placed alternately on the branches, which are terminated by loose bunches of white flowers; these are succeeded by very long narrow compressed pods, which have eight or ten compressed roundish seeds in each.

The fifth sort was sent me from Carthagen, in New Spain, where it grows in plenty. This seldom rises more than ten feet high, dividing into many irregular branches, armed with short crooked spines; the leaves grow alternate, are heart-shaped, and have two roundish lobes; they are woolly on their under side, and have short foot-stalks. The flowers grow at the extremity of the branches, two or three together; these are large, and of a dirty white colour, and are succeeded by short flat pods, each containing two or three seeds.

The sixth sort grows naturally at La Vera Cruz. This rises to the height of twenty-five, or thirty feet, with many irregular stems, which divide into many slender branches; garnished with heart-shaped leaves, having two roundish lobes. The flowers come out in loose spikes at every joint from the wings of the leaves, with naked foot-stalks, and are of a dirty white colour, and are succeeded by oblong compressed pods, which are broadest at their extremity, where they are rounded, each containing three or four compressed seeds.

The seventh sort grows naturally at Carthagen, in New Spain. This rises twenty feet high, with a strong upright stem, which sends out many branches toward the top; armed with spines growing by pairs, which are strong and crooked. The leaves are heart-shaped and grow alternately, having two rounded lobes. The flowers are large and white, coming out thinly at the ends of the branches. The petals of these are near two inches long, and spread open wide; the stamina and style are nearly of the same length. The flowers are succeeded by long flat pods, which are narrow, each containing five or six seeds.

The eighth sort grows naturally in both Indies. This rises with a strong stem, upward of twenty feet high, dividing into many strong branches, garnished with heart-shaped leaves, having obtuse lobes which close together. The flowers are large and grow in loose panicles; at the extremity of the branches, of a purplish red colour, marked with white, and have a yellow bottom. These have a very agreeable scent. The flowers are succeeded by compressed pods, about six inches long, and three quarters of an inch broad, containing three or four compressed seeds in each.

The ninth sort grows naturally in both Indies, where it rises with many slender stalks, which put out tendrils, and fasten themselves to the neighbouring trees, whereby they rise to a great height; the leaves come out alternately, are heart-shaped, standing upon long

B E L

foot-stalks; these are six inches long, and three inches and a half broad in the middle, and are deeply cut into two pointed lobes, each having three prominent ribs running longitudinally. This hath not produced flowers in England, nor had I any account of them with the seeds, which were sent me from Campeachy.

The tenth sort grows naturally in great plenty on the north side of the island of Jamaica. This is a low shrub, seldom rising more than five or six feet high, but divides into several branches, garnished with oval leaves, divided into two lobes, which spread from each other. The flowers grow in loose panicles at the end of the branches, which are white, and have a very agreeable scent. These appear the greatest part of summer, so is one of the great beauties of the hot-house. The flowers are succeeded by taper pods, about four inches long, each containing four or five roundish compressed seeds, of a dark colour.

All these plants are natives of the warm countries, so will not thrive in England, unless they are kept in a warm stove. They are propagated by seeds, which must be procured from the countries where they grow naturally, for they do not perfect their seeds in England.

The last sort has several times produced pods in the Chelsea garden, but they have never come to maturity. The seeds should be brought over in their pods, which will preserve them good. These must be sown in pots filled with light fresh earth, and plunged into a moderate hot-bed of tanners-bark; if the seeds are good, the plants will come up in about six weeks, and in a month after, will be fit to transplant, when they should be carefully shaken out of the seed pot, so as not to tear off the roots, and each planted into a separate small pot filled with light loamy earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root, after which they should have fresh air admitted to them every day in warm weather. In the autumn they must be placed in the bark-stove, and treated in the same way as other tender exotics, giving them but little water in winter. As these plants frequently flower, they are worthy of a place in the stove.

BELLIS [is so called Bellus, Lat. pretty, handsome, &c.] the Daisy.

The CHARACTERS are,

It hath a radiated discous flower, composed of many hermaphrodite florets in the disk, and female florets in the rays; included in a common empalement, with a double series of small leaves of equal length. The hermaphrodite florets in the disk, are funnel-shaped, and cut into five parts at the brim; the female florets are tongue-shaped, and make the border; these have no stamina, but an oval germen supporting a slender style, crowned by two spreading stigma; the hermaphrodite florets have an oval germen, supporting a simple style, crowned by a bordered stigma. This is attended by five short stamina, crowned by tubular cylindrical summits. The germen afterward becomes a single naked seed placed vertically.

This

B E L

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers being composed of female and hermaphrodite florets, included in a common empalement.

The SPECIES are,

1. **BELLIS** (*Perennis*) scapo nudo unifloro: Hort. Cliff. 418. *Daisy with a naked stalk, having one flower.* Bellis sylvestris minor. C. B. P. 267. *Smaller wild Daisy.*
2. **BELLIS** (*Annua*) caule subfolioso. Lin. Sp. Plant. 887. *Daisy with leaves on the lower part of the stalk.* Bellis minor pratensis caule folioso. Bocc. Mus. 2. p. 96.

3. **BELLIS** (*Hortensis*) hortensis flore pleno majore. C. B. P. 261. *Garden Daisy with a larger double flower.*

The first sort is the common Daisy, which grows naturally in pasture land in most parts of Europe, and is often a troublesome weed in the grass of gardens, so is never cultivated.

The second sort is a low annual plant, which grows naturally on the Alps, and the hilly parts of Italy. This seldom rises more than three inches high, with an upright stalk, which is garnished with leaves on the lower part; but the upper part is naked, supporting a single flower like that of the common Daisy, but smaller. This is preserved in some botanic gardens for the sake of variety; it was sent me from Verona, near which place it grows wild.

The Garden Daisy is generally supposed to be only a variety of the wild sort, which was first obtained by culture. This may probably be true, but there has not been any instance of late years of the wild sort having been altered by culture; for I have kept the wild sort in the garden upward of forty years, and have constantly parted the roots, and raised many plants from seeds, but they have constantly remained the same; nor have I ever observed the Garden Daisy to degenerate to the wild sort, where they have been some years neglected, tho' they have altered greatly with regard to the size and beauty of their flowers. I have also observed the several varieties of the Garden Daisy vary from one to the other, therefore I shall not consider them as distinct species, but shall only mention the varieties, which are cultivated in the gardens.

1. The red and white Garden Daisy, with double flowers.
2. The double variegated Garden Daisy.
3. The Childing, or Hen and Chicken Daisy.
4. The Cockscorn Daisy with red and white flowers.

The Garden Daisies flower in April and May, when they make a pretty variety, being intermixed with plants of the same growth; they should be planted in a shady border, and a loamy soil without dung, in which they may be preserved without varying, provided the roots are transplanted and parted every autumn; which is all the culture they require, except the keeping them clear from weeds.

These were formerly planted for edgings to borders, but they are very unfit for this purpose; because where they are fully exposed to the sun, they frequently die in large patches, whereby the edgings become bald in many places.

BELLIS MAJOR. See CHRYSANTHEMUM.

BELLONIA.

This plant was so named by Father Plumier, in honour of the famous Petrus Bellonius, who has left many valuable tracts on natural history, &c.

The CHARACTERS are,

It hath a permanent empalement which is of one leaf, cut into five parts at the top; the flower is wheel-shaped, of one leaf, with a short tube, but spread open above, and cut into five obtuse segments. It hath five awl-shaped stamina, which are short, and crowned by short erect summits, which close together. The germen is situated under the receptacle of the flower, supporting an awl-shaped style, which is longer than the stamina, and crowned by an acute stigma. The germen afterward becomes an oval turbinated seed-vessel, ending in a point, having one cell filled with small round seeds.

B E R

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

We have but one SPECIES of this genus, viz.

BELLONIA. Lin. Sp. Plant. 172. Bellonia frutescens, folio melissæ asperæ. Plum. Nov. Gen. 19.

This plant is very common in several of the warm islands in America, from whence I have received the seeds.

It hath a ligneous stalk, which rises ten or twelve feet high, sending out many lateral branches, garnished with oval rough leaves placed opposite; the flowers come out from the wings of the leaves, in loose panicles, which are of the wheel shape, of one leaf, divided into five parts; these are succeeded by oval capsules, ending in a point, which are full of small round seeds.

It is propagated by seeds, which should be sown early in the spring, in a pot filled with light fresh earth, and plunged into a hot-bed of tanners barks, observing to water it frequently, as the earth appears dry; but you must be careful not to wash the seeds out of the ground. When the plants are come up half an inch high, they should be carefully transplanted into pots filled with light fresh earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root; after which timethey should have air admitted to them every day, when the weather is warm; they must also be frequently watered. When the plants have filled these pots with their roots, they should be carefully shaken out of them, and their roots trimmed, and put into larger pots filled with light fresh earth, and plunged into the hot-bed again. In warm weather they should have free air admitted to them every day; but in autumn they must be plunged into the bark-stove, and treated in the same manner as other tender exotic plants. The second year these plants will sometimes flower, but they rarely produce good seeds in this climate; however, they may be propagated by cuttings in the summer months, provided they are planted in light earth on a moderate hot-bed, and carefully watered and shaded until they have taken root. These plants must be constantly kept in the stove, and should have a large share of free air in warm weather; but if they are set abroad, they will not thrive in this climate.

BELVEDERE. See CHENOPodium.

BENZON, the Benjamin-tree. See LAURUS.

BERBERIS, the Barberry, or Pimperidge-bush.

The CHARACTERS are,

It hath a coloured empalement, which spreads open, composed of six concave leaves, three of which are alternately larger than the other; the flower is of six leaves, which are roundish, concave, and little larger than the empalement; there are two coloured nettarii, fastened to the base of each petal, and six obtuse, compressed, erect stamina, with two summits fastened on each side their apex. The germen is cylindrical, the length of the stamina, having no style, but crowned by an orbicular stigma broader than the germen, having a sharp border: the germen afterward becomes an obtuse, cylindrical, umbilicated berry, having a puncture, and one cell inclusing two cylindrical seeds.

This genus is ranged in Linnæus's first section of his sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. **BERBERIS** (*Vulgaris*) pedunculis racemosis. Mat. Med. 290. *Barberry with branching foot-stalks.* Berberis dumetorum. C. B. P. 454. *The common Barberry.*
2. **BERBERIS** (*Canadensis*) foliis obversè-ovatis. *Barberry with oval obverse leaves.* Berberis latissimo folio Canadensis. H. R. Par.
3. **BERBERIS** (*Cretica*) pedunculis unifloris. Lin. Sp. Plant. 331. *Barberry with a single flower on each foot-stalk.* Berberis Cretica buxi folio. Tourn. Cor. 42.

The first sort grows naturally in the hedges in many parts of England, but is also cultivated in gardens for its fruit, which is pickled, and used for garnishing dishes. This shrub rises with many stalks from

K k

the

the root, to the height of eight or ten feet, which have a white bark, yellow on the inside; the stalks and branches are armed with sharp thorns, which commonly grow by threes; the leaves are oval, obtuse, and slightly sawed on their edges. The flowers come out from the wings of the leaves, in small ramose bunches, like those of the Currant-bush, which are yellow; these are succeeded by oval fruit, which are first green, but when ripe turn to a fine red colour. The flowers appear in May, and the fruit ripens in September.

There are two or three varieties of this shrub, which have been mentioned as distinct species; one is the *Berberis sine nucleo*. C. B. P. *Barberry without stone*. The second is *Berberis fructu albo*. *Barberry with white fruit*. The third is the *Berberis orientalis* procerior fructu nigro suavissimo. Tourn. Cor. *Taller Eastern Barberry with a black sweet fruit*. The first of these is certainly accidental, because the suckers, taken from those bushes being transplanted, commonly produce fruit with stones; so it is the age of the plant which occasions that variation. The sort with white fruit seldom bears; the leaves of this are of a lighter green colour, and the bark of the stalks are whiter than those of the common, which are the only differences between them, for the fruit is seldom produced here. The third sort appears the same with the common, and only differs in the colour and flavour of the fruit, so is only a variety.

The common sort is generally propagated by suckers, which are put out in great plenty from the root; but these plants are very subject to send out suckers, in greater plenty than those which are propagated by layers; therefore the latter method should be preferred. The best time for laying down the branches is in the autumn, when their leaves begin to fall; the young shoots of the same year are the best for this purpose; these will be well rooted by the next autumn, when they may be taken off, and planted where they are designed to remain. Where this plant is cultivated for its fruit, it should be planted single, (not in hedges, as was the old practice) and the suckers every autumn taken away, and all the gross shoots pruned out: by this method the fruit will be much fairer, and in greater plenty, than upon those which are suffered to grow wild. A few of these shrubs may be allowed to have place in wildernesses, or plantations of shrubs, where they will make a pretty variety, and the fruit will be food for the birds; but they should not be planted in great quantities, near walks which are much frequented, because their flowers emit a very strong disagreeable odour.

The Canada sort was more common in the English gardens, some years past, than at present. The leaves of this are much broader, and shorter than those of the common sort, and the fruit is black when ripe. This may be propagated in the same way as the common sort, and is equally hardy.

The Box-leaved sort is at present very rare in England; and while young, the plants are somewhat tender, so have been killed by severe frost. This never rises more than three or four feet high in England, but sends out many stalks from the root, which are strongly armed with spines at every joint; the leaves are produced without order, and are shaped like those of the narrow-leaved Box-tree; the flowers come out from between the leaves, each upon a slender foot-stalk; but these are not succeeded by fruit in England.

This sort may be propagated by laying down the branches in the same manner as the first; but when the young plants are taken off, they should be planted in pots, and sheltered under a frame in the winter, till they have obtained strength, when they may be turned out of the pots, and planted in a warm situation.

BERMUDIANA. See SISYRINCHIUM.

BERNARDIA. See CROTON.

BESLERIA

This plant was named after Basilius Besler, an apo-

thecary at Nuremberg, who was the author of a book, intitled *Hortus Eystetensis*.

The CHARACTERS are,

The flower is of the personated or lip kind, with an empalement of one leaf, which is erect, and cut into five acute parts at the brim: the flower is of one leaf, and quinquefid; the segments being roundish, the lower being large, and the two upper are less divided; it hath four stamens in the tube of the flower, two of which are longer than the other, crowned by small summits: the oval germen supports an awl-shaped style, crowned by an acute stigma; this afterward becomes an oval berry, with one cell filled with small seeds.

This genus of plants is ranged in the second section of Linnæus's twelfth class, intitled *Didynamia Angiospermia*, the flower having two long and two short stamens, and the seeds being included in a capsule.

The SPECIES are,

1. *BESLERIA (Melittifolia) pedunculis ramosis, foliis ovatis*. Lin. Sp. Plant. 619. *Besleria with branching foot-stalks and oval leaves*. *Besleria Meliffæ* Tragi folio. Plum. Nov. Gen. 29.
2. *BESLERIA (Lutea) pedunculis simplicibus confertis, foliis lanceolatis*. Lin. Sp. Plant. 619. *Besleria with simple foot-stalks growing in clusters, and spear-shaped leaves*. *Besleria virgæ aureæ foliis flore luteo minor*. Plum. Nov. Gen. 29.
3. *BESLERIA (Cristata) pedunculis simplicibus solitariis, involucris pentaphyllis propriis*. Lin. Sp. Plant. 619. *Besleria with simple stalks growing single, and a five-leaved involucre*. *Besleria scandens cristata fructu nigro*. Plum. Nov. Gen. 29.

The first sort hath a smooth woody stalk which is jointed; at each joint are placed two oval nervous leaves opposite, which are crenated on their edges; the flowers come out from the wings of the leaves, upon short branching foot-stalks, each sustaining six or eight flowers, which stand each upon a separate smaller foot-stalk. These are of one leaf, of an anomalous figure, and quinquefid; after the flower is past, the germen becomes an oval soft berry, with one cell filled with small seeds.

The second sort rises with a ligneous stem six or seven feet high, dividing toward the top into many irregular branches, garnished with spear-shaped sawed leaves, which have many transverse veins; the flowers come out at the wings of the leaves, in large clusters, each having a separate foot-stalk: these are small, tubulous, and of a pale yellow colour, and are succeeded by round soft berries, inclosing many small seeds.

The third sort hath a creeping stalk, which sends out roots at every joint, garnished with oval leaves placed opposite, which have many transverse ribs, and are sharply sawed on their edges; from the wings of the leaves come out the foot-stalks of the flowers single, each sustaining one tubulous, irregular, hairy flower, divided at the top into five obtuse parts, with a large five-leaved involucre, deeply sawed on the border: after the flower is past, the germen becomes a hairy placenta, in the center of the empalement, containing many small seeds.

These plants grow naturally in the warm parts of America. The seeds should be sown on a hot-bed early in the spring; and when the plants are come up half an inch high, they should be each transplanted into a small pot filled with light fresh earth, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root; after which time they should have air and water in proportion to the warmth of the season, and the heat of the bed in which they are placed. When the plants have filled these small pots with their roots, they should be shaken out of them, and their roots trimmed, and put into larger pots filled with light fresh earth, and plunged into the hot-bed again; where they should have a large share of air in warm weather, and must be frequently watered. With this management the plants will thrive very well in summer, but

B E T

but in winter they must be removed into the stove, where they must be placed in a temperate warmth, and should be often, but sparingly, watered. The second year these plants will flower, and sometimes they will perfect their seeds in this country; but they must be constantly preserved in the stove, for they will not live in the open air.

B E T A, the Beet.

The CHARACTERS are,

The flower hath a five-leaved concave empalement, which is permanent. It hath no petal, but five awl-shaped stamina, placed opposite to the leaves of the empalement, crowned by roundish summits. The germen is situated below the receptacle, supporting two short erect styles, crowned by pointed stigma. The germen afterward becomes a capsule with one cell, having a single seed, wrapped up in the empalement.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. BETA (*Maritima*) caulibus decumbentibus, foliis triangularibus petiolatis. Beet with declining stalks, and triangular leaves having foot-stalks. Beta sylvestris maritima. C. B. P. 118.
2. BETA (*Hortensis*) foliis radicalibus petiolatis; caulibus sessilibus, spicis lateralibus longissimis. Beet with the lower leaves having foot-stalks; those upon the stalks without, and very long spikes of flowers. Beta alba vel pallescens, quæ cicla officinarum. C. B. P. 118.
3. BETA (*Vulgaris*) caule erecto. Lin. Sp. 322. Common red Beet. Beta rubra radice rapacæa. C. B. P. 118. Red Beet with a Turnep root.

There are several varieties of this genus, some of which are cultivated in the gardens for the kitchen; but as these have been improved by culture, so they must not be deemed distinct species. There are some who have supposed all the species were only seminal variations, but from having cultivated them upward of forty years, I could never observe, that either of the three species here enumerated have altered from one to the other. The only alteration which I have observed in the third species, has been in the colour of the leaves and roots; which will be hereafter mentioned.

The first sort grows naturally on the banks of the sea, and in salt marshes in divers parts of England. This has been supposed by many, to be the same with the second species; but I have brought the seeds from the places where they grow naturally, many times, and have cultivated the plants with care, but could not find any of the plants vary from their parent plants in their characters, so that I can make no doubt of its being a distinct species.

The second sort is cultivated in gardens for its leaves, which are frequently used in soups; the root of this sort seldom grows larger than a man's thumb; the stalks grow erect, and are garnished with oblong spear-shaped leaves, growing close to the stalk; the spikes of flowers come out from the wings of the leaves, which are long; and have narrow leaves placed between the flowers. The lower leaves of the plant are thick and succulent, and their foot-stalks are broad. The varieties of this are, the White Beet, the Green Beet, and the Swiss or Chard Beet. These will vary from one to the other by culture, as I have often experienced, but never alter to the first or third sort.

The third sort hath large, thick, succulent leaves, which are for the most part of a dark red, or purple colour. The roots of this are large, and of a deep red colour, on which their goodness depends; for the larger these roots grow, the tenderer they will be; and the deeper their colour, the more they are esteemed. The varieties of this are, the common Red Beet, the Turnep-rooted Red Beet, the Green-leaved Red Beet, and the Yellow-rooted Beet.

The second sort, which is cultivated in gardens for its leaves, which are used in the kitchen, is commonly sown by itself, and not mixed with other crops.

B E T

This is sown the beginning of March, upon an open spot of ground, not too moist; the seeds should be sown thinly, because the plants require room to spread; for when they are too close, the leaves will be small and full of fibres, so unfit for the purposes designed. When the plants have put out four leaves, the ground should be hoed; as is practised for Carrots, carefully cutting up all the weeds, and also the plants where they are too near each other, leaving them at least four inches asunder: if this is performed in dry weather, all the present weeds will be destroyed; but as young weeds will soon appear, so in three weeks or a month's time, the ground should be a second time hoed over, to cut up the weeds; and thin the plants to a greater distance; for by this time they will be past danger, so should not be left nearer than six inches, if regard is had to the goodness of their leaves: and if it is of the Swiss kind, with broad leaves, the plants must not be nearer than nine or ten inches. If the second hoeing is well performed, and in dry weather, the ground will remain clean a month longer, when it should be hoed over a third time; which, if properly done, will destroy all the weeds; so that after this, the plants will spread and prevent the weeds from growing, therefore will want but little cleaning for a considerable time, and the leaves will soon be fit for use, when the outer large leaves should be first gathered, leaving the small inner leaves to grow larger; so that a small spot of ground will supply a moderate family, and will furnish a new supply of leaves for two years, provided the plants are not permitted to run up to seed, for after that, their leaves will not be good: therefore those who are curious in their herbs, must sow a fresh spot of ground annually, because these plants naturally run up the second year; and although the roots may be continued longer, by cutting off the stalks when they begin to shoot, yet the leaves will not be so large or tender upon these roots, as upon the young plants.

The Red Beet is frequently sown with Carrots, Parsneps, or Onions, by the kitchen gardeners near London, who draw up their Carrots or Onions when they are young; whereby the Beets will have room to grow, when the other crops are gathered; but where the crops are not timely removed from them, it will be a better method to sow them separately. This sort requires a deep light soil, for as their roots run deep in the ground, so in shallow ground they will be short and stringy. The seeds should be sown in March, and must be treated in the same manner as the former sort; but the plants should not be left nearer than a foot distance, or in good land a foot and a half, for the leaves will cover the ground at that distance. The roots will be fit for use in the autumn, and continue good all the winter; but in the spring, when they begin to shoot, they will be hard and stringy. A few roots may be left for seed, or some of the fairest roots transplanted to a sheltered spot of ground, where they may be defended from strong winds, which frequently break down their stalks, if they are not well supported, especially when the seeds are formed; which becoming heavy as it increases in bulk, is apt to weigh down the slender stalks upon which they grow. The seed will ripen in September, when the stalks should be cut off, and spread on mats to dry, and afterward threshed out and cleaned, and put up in bags for use.

B E T O N I C A [or Veronica, so called from the Veretones, an ancient people of Spain, who first used this plant], Betony.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is tubulous, cut at the brim into five parts. The flower is of one leaf, of the lip kind, with a cylindrical incurved tube; the upper lip is roundish, plain, erect, and entire; the lower lip is cut into three parts, the middle segment being broad, roundish, and indented at the end. It hath four awl-shaped stamina, two long and two shorter, which incline to the upper lip; these have roundish summits. The germen is quadripartite, supporting a style of the length and

and figure of the stamina, crowned by a bifid stigma. The germen afterward becomes four naked oval seeds, lodged in the empalement.

This genus of plants is ranged in the first section of Linnæus's twelfth class, intitled Didynamia Gymnospermia, the flower having two long and two shorter stamina, which are succeeded by naked seeds.

The SPECIES are,

1. *BETONICA (Officinalis)* spicâ interruptâ, corollarum laciniâ labii intermediâ emarginatâ. Flor. Leyd. Prod. 316. *Betony with an interrupted spike, and the middle segment of the lower lip of the flower indented at the end.* *Betonica purpurea.* C. B. P. 235. *Purple or Wood Betony.*
2. *BETONICA (Danica)* foliis radicalibus ovato-cordatis, caulinis lanceolatis obtusis spicâ crassiore. *Betony whose under leaves are heart-shaped, those on the stalks spear-shaped and obtuse, and a thicker spike of flowers.* *Betonica major Danica.* Park. Theat. 615. Mor. Hist. 3. 365.
3. *BETONICA (Alpina)* foliis triangularibus obtusis spicâ brevior. *Betony with obtuse triangular leaves, and a shorter spike of flowers.* *Betonica minima Alpina Helvetica.* Park. Theat. 650.
4. *BETONICA (Orientalis)* spicâ integrâ, corollarum laciniâ labii intermediâ integerrimâ. Flor. Leyd. Prod. 316. *Betony with a whole spike, and the middle segment of the lower lip entire.* *Betonica Orientalis angustifolia & longifolia folio, spicâ florum crassiori.* Tourn. Corol. 13.
5. *BETONICA (Incana)* foliis lanceolatis obtusis incanis spicâ florum crassiori. *Betony with obtuse, spear-shaped, hoary leaves, and a thicker spike of flowers.* *Betonica Italica incana flore carneo.* Barrel. Icon. 340.

The first sort grows naturally in woods and on shady banks in most parts of England, so is seldom cultivated in gardens. This is the sort which is used in medicine, and is greatly esteemed as a vulnerary herb. There is a variety of this with a white flower, which I have often found growing naturally in Kent.

The second sort grows naturally in Denmark. This differs greatly from our common sort, the lower leaves being much broader and heart-shaped; those upon the stalks are spear-shaped and rounded at the end, and the stalks are larger, stand upright, and are terminated by thicker spikes of flowers. These differences are constant, for I have many years propagated them by seeds, and have never found the plants so raised to vary.

The third sort grows naturally upon the Alps, where it seldom rises more than four inches high; and when cultivated in a garden, not above seven or eight. The leaves of this are much broader at the base than those of the common sort, and are very different in their shape, being triangular and blunt at the end. The flowers grow in very short close spikes, on the top of the stalks. These differences constantly hold in the plants raised from seeds.

The fourth sort was discovered by Dr. Tournefort in the Levant. The leaves of this are very long, narrow, and hairy, and are neatly crenated on their edges. The flowers grow in very close thick spikes at the top of the stalks, which are larger, and of a lighter purple colour than those of the common sort.

The fifth sort grows naturally in Italy, upon the hills, from whence I received the seeds. The leaves of this sort are broader, and not so long as those of the common sort, and are hoary; the stalks are shorter and much thicker, as are also the spikes of flowers, than those of the common, and the flowers are larger and of a flesh colour. This sort constantly keeps the same from seeds.

There is another sort which Tournefort and others mention, by the title of *Betonica rubicundissima flore montis aurei*; which differs but little from the fifth, except in the colour of the flower, so I doubt of its being specifically different from that.

All the sorts are perennial plants, which may be propagated by seeds, or parting of their roots. They are all very hardy, but require a shady situation and

a moist stiff soil, in which they will thrive better than in rich ground. The best time to transplant and separate the roots is in the autumn, but the seeds should be sown in the spring upon a shady border, and when the plants come up, they will require no other care but to keep them clean from weeds, and to thin them where they are too close.

These all of them flower in May and June, and the seeds ripen in August.

BETONICA AQUATICA. See SCROPHULARIA.

BETONICA PAULI. See VERONICA.

BETULA, the Birch-tree.

The CHARACTERS are,

It hath male and female flowers, at separate distances on the same tree; the male flowers are collected in a cylindrical katkin, which is scaly, loose, and imbricated on every side; each scale having three flowers, which have two minute scales on the side. The flower is composed of three equal florets, fixed to the empalement by a single scale; each floret is of one leaf, divided into four oval segments which spread open; these have four small stamina, crowned by double summits. The female flowers grow in a katkin, in the same manner as the male. The common katkin is imbricated, having three scales which are every way opposite, fastened to the central string or axis, having two heart-shaped flowers pointing toward the apex, where it is situated. They have no visible petals, but a short oval germen, supporting two bristly styles, which are the length of the scales of the empalement, and crowned with a plain stigma. It hath no pericarpium, but the seeds are included in the scales of the katkin, which are oval and winged.

This genus of plants is ranged in the fourth section of Linnæus's twenty-first class, intitled Monœcia Tetrandia, there being male and female flowers on the same plant, and the male having four stamina.

The SPECIES are,

1. *BETULA (Alba)* foliis ovatis acuminatis serratis. Hort. Cliff. 442. *Birch-tree with oval sawed leaves ending in points; the common Birch-tree.*
2. *BETULA (Nana)* foliis orbiculatis. Flor. Lap. 266. *Birch-tree with round crenated leaves.* *Betula pumila foliis subrotundis.* Amman. *Dwarf Birch.*
3. *BETULA (Lenta)* foliis cordatis oblongis acuminatis serratis. Lin. Sp. Plant. 983. *Birch-tree, with oblong, pointed, heart-shaped, sawed leaves.*
4. *BETULA (Nigra)* foliis rhombo-ovatis acuminatis duplicato-serratis. Lin. Sp. Plant. 982. *Birch-tree with rhomboid, oval, pointed leaves, which are doubly sawed.* *Betula nigra Virginiana.* Pluk. Alm. 67. *Black Virginia Birch-tree.*

The first is the common Birch-tree, which is so well known as to need no description. This is not much esteemed for its wood, but however it may be cultivated to advantage upon barren land, where better trees will not thrive; for there is no ground so bad, but this tree will thrive in it; for it will grow in moist springy land, or in dry gravel or sand, where there is little surface: so that upon ground which produced nothing but moss, these trees have succeeded so well, as to be fit to cut in ten years after planting, when they have been sold for near 10 l. per acre standing, and the after produce has been considerably increased. And as many of the woods near London, which were chiefly stocked with these trees, have been of late years grubbed up, so the value of these plantations have advanced in proportion. Therefore those persons who are possessed of such poor land, cannot employ it better, than by planting it with these trees, especially as the expence of doing it is not great.

The best method to cultivate this tree, is to furnish yourself with young plants from the woods where they naturally grow, and are generally found there in great plenty; but in places where there are no young plants to be procured near, they may be raised from seeds, which should be carefully gathered in the autumn, as soon as the scales under which they are lodged begin to open, otherwise they will soon fall out and be lost: the seeds are small, so should not be buried deep

B E T

deep in the ground. The autumn is the best season to sow them, and in a shady situation, the plants will thrive better than when they are exposed to the full sun; for in all places where there are any large trees their seeds fall, and the plants come up well without care; so that if the young plants are not destroyed by cattle, there is generally plenty of them in all the woods where there are any of these trees. These wild plants should be carefully taken up, so as not to destroy their roots. The ground where they are to be planted, will require no preparation; all that is necessary to be done, is to loosen it with a spade or mattock, in the places where the plants are to stand, making holes to receive their roots, covering them again when the plants are placed, and closing the earth hard to their roots. If the plants are young, and have not much top, they will require no pruning; but where they have bushy heads, they should be shortened to prevent their being shaken and displaced by the wind. When the plants have taken root, they will require no other care, but to cut down the great weeds which would over-hang the plants; which may be done with a sickle, being careful not to cut or injure the young trees. This need not be repeated oftener than two or three times in a summer the two first years, after which time the plants will be strong enough to keep down the weeds, or at least be out of danger from them.

These may be planted any time from the middle of October till the middle of March, when the ground is not frozen; but in dry land the autumn is the best season, and the spring for moist. The distance which they should be planted, is six feet square, that they may soon cover the ground, and by standing close, they will draw each other up; for in situations where they are much exposed, if they are not pretty close, they will not thrive so well.

If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterward they may be cut every seventh or eighth year, if they are designed for the broom-makers only; but where they are intended for hoops, they should not be cut oftener than every twelfth year.

The expence of making these plantations in places where the young plants can be easily procured, will not exceed forty shillings per acre, and the after expence of cleaning about twenty shillings a year more; so that the whole will not be more than 3*l*. and if the land so planted be of little value, the proprietor cannot make better use of his money; for when the wood is cut, it will repay the expence with interest, and a perpetual stock upon the ground. I have seen several of these plantations made upon land which would not lett for one shilling per acre, which has produced from 10 to 12*l*. an acre, clear of the expence in cutting, and this every twelfth year. The broom-makers are constant customers for Birch, in all places within twenty miles of London, or where it is near water carriage; in other parts the hoop-benders are the purchasers; but the larger trees are often bought by the turners, and the wood is used for making ox-yokes, and other instruments of husbandry.

In some of the northern parts of Europe, the wood of this tree is greatly used for making of carriages and wheels, being hard and of long duration. In France it is generally used for making wooden shoes. It makes very good fuel.

In some places these trees are tapped in the spring, and the sap drawn out to make Birch wine, which has been recommended for the stone and gravel, as is also the sap unfermented. The bark of the Birch-tree is almost incorruptible. In Sweden the houses are covered with it, where it lasts many years. It frequently happens, that the wood is entirely rotten, and the bark perfectly sound and good.

The second sort grows naturally in the northern parts of Europe, and upon the Alps; this seldom rises above two or three feet high, having slender branches, garnished with round leaves, but seldom produces either male or female flowers here. It is preserved in some

B I D

curious gardens for the sake of variety, but is a plant of no use.

The third and fourth sorts grow naturally in North America, from whence their seeds have been brought to Europe, and many of the plants have been raised, which thrive very fast here. In Canada these trees grow to a large size, where the third sort is called Merisier. The natives of that country make canoes of the bark of these trees, which are very light, and of long duration.

Both these sorts may be propagated by seeds in the same manner as the first, and are equally hardy; some of the trees now begin to produce their katkins in England, so that we may hope to have plenty of their seeds of our own growth, for at present we are supplied with them from America. As these grow more vigorously than the common sort, and thrive on the most barren ground, they may be cultivated to great advantage in England, for their wood is much esteemed in Canada, where the trees grow to a large size: and they are by no means an unsightly tree in parks, for their stems are strait, the bark smooth, and their leaves are much larger than those of the common Birch, so may be planted in such places where few other trees will thrive.

BIDENS. Tourn. Inst. R. H. 362. tab. 262. Lin. Gen. Plant. 840. Water Hemp Agrimony.

The CHARACTERS are,

The common empalement is erect, and often equal, composed of small, oblong, concave leaves; it hath a compound flower; the middle or disk is composed of hermaphrodite florets, which are funnel-shaped and quinquesfid. These have five short capillary stamina, with cylindrical summits, and an oblong germen supporting a single style the length of the stamina, crowned by two oblong reflexed stigma. The female florets which compose the border are naked; these are all succeeded by a single, angular, obtuse seed, having two or more bristles or teeth, by which they fasten themselves to whatever passes by them when ripe.

This genus is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia aequalis, the flowers being composed of hermaphrodite and female florets, which are succeeded by seeds.

There are several species of this plant, which are seldom admitted into gardens, some of which are common weeds in England, therefore I shall only mention those which are frequently preserved in the gardens of the curious.

1. BIDENS (*Froncosa*) foliis pinnatis serratis feminibus erecto-constantibus calycibus frondosis corollis radiatis. Lin. Sp. Plant. 832. *Water Hemp Agrimony with winged sawed leaves, seeds standing erect, a very bushy empalement, and radiated flower.* Bidens Canadensis latifolia flore luteo. Tourn. Inst. 362.
2. BIDENS (*Nodiflora*) foliis oblongis integerrimis caule dichotomo floribus solitariis sessilibus. Lin. Sp. Plant. 832. *Hemp Agrimony with oblong entire leaves, a forked stalk, and a single flower growing close to the stalk.* Bidens nodiflora brunnellæ folio. Hort. Elth. 52.
3. BIDENS (*Nivea*) foliis simplicibus subhastatis serratis petiolatis, floribus globosis, pedunculis elongatis feminibus lævibus. Lin. Sp. Plant. 833. *Hemp Agrimony with single sawed leaves having scot-stalks, globular flowers with longer foot-stalks, and smooth seeds.* Bidens scabra flore nivea, folio trilobato. Hort. Elth. 55.
4. BIDENS (*Frutescens*) foliis ovatis serratis petiolatis, caule fruticoso. Hort. Cliff. 399. *Hemp Agrimony with oval sawed leaves having foot-stalks, and a shrubby stalk.*
5. BIDENS (*Scandens*) foliis ternatis acutis serratis caule scandente floribus paniculatis. *Three-leaved Hemp Agrimony, with pointed sawed lobes, a climbing stalk, and flowers growing in panicles.* Chrysanthemum trifoliatum scandens, flore luteo semine longo rostrato bidente. Sloan. Cat. Jam. 125.
6. BIDENS (*Bullata*) foliis ovatis serratis, inferioribus oppositis, superioribus ternatis intermedio majore. Lin. Sp.

Sp. Plant. 833. *Hemp Agrimony with oval sawed leaves, the lower ones growing opposite, but the upper having three lobes, the middle of which is the largest.* *Crysanthemum conyzoides nodiflorum semine rostrato bidente.* Sloan. Cat. Jam. 126.

The first sort grows naturally in Virginia, Maryland, and Canada, where it is often a troublesome weed. It rises about three feet high, sending out many horizontal branches, garnished with trifoliate leaves, deeply sawed on their edges; the flowers are produced at the end of the branches in small clusters, which are yellow, and succeeded by oblong square seeds, having two crooked horns, by which they fasten themselves to the clothes of those who pass near them. There are two sorts of this, one whose flowers have a short empalement, which is Tournefort's broad-leaved Canada Bidens; the other hath a leafy empalement, and is by Jussieu distinguished by the title of *Capite folioso*. But I am not very sure of their being distinct species, though I have many years cultivated both; for their seeds when ripe spread so far, that in a small garden they cannot be kept separate. It is easily propagated by seeds sown in the spring, in an open situation, where, if the seeds are permitted to scatter, the plants will come up the following spring, and two or three of them may be transplanted where they are to grow, and after they are rooted, will require no farther care. This is an annual plant, so decays soon after the seeds are ripe.

The second sort grows naturally in warm countries. This is an annual plant, which rises near three feet high, dividing upward into several branches, which are garnished with oblong entire leaves; the flowers come out single at the divisions of the branches, sitting close; these are white, and succeeded by smooth seeds.

This sort must be sown upon a moderate hot-bed in the spring, and afterward treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June, and their seeds ripen in autumn, soon after which the plants will decay.

The third sort grows naturally in South Carolina, and also at Campeachy. This is also an annual plant, which rises three feet high, dividing upward into many slender branches, whose joints are far asunder; the leaves come out by pairs at each joint upon long slender foot-stalks, which are oval, ending in a point. The flowers grow at the extremity of the branches in small globular heads, which are very white, standing upon very long foot-stalks, and are succeeded by smooth seeds. This must be sown upon a hot-bed, and treated as the former. It flowers and seeds about the same time.

The fourth sort rises with a shrubby stalk to the height of six or seven feet, dividing into many branches, whose joints are very distant, at each of which are placed two oval leaves, slightly sawed on their edges, and have short foot-stalks. The flowers are produced at the end of the branches in small clusters, each standing upon a long naked foot-stalk; these are succeeded by flat seeds, having two short teeth at their extremity. I received the seeds of this sort from Carthage in New Spain. This is propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot, and plunged into a fresh hot-bed, and treated as other tender plants from the same countries, and in autumn placed in the stove: the following summer they will abide some years with proper management.

The fifth sort rises with a climbing slender stalk to the height of ten feet, dividing into many branches, garnished with trifoliate sawed leaves: the flowers grow in large panicles at the end of the branches; they are yellow, and are succeeded by flat seeds having two teeth. This plant grows naturally in Jamaica, from whence I received the seeds. It must be treated in the same manner as the former sort, and will continue two or three years.

The sixth sort is annual. This rises about two feet high, and sends out several lateral shoots, which at the bottom have oval leaves placed by pairs at the joints, but upward they are trifoliate, the middle lobe being very large, and the two side ones small; the flowers are produced at the wings of the leaves upon short leafy foot-stalks, and are yellow, but very small. It flowers in July, and the seeds ripen in autumn; the seeds of this must be sown upon a hot-bed, and treated as the second sort.

BIFOLIUM, Twyblade. See OPHRYS.

BIGNONIA. Tourn. Inst. 164. Lin. Gen. Plant. 677. [M. Tournefort called this plant Bignonia, in memory of abbot Bignon, librarian to Lewis XIV. king of France, he being a great encourager of learning.] The Trumpet Flower, or Scarlet Jasmine.

The CHARACTERS are,

The empalemet is cup-shaped, quinquesid, and of one leaf. The flower is of the ringent, or grinning kind, tubulous, with long chaps, which are swelling, and bell-shaped, divided into five parts at the top; the two upper segments are reflexed, and the under spread open; it hath four awl-shaped stamina shorter than the petal, two longer than the other, having oblong reflexed summits. In the center is an oblong germen, supporting a slender style, crowned by a roundish stigma. The germen afterward becomes a bivalve pod, with two cells, filled with compressed winged seeds, lying over each other imbricatum.

This genus of plants is ranged in the second division of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamina, and the seeds included in a capsule.

The SPECIES are,

1. BIGNONIA (*Radicans*) foliis pinnatis, foliolis incisis, caule geniculis radicatis. Lin. Hort. Cliff. 217. *Bignonia with winged leaves, which are cut on their edges, and roots coming out at the joints of the stalk.* Bignonia Americana Fraxini folio flore amplo Phœnicio. Tourn. Inst. 164.
2. BIGNONIA (*Catalpa*) foliis simplicibus cordatis, caule erecto, floribus diandris. Lin. Sp. Plant. 622. *Bignonia with single heart-shaped leaves, an upright stalk, and flowers with two stamina.* Bignonia Urucu foliis, flore sordide albo, intus maculis purpureis & luteis adperso, filiquâ longissimâ & angustissimâ. Catesb. Carol. 1. p. 49.
3. BIGNONIA (*Frutescens*) foliis pinnatis, foliolis lanceolatis acutis serratis, caule erecto, floribus paniculatis erectis. *Bignonia with winged leaves, having acute sawed lobes, an upright stalk, and flowers growing in panicles erect.* Bignonia arbor flore luteo Fraxini folio. Plum. Sp. Plant. 5.
4. BIGNONIA (*Pubescens*) foliis conjugatis cirrhosis foliolis cordato-lanceolatis foliis imis simplicibus. Vir. Cliff. 59. *Bignonia with conjugated leaves having tendrils, the leaves spear-shaped, and the lower leaves single.* Bignonia Americana Capreolis donata filiqua brevior. Breyn. Ic. 33.
5. BIGNONIA (*Unguis Cati*) foliis conjugatis, cirrho brevissimo arcuato tripartito. Lin. Sp. Plant. 623. *Bignonia with conjugated leaves, and short arched tendrils, divided into three parts.* Bignonia Americana capreolis aduncis donatâ, filiquâ longissimâ. Tourn. Inst. 164.
6. BIGNONIA (*Æquinoctialis*) foliis conjugatis cirrhosis, foliolis ovato-lanceolatis, pedunculis bifloris filiquis linearibus. Lin. Sp. 869. *Bignonia with conjugated leaves, having tendrils, whose lobes are oval, spear-shaped, and linear pods.*
7. BIGNONIA (*Sempervirens*) foliis simplicibus lanceolatis caule volubili. Lin. Sp. Plant. 623. *Bignonia with single spear-shaped leaves, and a twining stalk.* Gelseminum sive Jasminum luteum odoratum Virginianum scandens & sempervirens. Park. Catesb. 1. p. 53.
8. BIGNONIA (*Pentaphylla*) foliis digitatis foliolis integerrimis obovatis. Hort. Cliff. 497. *Bignonia with fingered leaves, whose lobes are entire.* Bignonia arbor pentaphylla flore roseo. Plum. Sp. Plant. 5.

9. BIGNO-

9. **BIGNONIA** (*Leucoxylon*) foliis digitatis foliolis integerrimis ovatis acuminatis. Lin. Sp. Plant. 870. *Bignonia with fingered leaves, whose lobes are oval, pointed, and entire.* *Leucoxylon arbor filiquosa, quinis foliis, floribus Nerii, alato semine.* Pluk. Alm. 215. tab. 200. f. 4. *commonly called in America Tulip Flower.*
10. **BIGNONIA** (*Paniculata*) foliis conjugatis cirrhosis, foliolis cordato-ovatis, floribus racemoso-paniculatis. Lin. Sp. Plant. 623. *Bignonia with conjugated leaves, having tendrils, the lobes oval and heart-shaped, and flowers in branching panicles.* *Bignonia bifolia scandens, flore violaceo odoro, fructu ovato duro.* Plum. Cat. 5.
11. **BIGNONIA** (*Cerulea*) foliis bipinnatis foliolis lanceolatis integris. Lin. Sp. Plant. 625. *Bignonia with double winged leaves, which are entire and spear-shaped.* *Arbor Guajaci latiore folio, Bignoniae flore caeruleo, fructu duro in duas partes diffiliente seminibus alatis imbricatim positis.* Catesb. Carol. 1. p. 42.
12. **BIGNONIA** (*Crucigera*) foliis conjugatis cirrhosis foliolis cordatis. Vir. Cliff. 60. *Bignonia with conjugated heart-shaped leaves, having tendrils, and a stalk having tendrils.* *PseudoApocynum folliculis maximis obtusis seminibus anplissimis alismembranaceis.* Mor. Hist. 3. p. 62.
13. **BIGNONIA** (*Capreolata*) foliis conjugatis cirrhosis foliolis cordato-lanceolatis, foliis imis simplicibus. Lin. Sp. 870. *Bignonia with conjugated heart-shaped leaves, having tendrils, whose lower leaves are single, growing in panicles, and long compressed pods.*
14. **BIGNONIA** (*Triphylla*) foliis ternatis glabris, foliolis ovatis acuminatis, caule fruticoso erecto. Lin. Sp. 870. *Smooth three-leaved Bignonia, with oval lobes ending in a point, and a shrubby stalk.* *Bignonia frutescens triphylla glabra, siliquis longis compressis.* Houst. Cat.

The first sort grows naturally in Virginia and Canada. It hath large rough stems, which send out many trailing branches, putting out roots at their joints, which fasten themselves to the trees in their natural places of growth, whereby they climb to a great height; and in Europe, where they are generally planted against walls, they fasten themselves thereto by their roots, which strike into the mortar of the joints so strongly, as to support their branches, and will rise to the height of forty or fifty feet. The branches are garnished with winged leaves at every joint, placed opposite, composed of four pair of small leaves, terminated by an odd one; these are sawed on their edges, and end in a long sharp point. The flowers are produced at the ends of the shoots of the same year, in large bunches; these have long swelling tubes, shaped somewhat like a trumpet, from whence it had the appellation of Trumpet Flower. They are of an Orange colour, and appear the beginning of August.

This sort is very hardy, so will thrive in the open air; but as the branches trail, they must be supported, therefore are usually planted against walls or buildings, where, if the branches have room, they will spread to a great distance, and rise very high, so are very proper for covering of buildings, which are unsightly. They may also be trained up against the stems of trees, where they may be so managed, as to make a fine appearance when they are in flower.

This is propagated by seeds, but the young plants so raised do not flower in less than seven or eight years; therefore those which are propagated by cuttings or layers from flowering plants, are most esteemed, because they will flower in two or three years after planting. The old plants also send out many suckers from the roots, which may be taken off, and transplanted where they are to remain, for these plants will not transplant safely if they are old.

The necessary culture for these plants after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to about two feet long, that young shoots may be obtained for flowering the following summer; these plants are of long duration. There are some in gardens which have been planted more than sixty years, which are now very vigorous, and produce flowers in plenty every season.

If the plants are propagated by seeds, they should be sown upon a moderate hot-bed to bring them up, which should be soon inured to the open air, to prevent their being drawn up weak; and the first winter these young plants should be screened from hard frost, which will kill their tender shoots; but the spring following they may be planted in the full ground, in a nursery-bed, at a foot distance from each other, where they may remain one or two years to get strength, and afterwards be planted where they are designed to grow.

The second sort was brought into England by Mr. Catesby, about forty years past, who found it growing naturally on the back of South Carolina, at a great distance from the English settlements. It is now very plenty in the English gardens, especially near London, where there are some of them near twenty feet high, with large stems, and have the appearance of trees.

This sort rises with an upright stem, covered with a smooth brown bark, and sends out many strong lateral branches, garnished with very large heart-shaped leaves, placed opposite at every joint. The flowers are produced in large branching panicles toward the end of the branches, of a dirty white colour, with a few purple spots, and faint stripes of yellow on their inside. The tube of the flower is much shorter, and the upper part more expanded, than those of the former sort, and the segments deeper cut, and waved on their edges. The flowers are in America succeeded by very long taper pods, filled with flat winged seeds, lying over each other like the scales of fish. In England there has not as yet been any of the pods produced, but the seeds are annually brought over from South Carolina. These should be sown in pots, and plunged into a moderate hot-bed to bring up the plants, which should be inured to the open air by degrees; and, in the beginning of June, placed abroad in a sheltered situation till autumn, when they should be placed under a common frame to screen them from frost in winter; but in mild weather they must be fully exposed to the open air. The following spring these may be taken out of the pots, and planted in a nursery-bed, in a warm situation, where they may remain two years to get strength, and afterwards planted in the places where they are designed to remain. These plants, when young, are frequently injured by frost, for they shoot pretty late in the autumn, so that the early frosts often kill the extremity of their branches; but as the plants advance in strength, they become more hardy, and are seldom injured but in very severe winters. It is late in the spring before these trees come out, which has often caused persons to believe they were dead; and some have been so imprudent, as to cut them down on that supposition, before the tree was well known.

It may also be propagated by cuttings, which should be planted in pots in the spring before the trees begin to push out their shoots, and plunged into a moderate hot-bed, observing to shade them from the sun in the middle of the day, and refresh them occasionally with water, which must not be given to them in too great plenty. In about six weeks these will have taken root, and made shoots above, so should have plenty of air admitted to them constantly, and hardened by degrees to bear the open air, into which they should be removed, and treated in the same manner as the seedling plants, and the spring following planted out into a nursery-bed, as is before directed.

As these trees have very large leaves, they require a sheltered situation; for where they are much exposed to strong winds, their leaves are often torn and rendered unsightly, and many times their branches are split and broken by the winds, their leaves being so large, as that the wind has great force against them. These produce their flowers in August. They delight in a light moist soil, where they make great progress, and in a few years will produce flowers. It is generally known in the gardens by the Indian title of Catalpa.

The

B I G

The third sort is a native of the warmer parts of America, where it was discovered by father Plumier, who made a drawing of it, and gave the title of *Clematitis* to it, which he afterward altered to *Bignonia*, when he became better acquainted with Tournefort's System of Botany. This rises with an upright stem, to the height of twelve or fourteen feet, sending out many side branches, garnished at every joint by two long winged leaves placed opposite; the small leaves which compose these, are long and spear-shaped, ending in a point, and slightly sawed on their edges, each leaf being composed of six pair, terminated by an odd one. The flowers are produced in loose panicles at the ends of the branches, and are shaped like those of the other species, but spread open more at the top. These are yellow, and succeeded by compressed pods about six inches long, having two rows of flat winged seeds, like those of the other species.

I received this sort first in 1729, from La Vera Cruz, in New Spain, where the late Dr. Houstoun found it growing naturally in great plenty; since which time I have received the seed from the island of Bermuda, by the title of Candle Wood.

It is propagated by seeds, which must be sown on a hot-bed, and the plants afterward transplanted into separate small pots, filled with light fresh earth, and plunged into a fresh hot-bed to bring them forward, that they may obtain strength before winter; in the autumn they must be removed into the bark-stove, and during the winter should have but little water, but in summer they must be frequently refreshed with it, but not given in too great plenty. The plants should constantly remain in the bark-stove, and be treated in the same manner as other tender plants from those countries. The third year from seed they will flower, but they do not produce seeds in England.

The fourth sort grows naturally in Virginia, and several other parts of America; this hath very slender trailing stalks, which must be supported; in the places where it naturally grows, the branches fasten themselves by their tendrils to whatever plants are near them, and extend to a great distance. In this country they require the assistance of a wall, and to have a good aspect, for they are impatient of much cold, so should be sheltered in severe frost; the branches are garnished with oblong leaves, which are green all the year; these are often single at bottom, but upward are placed by pairs opposite at each joint; the flowers are produced at the wings of the leaves, which are yellow, and shaped like those of the Foxglove. These appear in August, but are not succeeded by pods in this country. This is propagated by seeds, which should be sown on a moderate hot-bed, and treated in the same manner as the first sort. When these plants are planted in the full ground against walls, the ground about the roots should be covered in the autumn with some old tanners bark to keep out the frost in winter; and in very severe frost, the branches should be covered with mats, to prevent their being destroyed. With this management I have had the plants flower very well in the Chelsea garden.

The fifth sort hath slender stalks like the former, which require the same support; these are garnished with small oval leaves, which are entire, placed opposite at every joint; at the same places come out the tendrils, by which they fasten themselves to the plants which grow near them; these end in three distinct parts; the flowers come out from the wings of the leaves, which are shaped like those of the former sort, but are smaller, and are not succeeded by seeds in this country. This grows naturally in Carolina and the Bahama Islands, but will live in the open air, if it is planted against a wall to a south aspect, and sheltered in very severe frost. It is propagated in the same manner as the former sort.

The sixth sort hath very weak slender branches, which put out tendrils at the joints, by which they fasten themselves to the neighbouring plants: at each joint

B I G

there are four leaves, two on each side opposite; these are oval pointed, and waved on their edges, of a bright green, and continue through the year; the branches ramble very far where they have room: the flowers are large, yellow, and are produced at the joints of the stalks, but are not succeeded by pods in this country. I received this sort from La Vera Cruz, in New Spain; but it thrives against a warm wall in the open air very well, with the same treatment as the two former sorts.

The seventh sort grows naturally in South Carolina, where it spreads over the hedges, and at the season of flowering, perfumes the air to a great distance; it also grows in some parts of Virginia, but not in so great plenty as at Carolina. The inhabitants there call it Yellow Jasmine, I suppose from the sweet odour of its flowers.

This rises with slender stalks, which twist themselves round the neighbouring plants, and mount to a considerable height; the branches are garnished with oblong pointed leaves, which come out single and opposite to each other at every joint; these remain green through the year. The flowers come out from the wings of the leaves at every joint, sometimes but two, at other times four at each joint; these stand erect, are trumpet-shaped, yellow, and have a very sweet scent; and in the countries where they naturally grow, they are succeeded by short taper pods, filled with small winged seeds.

The plants of this sort, when young, are impatient of cold, so must be sheltered in the winter until they have obtained strength, when they should be planted against a warm wall, and in winter protected from frost by coverings of mats, and the ground about their roots covered with tan. With this management I have had them flower very well in the Chelsea garden. It is propagated by seeds in the same manner as the former sorts.

The eighth sort was sent me from Jamaica by the late Dr. Houstoun. This rises with an upright stem near twenty feet high, sending out many lateral branches, covered with a white bark. The leaves come out opposite at the joints upon long foot-stalks; they are composed of five oval stiff leaves, which are joined in one center at their base, where they are narrow, but widen toward the top, where they are rounded and obtuse. They are of a pale green, inclining to white on their under side; the flowers are produced at the ends of the branches four or five together, on very short foot-stalks; they are narrow at bottom, but the tube enlarges upward, and at the top spreads open wide, of a pale bluish colour, and smell sweet; they are succeeded by taper crooked pods about four inches long, which are filled with oval compressed seeds, with wings of a silver colour.

This sort is a native of the warmer parts of America, therefore will not thrive in this country, but in a stove. It is propagated by seeds, which must be sown on a hot-bed, and the plants treated in the same manner as the fourth sort.

The ninth sort I received from Barbadoes, by the title of White Wood. This rises with an upright stem to the height of forty feet, in the natural country of its growth; and the seeds are dispersed by wind to the neighbouring lands, where the plants come up in great plenty. This and the former sort have been generally confounded, and supposed to be the same, but the growing plants are extremely different; for the under leaves of this are sometimes composed of five, at other times of four oval leaves; and on the upper part of the branches, they come out single, placed by pairs opposite: these are as large as those of the Bay-tree, and of equal thickness, rounded at their end; each of these have a long foot-stalk, whereas those of the former join at their base to one center. The flowers of this sort are produced single at the wings of the leaves, which have a narrow tube near two inches long, but spread open very wide at the top, where they are cut into five unequal segments, which are fringed on their borders. The flowers are

white,

white, and have an agreeable odour, but the pod I have not seen.

The plants must be preserved in the bark-stove, and treated as the fourth sort. It is propagated by seeds, and will also take root from cuttings in the summer, if they are planted in pots, and plunged into a bark-bed. It has flowered several years in the Chelsea garden, in August.

The tenth sort was sent me from La Vera Cruz, by the late Dr. Houstoun; this rises with ligneous stalks, which put out tendrils at the joints, whereby they fasten themselves to the neighbouring plants; the leaves come out on each side the branches, upon pretty long foot-stalks, two at each joint opposite, which are heart-shaped and entire, having a fine hairy down on their under side. The flowers grow in loose spikes at the end of the branches, which are tubulous, and do not spread much at the top; they are of a Violet colour, and smell very sweet. These in their native country are succeeded by oval, hard, ligneous seed-vessels, which open in four parts, and are full of compressed winged seeds.

This sort is propagated by seeds, which must be sown on a hot-bed, and the plants must be treated in the same manner as the third sort, for they will not thrive in this country unless they are placed in the bark-stove.

The eleventh sort grows naturally in the Bahama Islands, from whence Mr. Catesby sent the seeds in 1724, and many of the plants were raised in the gardens near London. This, in the country where it grows naturally, rises to the height of twenty feet, sending out many lateral branches, garnished with compound winged leaves, each having eleven alternate wings, with spear-shaped small lobes, which grow alternate, and are entire; at the ends of the branches the flowers are produced in very loose panicles; the foot-stalks branching into three or four, each sustaining a single blue flower, with a long swelling tube, cut into five unequal segments at the top, where it spreads open. The flowers are succeeded by oval seed-vessels, which open in two parts, and are filled with flat winged seeds.

The twelfth sort hath a woody stem, sending out many branches, which have four narrow borders or wings running longitudinally, so as to resemble a square stalk; the leaves are produced by pairs, on each side the branches; they are heart-shaped, smooth, and have short foot-stalks; these have tendrils coming out by their foot-stalks, which fasten themselves to the plants which grow near them, and thereby rise to a great height. The flowers are produced in small clusters from the wings of the leaves, which have pretty long tubes, spread open at the top, and are of a pale yellow colour; these are succeeded by flat pods a foot in length, which have two rows of flat winged seeds, joined to the intermediate partition.

This sort was sent me from Campeachy, where it naturally grows, and rises to the tops of the tallest trees, to whose branches these plants fasten themselves by their tendrils or claspers, and are thereby supported. This is propagated by seeds, which must be sown on a hot-bed, and the plants treated in the same manner as the fourth sort; for they will not thrive in this country, unless they have a warm stove, where the branches will rise to the height of twenty feet in three years; and if permitted, will spread to a great distance. It has flowered in the garden at Chelsea, but doth not produce pods in England.

The thirteenth sort was sent me from Campeachy, by Mr. Robert Millar; this hath woody stalks, which rise to a great height, climbing on the trees which grow near it, fastening themselves to their branches by its claspers, and sending out many ligneous branches, which are garnished with oval heart-shaped leaves, by fours, two on each side, growing opposite at the joints; these are covered on their under side with a soft hairy down, of a yellowish colour. The flowers are produced in loose panicles at the end of the

branches, which are shaped like those of the Fox-glove, and are of a pale yellow colour, and are succeeded by flat pods a foot long, having a border on each side, and contain two rows of flat winged seeds. This plant is tender; so must be constantly kept in the bark-stove, and treated in the same manner as the fourth sort. It is propagated by seeds, which must be obtained from the country where it grows naturally, for it doth not produce any in England.

The fourteenth sort was sent me from La Vera Cruz in New Spain, by the late Dr. Houston. This hath a woody stem covered with an Ash-coloured bark, which rises to the height of ten feet, sending out many side branches, garnished with trifoliate leaves, placed opposite at each joint, which are very smooth, oval, and ending in points. The flowers come out at the extremity of the branches in loose panicles, and are of a dirty white colour. These are succeeded by flat narrow pods, containing two rows of flat winged seeds.

This sort is propagated by seeds, which must be sown on a hot-bed, and the plants afterward treated as the fourth sort, and must constantly remain in the bark-stove.

BIRCH-TREE. See BETULA.

BISCUTELLA. Lin. Gen. Plant. 724. Thlaspidium: Tourn. Inst. R. H. 214. tab. 101. Buckler Mustard, or Bastard Mithridate Mustard.

The CHARACTERS are,

The empalement is composed of four leaves, which are pointed. The flower hath four petals, placed in form of a cross, which are obtuse and spread open; it hath six stamens, four long and two short, placed opposite, having single summits. In the center is situated an orbicular compressed germen, supporting a single permanent style, crowned with an obtuse stigma; the germen afterward becomes a plain, compressed, erect capsule, with two convex lobes, having two cells, terminated by the rigid style, which is joined to the side of the partition, each cell containing one compressed seed.

This genus of plants is ranged in the first section of Linnæus's fifteenth class, intitled Tetradinamia Sili-culosa, the flower having four long, and two short stamens, and are succeeded by very short pods.

The SPECIES are,

1. BISCUTELLA (*Auriculata*) calycibus nectario utrinque gibbis, filiculis in stylum coeuntibus. Lin. Hort. Cliff. 329. *Buckler Mustard, with the cup of the nectarium swelling on each side, and small pods joined to the style.* Thlaspidium hirsutum calyce floris auriculato. Inst. R. H. 214.
2. BISCUTELLA (*Didyma*) filiculis orbiculato-didymis à stylo divergentibus. Hort. Cliff. 329. *Buckler Mustard, with a double orbicular pod diverging from the style.* Thlaspidium Monspeliense hieracii folio hirsuto. Tourn. Inst. 214.
3. BISCUTELLA (*Apula*) hirsuta foliis oblongis dentatis semiamplexicaulibus floribus spicatis stylo brevior. *Hairy Buckler Mustard, with oblong indented leaves which half embrace the stalk, flowers growing in spikes, and a shorter style.* Thlaspidium Apulum spicatum. Tourn. Inst. 214.

The first sort grows naturally in the south of France and Italy, where it rises about a foot high; but in a garden generally grows near two feet high, dividing into several branches; and at every joint there is one oblong entire leaf a little indented, those on the lower part of the stalk being broader and more obtuse than those on the upper. The flowers are produced at the ends of the branches in loose panicles, which are composed of four obtuse petals of a pale yellow colour; these are succeeded by double, round, compressed seed-vessels, swelling in the middle, where is lodged a single, round, flat seed, the style of the flower standing upright between the two small vessels, joined to their borders.

The second sort grows naturally in the south of France, Italy, and Germany, from whence I received

B I S

the seeds, and dried samples of the plant, which are not more than six inches high, though they are the entire plants with their roots, but in the garden they grow almost two feet high. This hath many long, narrow, hairy leaves, spreading near the ground, which are deeply indented on each side, resembling those of Hawkweed; from the center arises the stalk, which divides upward into many small branches, having no leaves on them, and are terminated by loose panicles of yellow flowers, composed of four petals, placed in form of a cross. These are succeeded by round compressed seed-vessels like the former, but are smaller, and the style of the flowers bends from them.

The third sort sends out many oblong hairy leaves, which are slightly indented on their edges; from among these there arises a hairy branching stalk, which grows two feet high, and at each joint is placed one oblong indented leaf, which half embraces the stalk at the base; each branch is terminated by a close spike of pale yellow flowers, which are succeeded by round compressed seed-vessels like the other sorts, but the style of the flower, which is joined to them, is shorter than those of the other species.

These are all annual plants, which perish soon after they have perfected their seeds. These should be sown either in spring, or the autumn, upon a border of light earth, in an open situation, where they are to remain for good. Those which are sown in autumn will come up in about three weeks, and the plants will live through the winter without any protection, so will flower earlier the following summer, whereby good seeds may always be obtained; whereas those which are sown in the spring, do, in bad seasons, decay before their seeds are ripe. The autumnal plants flower in June, and the spring in July, and their seeds ripen about six weeks after, which, if permitted to scatter, there will be plenty of young plants produced without any care.

These require no farther culture, but to keep them clean from weeds, and thin the plants where they are too close, leaving them eight or nine inches asunder. They are preserved in the gardens of those who are curious in botany, but they have no great beauty to recommend them. I have cultivated these sorts many years, and have never observed either of them to vary, therefore make no doubt of their being distinct species.

BISERRULA. Lin. Gen. Plant. 800. *Pelecinus*. Tourn. Inst. 417. tab. 234.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is erect, and slightly indented at the top in five equal parts, the two upper standing at a distance. The flower is papilionaceous, having a large roundish standard, whose edges are reflexed. The wings are oblong, but shorter than the standard; and the obtuse keel is of the same length with the wings, bending upward. It hath ten stamina, nine of which are joined, and the other single, with their ends pointing upward. In the center is situated an oblong compressed germen, supporting an awl-shaped style, crowned by a single stigma; these are included in the keel. The germen afterward becomes a flat narrow pod, indented on both edges like the saw of the sword fish, having two cells, filled with kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled *Diadelphia Decandria*, the flower having ten stamina, joined in two bodies.

We have but one SPECIES of this genus, which is, **BISERRULA.** (*Pelecinus*.) Hort. Cliff. 361. We have no English name for this plant. *Pelecinus vulgaris*. Tourn. Inst. 417.

This is an annual plant, which grows naturally in Italy, Sicily, Spain, and the south of France. It sends out many angular stalks, which trail on the ground, subdivided into many branches, garnished with long winged leaves, composed of many pair of lobes, terminated by an odd one; these are heart-shaped: toward the upper part of the branches come out the

B I X

foot-stalk of the flowers, which sustains several small Butterfly flowers, of a purplish colour, collected together, which are succeeded by plain pods, about one inch long, indented on both sides the whole length, divided in the middle by a longitudinal nerve, containing two rows of kidney-shaped seeds.

It is propagated by seeds, which in this country should be sown in the autumn, on a bed of light earth, where the plants will come up in about three weeks, and will live in the open air very well. These should be sown where they are designed to remain, or transplanted very young; for when they are large, they will not bear removing. When the plants are come up, they will require no other care, but to keep them clean from weeds; and where they are too near, they should be thinned to about a foot distance from each other. They flower in June, and the seeds ripen in September.

The seeds of this plant may also be sown in the spring, and treated in the same manner as before directed; but these will not flower till the middle or end of July, so unless the autumn proves warm, they will not ripen seeds; for which reason I have directed their being sown in the autumn, as soon as they are ripe. Two or three of these plants may be allowed a place in gardens for the sake of variety, but they have not much beauty.

BISLINGUA. See *Ruscus*.

BISTORTA [so called, because the root is turned or wreathed into various rings or spires,] *Bistort*, or *Snakeweed*.

This genus is joined to the *Polygonum* by Dr. Linnæus. This plant flowers in May, and if the season proves moist, will continue to produce new spikes of flowers till August: it may be propagated by planting the roots in a moist shady border, either in spring or autumn, which will soon furnish the garden with plants, for it greatly increases by its creeping roots.

The roots of this plant have been recommended for tanning of leather, but the trouble of procuring them in a sufficient quantity is too great to answer the intention.

BIVALVULAR, or *Bivalve* [of *bivalvis*] *Husk*, is one that opens and gapes the whole length, like a door that opens in two parts.

BIXA. Lin. Gen. Plant. 581. *Urucu*. Sloan. Cat. Jam. *Orleana*. H. L. *Mitella*. Tourn. Inst. 242. *Anotta*, by the French *Roucou*.

The CHARACTERS are,

It hath a plain, small, obtuse empalement, which is permanent; the flower hath a double series of petals, the outer consisting of five, which are large, oblong, and equal, the inner of the same number and shape, but narrower. It hath a great number of bristly stamina, which are but half the length of the petals, terminated by erect summits. In the center is situated an oval germen, supporting a slender style of the same length with the stamina, crowned by a bifid, compressed, parallel stigma. The germen afterward becomes an oval heart-shaped capsule, a little compressed, covered with sharp bristles, opening with two valves, with one cell, and filled with angular seeds, adbering to a linear receptacle, which runs longitudinally through the capsule.

This genus is ranged in the first section of Linnæus's thirteenth class, intitled *Polyandria Monogynia*, the flower having many stamina and one style.

We have but one SPECIES of this genus, viz.

BIXA. (*Orellana*.) Hort. Cliff. 211. *The Arnotta*, or *Anotta*, by the French *Roucou*. *Mitella Americana maxima tinctoria*. *Achioti* of *Hernandez*.

This shrub grows naturally in the warm parts of America, where it rises with an upright stem to the height of eight or ten feet, sending out many branches at the top, forming a regular head. These are garnished with heart-shaped leaves ending in a point, which have long foot-stalks, and come out without any order. The flowers are produced in loose panicles at the end of the branches, of a pale Peach colour, having large petals, and a great number of bristly stamina of the same colour, in the center. After the flower

flower is past, the germen becomes a heart-shaped, or rather a mitre-shaped seed-vessel, covered on the outside with bristles, opening with two valves, and filled with angular seeds, covered with a red pulp or paste, which colours the hands of those who touch it, and is collected for the use of dyers and painters.

This plant is propagated by seeds, which are annually brought from the West-Indies in plenty. These should be sown in a small pot, filled with light rich earth, and plunged into a hot-bed of tanners bark; where, if the bed is of a proper temperature of heat, the plants will appear in about a month after: when these are about an inch high, they should be shaken out of the pot and carefully separated, so as not to tear off their tender roots, and each planted in a small pot filled with some rich light earth, and plunged into a fresh hot-bed of tanners bark, observing to shade them every day until they have taken new root; after which they must be treated as other tender plants from the same country, by admitting fresh air to them in proportion to the warmth of the season; and when the heat of the tan declines, it should be turned up to the bottom, and, if necessary, some fresh tan added to renew the heat. The plants must be refreshed three times a week with water in summer, but they must not have it in great quantities, for their roots often rot with much wet. If the plants are raised early in the spring, and properly managed, they will be a foot and a half high by the autumn, when they should be removed into the bark-stove, and plunged into the tan-bed. During the winter, they must have but little water, and while the plants are young, they must have a good share of warmth, otherwise they are very subject to cast their leaves, and frequently lose their tops, which renders them unsightly. They must be constantly kept in the bark-stove, for those plants which have been placed in a dry stove, have never made much progress. I have had many of these plants seven or eight feet high, with strong stems and large heads, but have only had one produce flowers; nor have I heard of its flowering in any of the gardens in Europe, for in the Dutch gardens they have no plants of any size.

The paste which surrounds the seeds is taken off, by steeping the seeds in hot water, and with the hands washed until the seeds are clean; then after pouring away the water, they leave the sediment to harden, and make it up in balls, which are sent to Europe, where they are used in dying and painting. It is also used by the Americans to dye their chocolate, and the natives used to paint their bodies with it when they went to the wars.

BLADDER-NUT. See STAPHYLEA.

BLATTARIA. See VERBASCUM.

BLIGHTS.

There is nothing so destructive to a fruit garden as blights; nor is there any thing in the business of gardening which requires more of our serious attention, than the endeavouring to prevent or guard against this great enemy of gardens.

In order therefore to remedy this evil, it will be necessary first to understand the true causes of blights; for, although many curious persons have attempted to explain the causes of them, yet very few of them have come near the truth, except the Rev. and learned Dr. Hales, who hath, in his curious book, intitled *Vegetable Statics*, given us some accurate experiments upon the growth and perspiration of plants, together with the various effects the air hath upon vegetables; that by carefully attending thereto, together with diligent observations, we need seldom to be at a loss how to account for the causes of blights whenever they may happen.

But here I cannot help taking notice of the several causes of blights, as they have been laid down by some of our modern writers on gardening, together with their various methods prescribed to prevent their destruction of fruits, &c.

Some have supposed, that blights are usually pro-

duced by an easterly wind, which brings vast quantities of insects eggs along with it from some distant place; which, being lodged upon the surface of the leaves and flowers of fruit-trees, cause them to shrivel up and perish. To cure this distemper, they advise the burning of wet litter on the windward side of the trees, that the smoke thereof may be carried to them by the wind, which they suppose will stifle and destroy those insects, and thereby cure the distemper.

Others direct the use of Tobacco-dust, or to wash the trees with water wherein Tobacco-stalks have been infused for twelve hours, which, they say, will destroy these insects, and recover the trees; and Pepper-dust, scattered upon the blossoms of fruit-trees, has been recommended as very useful in this case: and there are some that advise the pulling off the leaves of the tree, as the best remedy when they are shrivelled up and wither; and to cut off the smaller branches when they produce crooked and unnatural shoots, and to sprinkle the tree with a watering-pot, or a hand-engine.

These conjectures concerning blights, how specious soever they may appear at first sight, yet, when duly considered, will be found far short of the true cause, as will hereafter be shewn.

But let us now examine the true causes of blights, so far as we have been enabled to judge from repeated observations and experiments.

1. Blights then are often caused by a continued dry easterly wind for several days together, without the intervention of showers, or any morning dew, by which the perspiration in the tender blossoms is stopped, so that in a short time their colour is changed, and they wither and decay; and if it so happen, that there is a long continuance of the same weather, it equally affects the tender leaves; for their perspiring matter is hereby thickened and rendered glutinous, closely adhering to the surface of the leaves, and becomes a proper nutriment to those small insects, which are always found preying upon the leaves and tender branches of fruit-trees, whenever this blight happens; but it is not these insects which are the first cause of blights, as hath been imagined by some; though it must be allowed, that whenever these insects meet with such a proper food, they multiply exceedingly, and are instrumental in promoting the distemper; so that many times, when the season proves favourable to them, and no proper care hath been taken to prevent their mischief, it is surprising to think how whole walls of trees have suffered by this infection.

The best remedy for this distemper, that I have yet known succeed, is, gently to wash and sprinkle over the trees, from time to time, with common water (that is, such as hath not had any thing steeped in it;) and the sooner this is performed (whenever we apprehend danger,) the better; and if the young and tender shoots seem to be much infected, wash them with a woollen cloth, so as to clear them, if possible, from all this glutinous matter, that their respiration and perspiration may not be obstructed; and if we place some broad flat pans or tubs of water near the trees, that the vapours exhaled from the water may be received by the trees, it will keep their tender parts in a ductile state, and greatly help them; but whenever this operation of washing the trees is performed, it should be early in the day, that the moisture may be exhaled before the cold of the night comes on; especially if the nights are frosty: nor should it be done when the sun shines very hot upon the wall, which would be subject to scorch up the tender blossoms.

Another cause of blights in the spring is, sharp hoary frosts, which are often succeeded by hot sunshine in the day time; which is the most sudden and certain destroyer of fruits that is known; for the cold of the night starves the tender parts of the blossoms, and the sun rising hot upon the walls before the moisture is dried from the blossoms (which, being in small globules, collects the rays of the sun,) a scalding heat

is thereby acquired; which scorches the tender flowers, and other parts of plants.

But that blights are frequently no more than an inward weakness or distemper in trees, will evidently appear, if we consider how often it happens, that trees against the same wall, exposed to the same aspect, and equally enjoying the advantages of sun and air, with every other circumstance which might render them equally healthy; yet very often are observed to differ greatly in their strength and vigour; and as often we observe the weak trees to be continually blighted, when the vigorous ones, in the same situation shall escape very well; which must, therefore, in a great measure, be ascribed to their healthy constitution. This weakness, therefore, in trees, must proceed either from a want of a sufficient supply of nourishment to maintain them in perfect vigour, or from some ill qualities in the soil where they grow, or, perhaps, from some bad quality in the stock, or inbred distemper of the buds or cyons, which they had imbibed from their mother tree, or from mismanagement in the pruning, &c. all which are productive of distempers in trees, and of which they are with difficulty cured. Now, if this is occasioned by a weakness in the tree, we should endeavour to trace out the true cause; first, whether it has been occasioned by ill management in the pruning, which is too often the case; for how common is it to observe Peach-trees trained up to the full length of their branches every year, so as to be carried to the top of the wall in a few years after planting, when at the same time the shoots for bearing have been so weak, as scarcely to have strength to produce their flowers: but this being the utmost of their vigour, the blossoms fall off, and, many times, the branches decay, either the greatest part of their length, or quite down to the place where they were produced; and this, whenever it happens to be the case, is ascribed to a blight.

Others there are, who suffer their trees to grow just as they are naturally disposed, during the summer season, without stopping of shoots, or disburdening their trees of luxuriant branches; by which means two, three, or four shoots shall exhaust the greatest part of the nourishment of the trees all the summer; which shoots, at the winter pruning, are entirely cut out; so that the strength of the tree was employed only in nourishing useless branches, while the fruit branches are thereby rendered so weak, as not to be able to preserve themselves. The remedies to this evil shall be explained in the article of PRUNING Peach-trees, &c.

But if the weakness of the tree proceeds from an inbred distemper, it is the better way to remove the tree at first; and after renewing your earth, plant a new one in its place.

Or if your soil be a hot burning gravel or sand, in which your Peach-trees are planted, you will generally find this will be constantly their case, after their roots have got beyond the earth of your borders; for which reason, it is much more advisable to dig them up, and plant Grapes, Figs, Apricots, or any other sort of fruit, which may do well in such a soil, rather than to be annually disappointed of your hopes; for, by a variety of experiments, it hath been found, that Apricots attract and imbibe moisture with a much greater force than Peaches and Nectarines; and consequently, are better able to attract the nutritive particles from the earth, than the other, which require to be planted in a generous soil, capable of affording them a sufficiency of nourishment without much difficulty: and it is in such places we often see Peaches do wonders, especially if assisted by art; but as for the Vine and Fig-tree, they perspire very slowly, and are very often in an imbibing state (so that a great part of that fine racy flavour, with which their fruits abound when planted in a dry soil, is probably owing to those refined aerial principles, which are collected when in a state of respiration;) and therefore, as these trees delight not in drawing much watery nourishment from the earth, so they will much

better succeed in such a soil, than in one that is more generous: we should therefore always endeavour to suit the particular sorts of fruits to the nature of our soil, and not pretend to have all sorts of fruit good in the same.

But there is another sort of blight, against which it is very difficult to guard our fruit-trees; this is sharp, pinching, frosty mornings, which often happen at the time when the trees are in flower, or while the fruit is very young, and occasion the blossoms or fruit to drop off; and, sometimes, the tender parts of the shoots and leaves are greatly injured thereby.

The only method yet found out to prevent this mischief, is, by carefully covering the walls, either with mats, canvas, reeds, &c. which being fastened so as not to be disturbed with the wind, and suffered to remain on during the night, and taking them off every day, if the weather permits, is the best and surest method that hath yet been found successful; which, although it has been slighted, and thought of little service by some, yet the reason of their being not so serviceable as has been expected, was, because they have not been rightly used, either by suffering the trees to remain too long covered; by which means the younger branches and leaves have been rendered too weak to endure the open air, when they are exposed to it; which has often proved of worse consequence to trees, than if they had remained entirely uncovered, or by incautiously exposing them to the air, after having been long covered.

Whereas, when the covering before-mentioned has been performed as it ought to be, it has proved very serviceable to fruits; and many times, when there has been almost a general destruction of fruits in the neighbouring gardens, there has been a plenty of them in such places where they have been properly covered: and though the trouble may seem to some very great, yet, if these coverings are fixed near the upper part of the wall, and are fastened to pulleys, so as to be drawn up, or let down, it will be soon and easily performed; and the success will sufficiently repay the trouble.

But there is another sort of blight that sometimes happens later in the spring, viz. in April or May, which is often very destructive to orchards, and open plantations, and against which we know of no remedy. This is what is called a fire blast; which, in a few hours, hath not only destroyed the fruit and leaves, but, many times, parts of trees, and, sometimes, entire trees have been killed by it.

This is supposed to be effected by volumes of transparent flying vapours, which, among the many forms they revolve into, may sometimes approach so near to an hemisphere, or hemicylinder, either in their upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays.

The learned Boerhaave, in his Theory of Chemistry, observes, "That those white clouds which appear in summer time, are, as it were, so many mirrors, and occasion excessive heat: these cloudy mirrors are sometimes round, sometimes concave, polygonous, &c. When the face of the heavens is covered with such white clouds, the sun, shining among them, must, of necessity, produce a vehement heat; since many of his rays, which would otherwise, perhaps, never touch our earth, are hereby reflected to us: thus, if the sun be on one side, and the clouds on the opposite one, they will be perfect burning glasses: and hence the phenomenon of thunder."

"I have sometimes, continues he, observed a kind of hollow clouds, full of hail and snow, during the continuance of which the heat was extreme; since, by such condensation, they were enabled to reflect much more strongly: after this came a sharp cold, and then the clouds discharged their hail in great quantities, to which succeeded a moderate warmth. Frozen concave clouds therefore, by

"their

"their great reflexions, produce a vigorous heat; and the same, when resolved, excessive cold."

Whence (as Dr. Hales observes) we see, that blasts may be occasioned by the reflexions of the clouds, as well as by the above-mentioned refraction of dense transparent vapours.

Against this enemy to fruits, &c. as hath been said, there is no guard to our fruit-trees, nor any remedy to cure it: but as this more frequently happens in close plantations (where the stagnating vapours from the earth, and the plentiful perspirations from the trees, are pent in for want of a free air to dissipate and dispel them; which are often observed, in still weather, to ascend in so plentiful a manner, as to be seen by the naked eye, but especially with reflecting telescopes, so as to make a clear and distinct object become dim and tremulous,) than in those that are planted at a greater distance, or are not surrounded with hills or woods; this directs us, in the first planting of kitchen-gardens and orchards, &c. that we should allow a greater distance between the trees, and to make choice of clear healthy situations, that the air may freely pass between the trees to dissipate those vapours before they are formed into such volumes, whereby the circumambient air will be clear, and less subject to injuries; as also the fruits which are produced in this clearer air, will be much better tasted than those that are surrounded with a thick rancid air; for as fruits are often in a respiring state, they consequently, by imbibing a part of these vapours, are rendered crude and ill-tasted, which is often the case with a great part of our fruits in England.

BLITUM. Lin. Gen. Plant. 14. *Chenopodio-morus*. Boerh. Ind. *Morocarpus*. Rupp. Strawberry Blite.

The CHARACTERS are,

It hath a tripartite spreading empalement, which is permanent; the flower hath no petals, but one bristly stamina the length of the empalement, with a double summit. In the center is situated an oval pointed germen supporting two styles, the length of the stamina, with a single stigma. The empalement afterward becomes an oval compressed capsule, including one globular compressed seed, the size of the capsule.

This genus of plants is ranged in the second order of Linnæus's first class, intitled *Monandria Digynia*, the flower having but one stamina and two styles.

The SPECIES are,

1. **BLITUM** (*Capitatum*) *capitellis spicatis terminalibus*. Hort. Upsal. 3. *Blite with spikes terminated by little heads.* *Chenopodio-morus major*. Boerh. Ind. alt. 2. 91. Commonly called *Strawberry Blite*, or *Strawberry Spinach*.
2. **BLITUM** (*Virgatum*) *capitellis sparsis lateralibus*. Hort. Upsal. 3. *Blite with small heads growing scatteringly from the sides of the stalks.* *Chenopodio-morus minor*. Boerh. Ind. alt. 2. 91. *Wild Atriplex with a Mulberry fruit.*
3. **BLITUM** (*Tartaricum*) *foliis triangularibus acutè dentatis, capitellis simplicibus lateralibus*. *Blite with triangular leaves sharply indented, and single heads proceeding from the sides of the stalks.* *Blitum fragiferum maximum polyspermum*. Amman. Ruth.

The first sort grows naturally in Spain and Portugal, but hath been long preserved in the English gardens. This is an annual plant, which hath leaves somewhat like those of Spinach; the stalk rises about two feet and a half high, the lower part of which is garnished with leaves of the shape with those at bottom, but smaller; the upper part of the stalk hath flowers coming out in small heads at every joint, and is terminated by a small cluster of the same: after the flowers are past, the little heads swell to the size of Wood Strawberries, and when ripe have the same appearance; being very succulent, and full of a purple juice, which stains the hands of those who bruise them, of a deep purple colour.

The second sort grows naturally in the south of France and Italy. This seldom grows more than one foot high, with smaller leaves than the first, but of the same shape; the flowers are produced at the wings

of the leaves, almost the length of the stalk, which are small, and collected in little heads, which are shaped like those of the first, but smaller and not so deeply coloured.

The seeds of the third sort were sent me by the late Dr. Amman, who was professor of botany at Petersburg. This rises near three feet high; the leaves are triangular, ending in very acute points, as do also the indentures on the edges of the leaves. The flowers come out from the wings of the leaves in small heads, which are succeeded by berries of the same shape and colour as those of the first, but smaller. This sort differs from the first in the shape and indentures of the leaves, and in having leaves placed between the berries the whole length of the stalk, which is not terminated by heads as the first, but hath leaves above the heads.

These are all of them annual plants, which will drop their seeds if permitted, and the plants will come up in plenty the following spring: or if the seeds of either of the sorts are sown in March or April, upon a bed of common earth, in an open situation, the plants will come up in a month or five weeks after; and, if they are to remain in the place where they are sown, will require no other care but to keep them clear from weeds, and to thin them out, so as to leave them six or eight inches apart; and in July the plants will begin to shew their berries, when they will make a pretty appearance. But many people transplant them into the borders of the flower-gardens, and others plant them in pots, to have them ready for removing to court-yards, or to place upon low walls, among other annual flowers, to adorn those places.

When these plants are designed to be removed, they should be transplanted before they shoot up their flower-stems, for they will not bear transplanting well afterward: and if they are planted in pots, they will require to be duly watered in dry weather, otherwise the plants will stint, and not grow to any size; and, as the flower-stems advance, they should be supported by sticks; for if they are not, the branches will fall to the ground, when the berries are grown pretty large and weighty.

BLOODWORT. See *LAPATHUM*.

BOCCONIA.

This plant was so called after the Reverend Paul Boccone, of Sicily, who has published some curious books of botany.

The CHARACTERS are,

The flower hath an empalement composed of two oval, obtuse, concave leaves; it hath four narrow petals, with a great number of very short stamina, crowned by erect summits, which are the length of the empalement. In the center is situated a roundish germen, contracted at both ends, supporting a single style, which is bifid at the top, crowned by a single stigma. The germen afterward becomes an oval fruit, contracted at both ends, and a little compressed, having one cell, full of pulp, including a single round seed.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled *Polyandria Monogynia*, the flower having many stamina and one style.

There is but one SPECIES of this genus at present known, which is,

BOCCONIA. (*Frutescens*.) Lin. Sp. Plant. 505. *Bocconia racemosa, sphondylii folio tomentoso*. Plum. Nov. Gen.

This plant is called, by Sir Hans Sloane, in his Natural History of Jamaica, *Chelidonium majus arborescens, foliis quercinis*; or *Greater Tree Celandine with Oak leaves*.

It is very common in Jamaica, and several other parts of America, where it grows to the height of ten or twelve feet, having a strait trunk as large as a man's arm, which is covered with a white smooth bark. At the top it divides into several branches, on which the leaves are placed alternately. These leaves are eight or nine inches long, and five or six broad, deeply

sinuated, sometimes almost to the mid-rib, and are of a fine glaucous colour; so that this plant makes a beautiful variety among other exotic plants in the stove. The whole plant abounds with a yellow juice like the greater Celandine, which is of an acrid nature; so that it is used by the inhabitants of America, to take off warts, and spots from the eyes.

It is propagated by seeds, which should be sown in a pot filled with light fresh earth, early in the spring, and plunged into a hot-bed of tanners bark, observing to water it now and then gently, otherwise the seeds will not grow. When the plants are come up, they should be each transplanted into separate small pots filled with light sandy earth, and plunged into the hot-bed again, observing to shade the glasses in the heat of the day, until the plants have taken root. They must be also gently watered, but it should be done sparingly while they are young; for their stems being very tender, and full of juice, will rot, if they receive too much moisture; but after their stems are become woody, they will require it often, especially in hot weather; when also they should have a large share of air, by raising the glasses of the hot-bed. The plants, in two months after transplanting, will have filled these small pots with their roots; therefore they should be shaken out of them, and planted into pots one size larger, filled with light fresh earth, and plunged into the bark-stove, where they should have a good share of fresh air in warm weather. With this management I have raised these plants upwards of two feet high in one season, which were also very strong in their stems: they must be constantly kept in the stove, being too tender to thrive in this country in any other situation. This plant has flowered in the physic garden at Chelsea, and perfected seeds; but if it were not to flower, the singular beauty of the plant renders it worthy of a place in every curious collection of plants; and it seems the Indians were very fond of it, for Hernandez tells us, the Indian kings planted it in their gardens.

BOERHAAVIA. This genus of plants was so named by Monsr. Vaillant, professor of botany at Paris, in honour of the famous Dr. Boerhaave, who was professor of botany, chemistry, and physic, in the university of Leyden.

The CHARACTERS are,

The flower hath no empalement, and but one bell-shaped petal, which is pentangular and entire. It hath in some species one, and in others two short stamina, crowned by a double globular summit. The germen is situated below the receptacle, supporting a short slender style, with a kidney-shaped stigma; the germen afterward becomes a single oblong seed, having no cover.

This genus of plants is ranged in the first section of Linnaeus's first class, intitled Monandria Monogynia, the flower having but one stamina and a single style.

The SPECIES are,

1. **BOERHAAVIA** (*Erecta*) caule erecto glabro. Lin. Sp. Plant. 3. *Boerhaavia with an erect stalk.* Boerhaavia Solanifolia erecta glabra, floribus carneis laxius dispositis. Houst. MSS.
2. **BOERHAAVIA** (*Diffusa*) caule diffuso. Lin. Sp. Plant. 3. *Boerhaavia with a diffused stalk.* Boerhaavia Solanifolia major. Vail. Def. 50.
3. **BOERHAAVIA** (*Scandens*) caule scandente floribus dian-drin. Lin. Sp. Plant. 3. *Boerhaavia with a climbing stalk.* Boerhaavia alfinis folio scandens, floribus pallide luteis majoribus in umbellae modum dispositis femine aspero. Houst. MSS.
4. **BOERHAAVIA** (*Coccinea*) foliis ovatis, floribus laterali-bus compactis, caule hirsuto procumbente. *Boerhaavia with oval leaves, flowers coming from the wings of the leaves in close beads, and a hairy trailing stalk.* Boerhaavia Solanifolia procumbens & hirsuta floribus coccineis compactis. Houst. MSS.

The first sort was discovered by the late Dr. Hous-toun, at La Vera Cruz, in 1731. This rises with an upright smooth stalk, two feet high, and at each joint hath two oval pointed leaves growing opposite,

upon foot-stalks, an inch long, of a whitish colour on their under side. At the joints, which are far asunder, come out small side branches, growing erect; these, as also the large stalk, are terminated by loose panicles of flesh-coloured flowers, which are each succeeded by oblong glutinous seeds.

The seeds of the second sort were sent me by the same gentleman from Jamaica, where it naturally grows. This sends out many diffused stalks a foot and a half or two feet long, garnished with small roundish leaves at each joint. The flowers grow very scatteringly upon long branching foot-stalks from the wings of the leaves, as also at the end of the branches, which are of a pale red colour, and are succeeded by seeds like the former.

The third sort was sent me from Jamaica with the former. This sends out several stalks from the root, which divide into many branches, and trail over whatever plants grow near them, and rise to the height of five or six feet, garnished with heart-shaped leaves, growing by pairs at each joint upon long foot-stalks, which are of the colour and consistence of those of the greater Chickweed. The flowers grow in loose umbels at the extremity of the branches, which are yellow, and are succeeded by small, oblong, viscous seeds.

The fourth sort was sent me from Jamaica with the two former: this sends out many trailing hairy stalks, which divide into smaller branches, garnished with oval leaves at every joint; and at the wings of the leaves come out the naked foot-stalks, sustaining a small close head of scarlet flowers, which are very fugacious, seldom standing more than half a day before their petals drop; these are succeeded by short oblong seeds.

The first, second, and fourth sorts are annual plants, which decay in autumn, but the third sort is perennial: they are all tender plants, so will not thrive in the open air in England; they are propagated by seeds, which must be sown on a hot-bed in the spring, and when the plants are fit to be removed, they should be each planted in a small pot and plunged into the hot-bed, and treated as other tender exotic plants. When they are grown too tall to remain under a common frame, a plant or two of each sort should be placed in the stove; the other may be turned out of the pots, and planted in a warm border, where, if the season proves warm, they will perfect their seeds; but as these are subject to fail in cold seasons, so those in the stove will always ripen their seeds in autumn; the third sort may be preserved in a warm stove two or three years.

BOMBAX. Lin. Gen. Plant. 580. Ceiba. Plum. Nov. Gen. 32. Silk Cotton-tree.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is bell-shaped, erect, and quinquesid. The flower is quinquesid and spreading, the petals are oval and concave. It hath many awl-shaped stamina, which are the length of the petal, crowned with oblong incurved summits. In the center is situated the round germen, supporting a slender style the length of the stamina, with a round stigma. The empalement afterward becomes a large, oblong, turbinate capsule, having five cells, opening with five valves, which are ligneous, containing many roundish seeds, wrapped in a soft down, and fixed to a five-cornered column.

This genus of plants is ranged in the fifth order of Linnaeus's sixteenth class, intitled Monadelphia Polyandria, the flower having many styles and stamina joined to a column.

The SPECIES are,

1. **BOMBAX** (*Ceiba*) floribus polyandris, foliis quinatis. Jacq. Amer. 26. *Silk Cotton-tree whose flowers have many styles, and leaves with five lobes.* Ceiba viticis foliis caudice aculeato. Plum. Nov. Gen. 42.
2. **BOMBAX** (*Pentandrum*) floribus pentandris. Jacq. Amer. 26. *Silk Cotton-tree whose flowers have five styles.* Ceiba viticis foliis caudice glabro. Plum. Nov. Gen. 42.

3. **BOMBAX** (*Villosus*) foliis quinque-angularibus villosis, caule geniculato. *Silk Cotton with five-cornered hairy leaves, and a jointed stalk.*

The first and second sorts grow naturally in both Indies, where they arrive to a great magnitude, being some of the tallest trees in those countries; but the wood is very light, and not much valued, except for making of canoes, which is the chief use made of them. Their trunks are so large, as when hollowed, to make very large ones. In Columbus's first voyage it was reported, there was a canoe seen at the island of Cuba, made of the hollowed trunk of one of these trees, which was ninety-five palms long, and of a proportional width, which would contain a hundred and fifty men: and some modern writers have affirmed, that there are trees of these sorts now growing in the West-Indies, so large, as not to be fathomed by sixteen men, and so tall as that an arrow cannot be shot to their top.

These trees generally grow with very strait stems; those of the first sort are closely armed with short strong spines, but the second hath very smooth stems, which in the young plants are of a bright green, but after a few years, they are covered with a grey, or Ash-coloured bark, which turns to a brown as the trees grow older: they seldom put out any side branches till they arrive to a considerable height, unless their leading shoot be broken or injured. The branches toward their top are garnished with leaves composed of five, seven, or nine oblong smooth lobes, which are spear-shaped, and join to one center at their base, where they adhere to the long foot-stalk. These fall away every year, so that for some time the trees are naked, and before the new leaves come out, the flower-buds appear at the end of the branches, and soon after the flowers expand, which are composed of five oblong purple petals, with a great number of stamina in the center; when these fall off, they are succeeded by oval fruit larger than a swan's egg, having a thick ligneous cover, which, when ripe, opens in five parts, and is full of a dark short cotton, inclosing many roundish seeds as large as small Pease.

The down which is inclosed in these seed-vessels is seldom used, except by the poorer inhabitants to stuff pillows or chairs, but it is generally thought to be unwholesome to lie upon.

These two species have been supposed the same by many writers on natural history, who have affirmed, that the young trees only have prickles on their trunks, and as they grow old, their trunks become smooth; but from many years experience I can affirm, that the seeds which have been sent me of the two sorts, have always produced plants of the different kinds for which they were sent, and continue the same in plants, which are more than twenty years growth.

There was a few years past a fine plant of another sort in the garden of the late Duke of Richmond, at Goodwood, which was raised from seeds that came from the East-Indies. The stem of this was very strait and smooth; the leaves were produced round the top upon very long foot-stalks, each being composed of seven or nine long, narrow, silky, small lobes, joined at their base to the foot-stalk, in the same manner as those of the two former, but they were much longer, and reflexed backward, so that at first sight it appeared very different from either of them. This may be the species, titled by Jacquin, *Bombax floribus pentandris, foliis septenatis*. Amer. 26.

The third sort was sent me from the Spanish West-Indies, where it grows naturally, but I do not know to what size; the plants which have been raised here, have soft herbaceous stalks very full of joints, and do not appear as if they would become woody, for the plants of several years growth have soft pithy stems. The leaves come out on long hairy foot-stalks toward the top of the plants, these have the appearance of those of the Mallow-tree, but are larger, and of a thicker consistence; on their under

side are covered with a short, brown, hairy down, and are cut on their edges into five angles. These plants have not as yet flowered in England, nor have I received any information what flower they produce; but by the pods and seeds, it appears evidently to be of this genus. The down inclosed in these pods, is of a fine purple colour; and I have been informed that the inhabitants of the countries where the trees grow naturally, spin it, and work it into garments, which they wear without dyeing it of any other colour.

I received a few years since, a few pods of another sort from Panama, which were not so large as those of the common, but were rounder. The down of these was red, but the plants raised from the seeds were so like those of the third sort, as not to be distinguished from them, so I doubt of their being distinct species. I also received some seeds from Siam, which produced plants of the same kind, so that these trees may be common to many of the hot countries.

The plants are propagated by seeds, which must be sown on a hot-bed in the spring; if the seeds are good, the plants will appear in a month, and those of the two first sorts will be strong enough to transplant in a month after, when they should be each planted in a small pot, filled with fresh loamy earth, and plunged into a moderate hot-bed of tanners bark, being careful to shade them from the sun till they have taken fresh root; after which they should have a large share of air admitted to them when the weather is warm, to prevent their being drawn up weak; they must also be frequently refreshed with water, which must not be given in large quantities, especially the third sort, whose stalks are very subject to rot with much moisture. In this bed they may remain till autumn (provided there is room for the plants under the glasses) but if the heat of the bed declines, the tan should be stirred up, and fresh added to it; and if the plants have filled the pots with their roots, they should be shifted into pots a little larger; but there must be care taken not to over-pot them, for nothing is more injurious to these plants, than to be put into large pots, in which they will never thrive. In the autumn they must be removed into the bark-stove, where they must constantly remain, being too tender to thrive in this country in any other situation. In winter they must have but little wet, especially if they cast their leaves; but in the summer they should be frequently refreshed with water, and in warm weather must have plenty of fresh air admitted to them. With this management the plants will make great progress, and in a few years will reach the glasses on the top of the stove, especially if the building is not pretty lofty.

The plants make an agreeable variety in a large stove where they have room to grow, their leaves having a different appearance from most other plants; but as they are several years old before they flower in the countries where they grow naturally, there is little hopes of their producing any in England.

BONDUC. See *GUILANDINA*.

BONTIA. Lin. Gen. Plant. 709. Plum. Nov. Gen. 23. Hort. Elth. 49. Barbadoes Wild Olive.

The CHARACTERS are,

It hath a small erect empalement, which is quinquefid and permanent. The flower is of the ringent kind, having a long cylindrical tube, gaping at the brim; the upper lip is erect and indented, the lower lip is trifid and turns backward. It hath four awl-shaped stamina, which are as long as the petal, and incline to the upper lip, two of them being longer than the other, having single summits. In the center is situated the oval germen, supporting a slender style the length of the stamina, crowned by a bifid obtuse stigma. The germen afterward becomes an oval berry with one cell, including a nut of the same form.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled *Didynamia Angiospermia*, the flower having two long and two short stamina, and the seeds are included in a cover.

The

The SPECIES are,

1. BONTIA. (*Daphnoides*.) Lin. Sp. Plant. *Barbadoes Wild Olive*. Bontia arborefcens thymelææ facie. Plum. Nov. Gen. 32.
2. BONTIA (*Germinans*) foliis oppositis, pedunculis spicatis. Lin. Sp. Plant. 891. Bontia with leaves growing opposite, and spiked foot-stalks of flowers. Avicennia. Flor. Zeyl. 57.

The first sort is greatly cultivated in the gardens at Barbadoes, for making of hedges, than which there is not a more proper plant for those hot countries, it being an Evergreen, and of quick growth. I have been informed, that from cuttings (planted in the rainy season, when they have immediately taken root) there has been a complete hedge, four or five feet high, in eighteen months. And as this will very well bear cutting, it is formed into a very close thick hedge, which makes a beautiful appearance. In England it is preserved in stoves, with several curious plants of the same country. It may be raised from seeds, which should be sown on a hot-bed early in the spring (that the plants may acquire strength before winter.) When the plants are come up, they must be transplanted out each into a separate half-penny pot filled with light fresh earth, and plunged into a moderate hot-bed of tanners bark, observing to water and shade them until they have taken root; after which they must have a large share of air in warm weather, and be often refreshed with water. In winter they must be placed in the stove, where they should have a moderate degree of warmth, and but little water during that season. In summer they must have a great share of air, but will not do well if exposed abroad, especially in cold summers; so that they should remain in the stove among plants which require a great share of air, which may be admitted by opening the glasses in very hot weather. With this management, these plants will produce flowers and fruit in three or four years from seed. They may also be propagated by cuttings, which should be planted in the summer. They must be put into pots filled with light rich earth, and plunged into a moderate hot-bed, observing to water and shade them until they have taken root; after which they must be treated as hath been directed for the seedling plants. These plants being evergreen, and growing in a pyramidal form, make a pretty variety in the stove amongst other exotic plants.

The second sort is supposed to be the Anacardium Orientale; but whether this is the true sort, I cannot determine, having seen only the seeds of that plant, which are frequently brought to Europe for marking nuts; and those have been too old to grow, so I cannot take upon me to determine how far Mr. Jacquin is right.

BONUS HENRICUS. See CHENOPODIUM.
BORBONIA. Lin. Gen. Plant. 764.

The CHARACTERS are,

It hath a turbinated empalement of one leaf, cut at the top into five acute segments, which are stiff, pungent, and about half the length of the petals. The flower hath five leaves, and is of the butterfly shape. The standard is obtuse and reflexed. The wings are heart-shaped and shorter than the standard. The keel hath obtuse lunulated leaves. It hath nine stamina joined in a cylinder, and one upper standing single, turning up its point. These have small summits. In the center is situated an awl-shaped germen, supporting a short style, crowned by an obtuse indented stigma. The germen afterward becomes a round pointed pod terminated with a spine, having one cell, inclosing a kidney-shaped seed.

This genus of plants is ranged in the third order of Linnaeus's seventeenth class, intitled Diadelphia Decandria, the flower having ten stamina, nine of which are joined, and the other stands separate.

The SPECIES are,

1. BORBONIA (*Lanceolata*) foliis lanceolatis multinerviis integerrimis. Lin. Sp. Plant. 707. Borbonia with entire spear-shaped leaves having many nerves. Genista Africana frutescens rusci nervosis foliis. Raii Hist. 3. 107.

2. BORBONIA (*Cordata*) foliis cordatis multinerviis integerrimis. Lin. Sp. Plant. 737. Borbonia with entire heart-shaped leaves having many nerves. Spartium Africanum frutescens rusci folio caulem amplexante. Com. Hort. Amst. 2. 195.

3. BORBONIA (*Trinervia*) foliis lanceolatis trinerviis integerrimis. Lin. Sp. Plant. 707. Borbonia with entire spear-shaped leaves, having three veins.

These plants grow naturally at the Cape of Good Hope, from whence I received their seeds. In the natural place of their growth, they rise to the height of ten or twelve feet; but in Europe they seldom are more than four or five, having slender stems divided into several branches, which are garnished with stiff leaves, placed alternately; those of the first sort are narrow, long, and end in a sharp point. The flowers come out from between the leaves at the end of the branches in small clusters; these are yellow, and shaped like those of the Broom. It flowers in August and September, but doth not perfect seeds in England.

The second sort hath broader leaves than the first: the stalks of this are slender, covered with white bark. The leaves embrace these at their base, where they are broadest, and are terminated by sharp points like those of Kneeholm, or Butchers Broom. The flowers are produced in small clusters at the end of the branches, which are the same shape and colour as those of the former, but larger. This flowers at the same time with the former, but never produces seeds here.

The third sort hath stronger stalks than either of the former, garnished almost their whole length, as are also the branches with stiff spear-shaped leaves, having three longitudinal nerves on each; these are placed closer together than those of the other species. The flowers are produced at the extremity of the branches, each standing on a separate foot-stalk: they are of the same shape and colour with the former, but larger.

As these plants do not perfect their seeds in this country, they are with difficulty propagated here. The only method by which I have yet succeeded, hath been by laying down their young shoots; but these are commonly two years before they put out roots fit to be separated from the old plant. In laying of these down, the joint which is laid in the ground should be slit upward, as is practised in laying Carnations, and the bark of the tongue at bottom taken off. The best time to lay these down, is in the beginning of September; and the shoots most proper for this purpose, are those which come out immediately, or very near the root, and are of the same year's growth, not only from their situation being near the ground, and thereby better adapted for laying, but these are also more apt to put out roots than any of the upper branches.

But where good seeds can be procured, that is the more eligible method of propagating the plants; for those raised from the seeds make the straightest plants, and are quicker of growth. When good seeds are obtained, they should be sown in pots filled with light loamy earth; as soon as they are received; which, if it happens in the autumn, the pots should be plunged into an old bed of tanners bark, under a frame, where they may remain all the winter, being careful that they are secured from frost, and have not much wet. In the spring, the pots should be plunged into a hot-bed, which will bring up the plants in five or six weeks. When these are fit to remove, they should be each planted into a separate small pot, filled with the like loamy earth, and plunged into a moderate hot-bed, observing to shade them until they have taken fresh root, as also to refresh them with water, as they may require it. After this they must by degrees be inured to the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy the air and sun; during the winter

winter season, these plants must be sparingly watered; but in summer, when they are placed abroad, they will require to be frequently refreshed, but must not have too much water given them each time.

These plants make a pretty variety in the green-house in winter, and as they do not require any artificial heat to preserve them, they are worthy of a place in every garden where there is conveniency for keeping them.

BORDERS. The use of these in a garden, is to bound and inclose parterres, to prevent them being injured by walking in them: these are commonly rendered very ornamental by means of the flowers, shrubs, &c. that are planted in them.

These ought to be laid with a rising in the middle, because, if they are flat, they are not agreeable to the eye.

As for their breadth, five or six feet are often allowed for the largest, and four for the lesser.

Borders are of four sorts: those are the most common, that are continued about parterres without any interruption, and are wrought with a gentle rising in the middle, like an ass's back, and planted with flowers.

The second sort of borders is such as are cut into compartments, at convenient distances, by small passages; and being also raised in the middle, as before-mentioned, are likewise set off with flowers.

The third sort is such as are laid even and flat without flowers, having only a verge of grass in the middle, being edged with two small paths, raked smooth and fanded. These are sometimes garnished with flowering shrubs, and flowers of large growth, or with vases and flower-pots, placed regularly along the middle of the verge of grass.

The fourth sort is quite plain, and only fanded, as in the parterres of orangery, and is filled with cases ranged in a regular order along those borders which are edged with Box on the sides next to the walks; and on the other, with verges and grass-work next the parterre.

Borders are either made strait, circular, or in cants, and are turned into knots, scrolls, and other compartments.

Florists also make borders either along walks, or detached, and in these they raise their finest and choicest flowers. These are frequently encompassed with border-boards painted green, which make them look exceeding neat.

But, in large parterres, this is not to be expected; since, if they be stocked with flowers succeeding one another in their several seasons, it is sufficient, so that nothing appears bare and naked.

It is usual to discontinue the borders at the ends next to the house, that the embroidery and rise of the parterre may not be hidden by the shrubs and flowering plants, and that the design may be better judged of.

Since the modern way of gardening has been introduced in England, all the French taste of parterres, scroll-borders, and fret-work in Box, has been justly banished our gardens: therefore I have only mentioned them here, to expose the taste of those architect-gardeners, who have no idea of the noble simplicity of an open lawn of grass, properly bounded by plantations; but, instead of this, divide the part of the garden near the house, into various forms of borders edged with Box, with sand, shell, or gravel-walks leading about them, by which the ground is cut into many angles, scrolls, &c. which is very hurtful to the eyes of a judicious person: therefore, where flowers are desired, there may be borders continued round the extent of the lawn, immediately before the plantations of shrubs; which, if properly planted with hardy flowers to succeed each other, will afford a much more pleasing prospect than the stiff borders made in scrolls and compartments, after the French manner, can possibly do.

These borders may be made six or eight feet wide, in proportion to the extent of the garden and size of

the lawn: for a small lawn should not have very broad borders, nor ought a large lawn to be bounded by small borders; so that a due proportion should be always observed in the laying out of gardens.

BORRAGO [or Borage, which signifies much the same as courage, because it is a good raiser of the spirits.] Borage.

The CHARACTERS are,

The empalement is divided into five parts at the top, and is permanent. The flower is of one leaf, having a short tube, spread wide open above, being divided into five acute segments at the brim. The chaps of the flower are crowned by five prominences, which are obtuse and indented. It hath five stamina which are joined together, crowned by oblong summits. It hath four germen situated in the center, and a single style longer than the stamina, supporting a single stigma. The four germen afterward become so many roundish rough seeds, inserted in the cavities of the receptacle, and included in the large swollen empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and a single style.

The SPECIES are,

1. **BORRAGO (Officinalis)** foliis omnibus alternis, calycibus patentibus. Hort. Upsal. 34. Borage with all the leaves growing alternate, and a spreading flower-cup. *Borrigo floribus cæruleis.* J. B.
2. **BORRAGO (Orientalis)** calycibus tubo corollæ brevioribus, foliis cordatis. Hort. Cliff. 45. Borage with a flower-cup shorter than the tube of the flower, and heart-shaped leaves. *Borrigo Constantinopolitana flore reflexo cæruleo calyce vesicæreo.* Tourn. Cor. 6.
3. **BORRAGO (Africana)** foliis ramificationum oppositis petiolatis, calycinis foliolis ovatis acutis erectis. Lin. Sp. 197. African Borage with leaves growing opposite to the branches upon foot-stalks, and the leaves of the empalement oval, pointed, and erect. *Cynoglossum Boraginifolio & facie Æthiopicum.* Pluk. Alm.
4. **BORRAGO (Indica)** foliis ramificationum oppositis calycinis foliolis sagittatis. Lin. Sp. Plant. 137. Borage with opposite leaves on the branches, and spear-shaped leaves to the flower-cup. *Cynoglossoides folio caulem amplexante.* Inard. Act. Scien. 1718.

The first is the common Borage, whose flowers are used in medicine, and the herb for cool tankards in summer. Of this there are three varieties, which generally retain their difference from seeds; one hath a blue, the other a white, and another a red flower; and there is one which hath variegated leaves. These variations have continued several years in the Chelsea garden, with very little alteration; but as they do not differ in any other respect from the common, I have only mentioned them as varieties.

This is an annual plant, which, if permitted to scatter its seeds, the plants will come up in plenty without care; the seeds may also be sown either in spring or autumn, but the latter season is preferable, on a spot of open ground where the plants are designed to remain; when the plants have obtained a little strength, the ground should be hoed to destroy the weeds, and the plants must be cut up where they are too near each other, leaving them eight or ten inches asunder. After this they will require no farther care, unless the weeds should come up again; then the ground should be a second time hoed over to destroy them, which, if well performed, and in dry weather, will clear the ground from weeds, so it will require no more cleaning till the Borage is decayed. The plants which are raised in the autumn, will flower in May, but those which are raised in the spring, will not flower till June; so that where a continuation of the flowers are required, there should be a second sowing in the spring, about a month after the first; but this should be on a shady border, and if the season should prove dry, the ground must be watered frequently, to bring up the plants; this latter sowing will continue flowering till the end of summer.

B O S

The second sort was brought from Constantinople, where it grows naturally. This is a perennial plant, having thick fleshy roots, which spread under the surface of the ground, and is thereby propagated with great facility. This sends out many oblong heart-shaped leaves from the root, without any order, having long hairy foot-stalks; from the root arises the flower-stem, which is more than two feet high when fully grown, having at the joints a single small leaf without a foot-stalk. The upper part of the stalk branches out into several small foot-stalks, which are terminated by loose panicles of flowers; these are of a pale blue colour, and the petal is reflexed backward, so that the connected stamina and style are left naked. After the flowers are fallen, the four germen become so many rough seeds, smaller than those of the common Borage. It flowers in March, and the seeds ripen in May. When the flower-stalk first appears, the flowers seem collected into a close spike, some of which often spread open before the stalk is six inches high; but as the stalks advance, they divide into many loose spikes.

It is easily propagated by the root, which may be parted in the autumn: these should have a dry soil and a warm situation, for as the flower-stalks appear early in the spring, so when they are much exposed, they are often killed by the frost, and thereby prevented flowering; if these plants are planted in dry rubbish, they will not grow too luxuriant, so will not be in danger of suffering by frost. Some of the seeds of this have scattered into the joints of an old wall in the Chelsea garden, where the plants have grown without care for some years, and are never injured by cold or heat.

The third and fourth sorts grow naturally in Africa; these are both annual plants, which rarely rise a foot high, having rough stalks; those of the third sort are set on by pairs opposite, with short foot-stalks, but the leaves of the fourth closely embrace the stalks at their base; the flowers come out on short foot-stalks from the wings of the leaves, and also at the top of the stalks. Those of the third sort are white, and those of the fourth a pale flesh colour; but neither of them make any great appearance, so are seldom cultivated but in botanic gardens for variety.

The seeds of these plants should be sown upon a hot-bed in March, and when the plants are strong enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a new hot-bed to bring them forward, otherwise they will not perfect their seeds in this country; but in hot weather they must have a great share of air, otherwise they will draw up weak, and fail before the seeds are ripe.

BOSEA, Yervamora, or Shrubby Golden-rod.

The CHARACTERS are,

It hath an empalement composed of five roundish, concave, equal leaves; it hath no corolla, but five awl-shaped stamina longer than the empalement, terminated by single summits; and an oblong, oval, pointed germen, with two stigma sitting close upon it. The empalement afterward becomes a globular berry with one cell, inclosing one roundish seed.

This genus of plants is ranged in the second section of Linnaeus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

We have but one SPECIES of this plant, viz.

BOSEA. (*Yervamora*.) Lin. Hort. Cliff. 84. Arbor baccifera Canariensis, syringiae caeruleae foliis, purpurantibus venis, fructu monopyreno Yervamora Hispanorum. Pluk. Phyt. Commonly called Golden-rod-tree.

This plant is a native of the islands of the Canaries, and it hath also been since found in some of the British islands in America; but was first brought into England from the Canaries, and has been long an inhabitant of the English gardens; but I have not as yet seen any of these plants in flower, though I have had many old plants under my care more than forty years: it makes a pretty strong woody shrub, growing

B R A

with a stem as large as a middling person's leg; the branches come out very irregular, and make considerable shoots in summer, which should be shortened every spring, to preserve the heads of the plants in any tolerable order: these branches retain their leaves till toward the spring, when they fall away, and new leaves are produced soon after: it may be propagated by cuttings planted in the spring, and the plants must be housed in winter, being too tender to live in the open air through the year, in this country.

BOSQUETS are little groves; so called from Boschetto, Italian, which is a diminutive of Bosco, a wood or grove.

These are small compartments in gardens, which are formed of trees, shrubs, or tall large growing plants, planted in quarters; and are either disposed regularly in rows, or in a more wild or accidental manner, according to the fancy of the owner: these quarters are commonly surrounded with Evergreen hedges, and the entrance formed into regular porticos with Yews, which are by far the best and most useful trees for this purpose. In the inside of these quarters may be made some walks, either strait or winding; which, if the quarters are large, should be five or six feet broad, and may be laid with turf, and kept well mowed and rolled, which will render the walking much easier and pleasanter than if the walks are only the common earth; which in smaller quarters cannot be otherwise, for if the trees are close, and the walks narrow, so as to be shaded and over-hung by the trees, the grass will not grow.

These quarters may be also surrounded with hedges of Lime, Elm, Hornbeam, or Beech; which should be kept well sheared, and not suffered to rise too high; that the heads of the trees may be fully seen over them, and the stems only hid from the sight, when in the walks on the outside of the quarters.

In the planting of these bosquets, you should observe to mix the trees, which produce their leaves of different shapes, and various shades of green, and hoary or mealy leaves, so as to afford an agreeable prospect: besides, there is a great variety of different fruits, which these trees produce in autumn; which, altho' of little or no use, that we know of, yet have a very good effect, in affording an agreeable variety for some time after the leaves are gone; as the Euonymus, or Spindle-tree, the Opulus, or Marsh Elder, the Cockspur Hawthorn, with many other sorts, too numerous to mention in this place; whose berries afford food for the birds, so that they will be thereby invited to stay and harbour in these little groves, which by their different notes, will render these places very agreeable in the spring. But I would advise never to mix Evergreens with deciduous trees; for, besides the ill effect it hath to the sight (especially in winter,) they seldom thrive well together; so that those quarters where you intend to have Evergreens, should be wholly planted therewith; and in the other parts mix as many varieties of different trees, which cast their leaves, as you can conveniently; and also plant some of the largest growing flowers (especially near the outside of the quarters,) which will add greatly to the variety, if they have but air enough to grow; but if any of the Evergreen trees are mixed with the deciduous, it should be only to border the wood.

These bosquets are proper only for spacious gardens, being expensive in their first making, as also in keeping.

BOTRYS. See CHENOPodium.

BOX-TREE. See BUXUS.

BRABEJUM, African Almond, vulgò.

The CHARACTERS are,

The flower hath no empalement; it is composed of four narrow obtuse petals which are erect, forming a tube, but are turned backward at top; it hath four slender stamina which are inserted in the bottom of the petals, and are of the same length, having small summits. In the center is a small hairy germen, supporting a slender style, crowned by a single stigma; the germen afterward becomes an oval, hairy, dry berry, inclosing an oval nut.

This

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

We have but one SPECIES of this plant, viz.

BRABEJUM. (*Stellatifolium*.) Hort. Cliff. Amygdalus Æthiopica, fructu holoserico. Breyn. Cent. *African, or Ethiopian Almond*.

This tree is a native of the country about the Cape of Good Hope.

In Europe it seldom grows above eight or nine feet high, but in its native soil it is a tree of middling growth; but as it must be kept in pots, or tubs, being too tender to live through the winter in the open air, so we cannot expect to see it grow to a great size. It rises with an upright stem, which is soft, and full of pith within, covered with a brown bark. From the stem are sent out horizontal branches at every joint, the lower being the longest, and every tier diminishing to the top, so as to form a sort of pyramid. The branches are garnished with leaves at each joint, which are from four to five inches long, and half an inch broad in the middle, of a deep green on their upper side, but of a pale russet colour on their under, indented on their edges, standing on very short foot-stalks. The flowers are produced toward the end of the shoots, coming out from between the leaves quite round the branches, which are of a pale colour, inclining to white; these appear early in the spring, and fall away without any fruit succeeding them in this country.

This plant is, with difficulty, propagated by layers; being often two years before they make roots strong enough to be taken from the old plants; when the branches are laid down, it will be a good method to slit them at a joint (as is practised in laying Carnations) which will promote their taking root.

These must have but little water given them, especially in winter, for as the young shoots are chiefly pith within, so they are very subject to rot with much moisture. The best time to make the layers is in April, just as the plants are beginning to shoot; the layers must always be made of the former year's shoots. As this plant is very difficult to propagate, so it is very scarce in Europe, there being very few in the Dutch gardens at present.

The plants must have a good green-house in winter, but in summer should be set abroad in a sheltered situation, where they will thrive, and annually produce flowers in the spring, so will make a pretty variety among other exotic plants in the green-house.

BRANCA URSINA. See ACANTHUS.

BRASSICA, the Cabbage.

The CHARACTERS are,

The empalement is composed of four upright, spear-shaped, small leaves, which are convex at their base, and fall off. The flower is cross-shaped, having four oval plain petals, which spread open, and are entire. It hath four oval nectarious glands, one being situated on each side of the short stamina and pointal, and one on each side the empalement. It hath six stamina, which are awl-shaped and erect, two of which are opposite, and the length of the empalement, the other four are longer; these have erect pointed summits. It hath a taper germen the length of the stamina, having a short style thicker than the germen, and crowned by an entire stigma. The germen afterward becomes a long taper pod, depressed on each side, and is terminated by the apex of the intermediate partition, which divides it into two cells, filled with round seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradyamia Siliquosa, the flowers having four long and two short stamina, and are succeeded by long pods.

I shall first enumerate the species, which are distinct, and afterward mention the varieties, which are cultivated for the table; for although most of these may be continued distinct by proper care, without alteration; yet as they are liable to vary when planted near each other for seeds, so we must not admit of their being different species. To this genus Dr. Linnæus

has joined the Turnep, Navew, and Rocket, which by their generical characters, may in a system of botany, come under the same title; but in a treatise of gardening, it may occasion confusion; therefore I shall treat of them under their former titles, by which they are generally known.

The SPECIES are,

1. BRASSICA (*Oleracea*) radice caulescente tereti carnosa. Hort. Cliff. 338. *Cabbage with a taper fleshy stalk*. Brassica capitata alba. C. B. P. 111. *The common white Cabbage*.
2. BRASSICA (*Napobrassica*) radice caulescente orbiculari carnosa, foliis sessilibus. *Cabbage with a round fleshy stalk, and leaves growing close to the stalks*. Brassica radice napiformi. Tourn. Inst. R. H. 219. *Turnep-rooted Cabbage*.
3. BRASSICA (*Botrytis*) radice caulescente tereti carnosa, floralibus multicaulis. *Cabbage with a taper fleshy stalk at the root, and many branching flower-stalks*. This is the Brassica Cauliflora. Casp. Bauh. Pin. 111. *The Cauliflower*.
4. BRASSICA (*Sylvestris*) radice cauleque tenui ramoso perenni foliis alternis marginibus incis. *Cabbage with a branching perennial stalk and root, and leaves growing alternate, which are cut on their edges*. Brassica maritima arborea sive procerior ramosa. Mor. Hist. 2. p. 208. *Taller shrubby Sea Cabbage*.
5. BRASSICA (*Violacea*) foliis lanceolato-ovatis glabris indivisis dentatis. Hort. Upf. 191. *Cabbage with entire, oval, spear-shaped, smooth leaves, which are indented*.
6. BRASSICA (*Purpurea*) foliis oblongo-cordatis amplexicaulibus, integerrimis. *Cabbage with oblong heart-shaped leaves embracing the stalks, which are entire*. Brassica campestris perfoliata flore purpureo. C. B. P. 112.
7. BRASSICA (*Orientalis*) foliis cordatis amplexicaulibus glabris. Lin. Sp. 931. *Colewort with heart-shaped smooth leaves which embrace the stalk*. Brassica Orientalis perfoliata flore albo siliqua quadrangula. Tourn. Cor. 16.
8. BRASSICA (*Gongylodes*) radice caulescente tereti, foliis inferioribus petiolatis superioribus semiamplexicaulibus. *Cabbage with a taper stalk, the under leaves with foot-stalks, and the upper half embracing the stalk*. Napus Sylvestris. C. B. P. 95. *The wild Navew, or Cole Seed*.

The VARIETIES of the first sort are,

1. BRASSICA (*Sabauda*) sabauda hyberna. Lob. Icon. *The Savoy Cabbage, commonly called Savoy*.
2. BRASSICA (*Rubra*) capitata rubra. C. B. P. 111. *The Red Cabbage*.
3. BRASSICA (*Pyramidalis*) capitata alba pyramidalis. *The Sugar-loaf Cabbage*.
4. BRASSICA (*Præcox*) capitata alba præcox. *The early Cabbage*.
5. BRASSICA (*Peregrina*) peregrina moschum olens. H. R. Par. *Foreign Musk Cabbage*.
6. BRASSICA (*Muscovitica*) capitata alba minor Muscovitica. H. A. *Small Russia Cabbage*.
7. BRASSICA (*Capitata*) capitata alba compressa. Boerh. Ind. alt. 11. *The large sided Cabbage*.
8. BRASSICA (*Viridis*) capitata viridis sabauda. Boerh. Ind. 11. *The green Savoy*.
9. BRASSICA (*Laciniata*) fimbriata. C. B. P. 111. *The Borecole*.
10. BRASSICA (*Selenisia*) fimbriata virescens. Boerh. Ind. 2. 12. *Green Borecole*.
11. BRASSICA (*Fimbriata*) fimbriata Siberica. Boerh. Ind. 2. 12. *Siberian Borecole, called by some Scotch Kale*.

The second sort is undoubtedly a distinct species, for I have always found the seeds produce the same, with this difference only, that in good ground the stalks will be much larger than in poor land.

The VARIETIES of the third sort are,

1. BRASSICA Italica purpurea Broccoli dicta. Juss. *Purple Broccoli*.
2. BRASSICA Italica alba Broccoli dicta. Juss. *White Broccoli*.

The second sort, I believe, never varies, for I have cultivated it many years, and have not found it to alter.

alter. This grows naturally on the sea-shore, near Dover. It hath a perennial branching stalk, in which it differs from all the other species. I have continued these three or four years, and have eaten the young shoots after they had been much frozen, when they were very sweet and good; but at other times they are very strong and stringy. In very severe winters, when the other sorts are destroyed, this is a necessary plant, for the most severe frosts do not injure it. The leaves of this are inclining to a purple colour, and are placed alternately on the branches. The flower-stalks grow from the end of the branches, and spread out horizontally; but those which arise from the center of the plants, grow erect, and seldom put out branches.

The third sort, which is the Cauliflower, has been supposed a variety of the common Cabbage; but from more than fifty years experience in cultivating these plants, I could never find the least appearance of either species approaching each other; and they are so different in their leaves, as to be easily distinguished by persons of skill, when the plants are young. But there is one essential difference between them in their flower-stems; for the common Cabbage puts out one upright stem from the center of the Cabbage, which afterward divides into several branches, whereas the Cauliflower sends out many flower-stems from the part which is eaten; which is only a compact collection of the heads of these stalks, which afterward divides into so many stems, branching out into many spreading shoots, so as to form a large spreading head when in flower, but never rises pyramidically like the Cabbage.

The two sorts of Broccoli I take to be only varieties of the Cauliflower, for although these may with care be kept distinct, yet I doubt, if they were to stand near each other for seeds, if they would not intermix; and I am the rather inclined to believe this, from the various changes which I have observed in all these sorts; for I have frequently had Cauliflowers of a green colour, with flower-buds regularly formed at the ends of the shoots, as those of Broccoli, though the colour was different; and the white Broccoli approaches so near to the Cauliflower, as to be with difficulty distinguished from it; yet when these are cultivated with care, and never suffered to stand near each other, when left to produce seeds, they may be kept very distinct in the same garden; for the variations of these plants is not occasioned from the soil, but the mixing of the farina of the flowers with each other, where they are planted near together; therefore those persons who are curious to preserve the several varieties distinct, should never suffer the different kinds to stand near each other for seed.

The Cauliflower was first brought to England from the island of Cyprus, where I have been informed they are in very great perfection at present: but it is supposed, they were originally brought thither from some other country: most of the old writers mention it to have been brought from that island, to the different parts of Europe, so that from thence all the gardens in Europe have been supplied; and although this plant was cultivated in a few English gardens long since, yet it was not brought to any degree of perfection, till about 1680, at least not to be sold in the markets; and since the year 1700, they have been so much improved in England, as that such of them as before were greatly admired, would at present be little regarded.

This plant has been much more improved in England, than in any other parts of Europe. In France they rarely have Cauliflowers till near Michaelmas, and Holland is generally supplied with them from England. In many parts of Germany there was none of them cultivated till within a few years past; and most parts of Europe are supplied with seeds from hence.

The eighth sort, which is generally known by the title of Rape or Cole Seed, is much cultivated in the Isle of Ely, and some other parts of England for its

seed, from which the Rape Oil is drawn; and it hath also been cultivated of late years in other places, for feeding of cattle, to great advantage. This hath been lately joined to the *Napus Sativa*, or Garden Navew, supposing them to be the same species; but I have cultivated both sorts more than twenty years, and could never observe either of them to vary; indeed the whole appearance of the plants, is sufficient to determine them as distinct species; but as the Garden Navew approaches nearer the Turnep than the Cabbage, so I shall treat of that under the title of *RAPA*.

The Cole Seed, when cultivated for feeding of cattle, should be sown about the middle of June. The ground for this should be prepared in the same manner as for Turneps. The quantity of seeds for an acre of land, is from six to eight pounds, and as the price of the seeds is not great, so it is better to allow eight pounds; for if the plants are too close in any part, they may be easily thinned when the ground is hoed. When the plants have put out six leaves, they will be fit to hoe, which must be performed in the same manner as is practised for Turneps, with this difference only, of leaving these much nearer together; for as they have fibrous roots and slender stalks, so they do not require near so much room. These plants should have a second hoeing, about five or six weeks after the first, which, if well performed in dry weather, will entirely destroy the weeds, so they will require no farther culture. By the middle of November these will be grown large enough for feeding, when, if there is a scarcity of fodder, this may be either cut or fed down; but where there is not an immediate want of food, it had better be kept as a reserve for hard weather, or spring feed, when there may be a scarcity of other green food. If the heads are cut off, and the stalks left in the ground, they will shoot again early in the spring, and produce a good second crop in April, which may be either fed off, or permitted to run to seeds, as is the practice where this is cultivated for the seeds: but if the first is fed down, there should be care taken that the cattle do not destroy their stems, or pull them out of the ground. As this plant is so hardy as not to be destroyed by frost, so it is of great service in hard winters for feeding of ewes; for when the ground is so hard frozen, as that Turneps cannot be taken up, these plants may be cut off for a constant supply. In several places where I have sown this seed, I have found that one acre of land will produce as much food, as almost two acres of Turneps; and this will afford late food after the Turneps are run to seed; and if it is afterward permitted to stand for seed, one acre will produce as much as, at a moderate computation, will sell for five pounds, clear of charges.

Partridges, pheasants, turkeys, and most other fowl, are very fond of this plant; so that wherever it is cultivated, if there are any birds in the neighbourhood, they will constantly lie among these plants.

The seeds of this plant are sown in gardens for winter and spring fallads, this being one of the small fallad-herbs.

The common white, red, flat, and long-sided Cabbages are chiefly cultivated for winter use: the seeds of these sorts must be sown the end of March, or beginning of April, in beds of good fresh earth; and in May, when the young plants will have about eight leaves, they should be pricked out into shady borders, about three inches square, that they may acquire strength, and to prevent their growing long shanked.

About the beginning of June you must transplant them out, where they are to remain for good (which in the kitchen-gardens near London, is commonly between Cauliflowers, Artichokes, &c. at about two feet and a half distance in the rows;) but if they are planted for a full crop in a clear spot of ground, the distance from row to row should be three feet and a half, and in the rows two feet and a half asunder: if the season should prove dry when they are transplanted out,

out, you must water them every other evening, until they have taken fresh root; and afterwards, as the plants advance in height, you should draw the earth about their stems with a hoe, which will keep the earth moist about their roots, and greatly strengthen the plants: you must also observe to keep them clear from weeds, which are apt to draw the plants up tall (if suffered to grow amongst them,) and often spoil them.

These Cabbages will some of them be fit for use soon after Michaelmas, and will continue until the end of February, if they are not destroyed by bad weather; to prevent which, the gardeners near London pull up their Cabbages in November, and trench their ground up in ridges, laying their Cabbages against their ridges as close as possible on one side, burying their stems in the ground: in this manner they let them remain till after Christmas, when they cut them for the market; and although the outer part of the Cabbage be decayed (as is often the case in very wet or hard winters,) yet, if the Cabbages were large and hard when laid, the inside will remain sound.

The Russian Cabbage was formerly in much greater esteem than at present, it being now only to be found in particular gentlemen's gardens, who cultivate it for their own use, and is rarely ever brought to the market. This must be sown late in the spring of the year, and managed as those before directed; with this difference only, that these must be sooner planted out for good, and must have an open clear spot of ground, and require much less distance every way; for it is but a very small hard Cabbage. These will be fit for use in July or August, but will not continue long before they will break, and run up to seed. The best method to have these Cabbages good, is to procure fresh seeds from abroad every year, for it is apt to degenerate in England in a few years.

The early and Sugar-loaf Cabbages are commonly sown for summer use, and are what the gardeners about London commonly call Michaelmas Cabbages. The season for sowing of these is about the end of July, or beginning of August, in an open spot of ground; and when the plants have got eight leaves, you must prick them into beds at about three inches distance every way, that the plants may grow strong and short shanked; and in the middle of October you should plant them out for good; the distance that these require is, three feet row from row, and two feet and a half asunder in the rows. The gardeners near London commonly plant these Cabbages upon the same spot of ground, where their winter Spinach is sown; so that when the Spinach is cleared off in the spring, the ground will have a crop of Cabbages upon it; you must therefore clear off the Spinach just round each plant early in the spring, that with a hoe you may draw the earth up to the stem; and when all your Spinach is cleared off, which is commonly in the beginning of April, you must hoe down all the weeds, and draw up the earth again about your Cabbage plants.

In May, if your plants were of the early kind, they will turn in their leaves for cabbaging; at which time, the gardeners near London, in order to obtain them a little sooner, tie in their leaves close with a slender Osier-twigg to blanch their middle; by which means, they have them at least a fortnight sooner than they could have if they were left untied.

The early Cabbage being the first, we should choose (if for a gentleman's use) to plant the fewer of them, and a greater quantity of the Sugar-loaf kind, which comes after them; for the early kind will not supply the kitchen long, generally cabbaging apace when they begin, and as soon grow hard, and burst open; but the Sugar-loaf kind is longer before it comes, and is as slow in its cabbaging; and, being of an hollow kind, will continue good for a long time. I have known a large quarter of ground, which was planted with this sort of Cabbage for market use, which hath afforded a supply for near three months together. This, though of singular service to a gen-

tleman's garden, is not so much for the advantage of the market gardener, who loves to have his ground cleared sooner, that he may have another crop upon it, of Celery, Endive, &c. which is more to his purpose; for they, paying large rents for their land, are obliged to have as many crops in a year as possible.

Although I before have advised the planting out of Cabbages for good in October, yet the Sugar-loaf kind may be planted out in February, and will succeed as well as if planted earlier, with this difference only, that they will be later before they cabbage. You should also reserve some plants of the early kind in some well-sheltered spot of ground, to supply your plantation, in case of a defect; for in mild winters many of the plants are apt to run to seed, especially when their seeds are sown too early, and in severe winters they are often destroyed.

The Savoy Cabbages are propagated for winter use, as being generally esteemed the better when pinched by the frost: these must be sown about the middle of April, and treated after the manner as was directed for the common white Cabbage; with this difference, that these may be planted at a closer distance than those; two feet and a half square will be sufficient. These are always much better when planted in an open situation, which is clear from trees and hedges; for in close places they are very subject to be eaten almost up by caterpillars, and other vermin, especially if the autumn prove dry.

The Borecole may be also treated in the same manner, but need not be planted above one foot, asunder in the rows, and the rows two feet distance: these are never eaten till the frost hath rendered them tender, for otherwise they are tough and bitter.

The seeds of the Broccoli, (of which there are several kinds, viz. the Roman, or purple, and the Neapolitan, or white, and the black Broccoli, with some others; but the Roman is chiefly preferred to them all) should be sown about the latter end of May, or beginning of June, in a moist soil; and when the plants are grown to have eight leaves, transplant them into beds (as was directed for the common Cabbage;) and toward the middle of July they will be fit to plant out for good, which should be into some well sheltered spot of ground, but not under the drip of trees: the distance these require is about a foot and a half in the rows, and two feet row from row. The soil, in which they should be planted, ought to be rather light than heavy, such as are the kitchen gardens near London: if your plants succeed well (as there will be little reason to doubt, unless the winter prove extreme hard,) they will begin to shew their small heads, which are somewhat like a Cauliflower, but of a purple colour, about the end of December, and will continue eatable till the middle of April.

The brown or black Broccoli is by many persons greatly esteemed, though it doth not deserve a place in the kitchen-garden, where the Roman Broccoli can be obtained, which is much sweeter, and will continue longer in season: indeed, the brown sort is much hardier, so that it will thrive in the coldest situations, where the Roman Broccoli is sometimes destroyed in very hard winters. The brown sort should be sown in the middle of May, and managed as hath been directed for the common Cabbage, and should be planted at the same distance (which is about two feet and a half asunder.) This will grow very tall, so should have the earth drawn up to their stems as they advance in height. This doth not form heads so perfect as the Roman Broccoli; the stems and hearts of the plants are the parts which are eaten.

The Roman Broccoli (if well managed) will have large heads, which appear in the center of the plants, like clusters of buds. These heads should be cut before they run up to seed, with about four or five inches of the stem; the skin of these stems should be stripped off, before they are boiled: these will be

very tender and little inferior to Asparagus. After the first heads are cut off, there will be a great number of side shoots produced from the stems, which will have small heads to them, but are full as well flavoured as the large. These shoots will continue good until the middle of April, when the Asparagus will come in plenty to supply the table.

The Naples Broccoli hath white heads, very like those of the Cauliflower, and eats so like it, as not to be distinguished from it. This is much tenderer than the Roman Broccoli, so is not so much cultivated in England; for as the gardens near London generally produce great plenty of late Cauliflowers, which, if the season prove favourable, will continue till Christmas, the Naples Broccoli, coming at the same time, is not so valuable.

Besides this first crop of Broccoli (which is usually sown the end of May,) it will be proper to sow another crop the beginning of July, which will come in to supply the table the latter end of March, and the beginning of April, and being very young, will be extremely tender and sweet.

In order to save good seeds of this kind of Broccoli in England, you should reserve a few of the largest heads of the first crop, which should be let remain to run up to seed, and all the under shoots should be constantly stripped off, leaving only the main stem to flower and seed. If this be duly observed, and no other sort of Cabbage permitted to seed near them, the seeds will be as good as those procured from abroad, and the sort may be preserved in perfection many years.

The manner of preparing the Naples Broccoli for the table is this: when your heads are grown to their full bigness (as may be easily known by their dividing, and beginning to run up,) then you should cut them off, with about four inches of the tender stem to them; then strip off the outer skin of the stem, and after having washed them, boil them in a clean linen cloth (as is practised for Cauliflowers,) and serve them up with butter, &c. and, if they are of a right kind, they will be tenderer than any Cauliflowers, though very like them in taste.

The Turnep-rooted Cabbage was formerly more cultivated in England than at present, for since other sorts have been introduced which are much better flavoured, this sort has been neglected. There are some persons who esteem this kind for soups; but it is generally too strong for most English palates, and is seldom good but in hard winters, which will render it tender and less strong.

It may be propagated by sowing the seeds in April, on a bed of light fresh earth; and when the plants are come up about an inch high, they should be transplanted out in a shady border, at about two inches distance every way, observing to water them until they have taken root; after which time they will require no other culture but to keep them clear from weeds, unless the season should prove extremely dry; in which case it will be proper to water them every four or five days, to prevent their being stunted by the mildew, which is subject to seize these plants in very dry weather.

In the beginning of June, the plants should be transplanted out where they are to remain, allowing them two feet distance every way, observing to water them until they have taken root; and as their stems advance, the earth should be drawn up to them with a hoe, which will preserve a moisture about their roots, and prevent their stems from drying and growing woody, so that the plants will grow more freely; but it should not be drawn very high, for as it is the globular part of the stalk which is eaten, so that should not be covered. In winter they will be fit for use, when they should be cut off, and the stalks pulled out of the ground, and thrown away, as being good for nothing after the stems are cut off.

The curled Colewort of Siberian Borecole, is now more generally esteemed than the former, being extreme hardy; so is never injured by cold, but is always

sweeter in severe winters than in mild seasons. This may be propagated by sowing the seeds the beginning of July; and when the plants are strong enough for transplanting, they should be planted in rows about a foot and a half asunder, and ten inches distance in the rows; this work should be performed at a moist time, when the plants will soon take root, and require no farther care. These will be fit for use after Christmas, and continue good until April, so that they are very useful in a family.

The Musk Cabbage has, through negligence, been almost lost in England, though for eating it is one of the best kinds we have; but being tenderer than many other sorts, is not profitable for gardeners who supply the markets; but those who cultivate them for their own table, should make choice of this, rather than any of the common Cabbage, for it is always looser, and the leaves more crisp and tender, and has a most agreeable musky scent when cut. This may be propagated in the same manner as the common Cabbage, and should be allowed the same distance. It will be fit for use in October, November, and December; but, if the winter proves hard, these will be destroyed much sooner than the common sort.

The common Colewort, or Dorsetshire Kale, is now almost lost near London, where the markets are usually supplied with Cabbage plants, instead of them; and these being tenderer, and more delicate in winter, are much more cultivated than the common Colewort, which is better able to resist the cold in severe winters than those, but is not near so delicate till pinched by frost. And since the winters in England have been generally temperate of late years, the common Cabbage plants have constantly been cultivated by the gardeners near London, and sold in the markets as Coleworts, which, if they are of the Sugar-loaf kind, is one of the sweetest greens from December to April yet known. Indeed, where farmers sow Coleworts to feed their milch-cattle in the spring, when there is a scarcity of herbage, the common Colewort is to be preferred, as being so very hardy that no frost will destroy it. The best method to cultivate this plant in the fields is, to sow the seeds about the beginning of July, choosing a moist season, which will bring up the plants in about ten days or a fortnight; the quantity of seed for an acre of land is nine pounds: when the plants have got five or six leaves, they should be hoed, as is practised for Turneps, cutting down all the weeds from amongst the plants, and also thinning the plants where they are too thick; but they should be kept thicker than Turneps, because they are more in danger of being destroyed by the fly: this work should be performed in dry weather, that the weeds may be killed; for if it should prove moist soon after, the weeds will take root again, and render the work of little use. About six weeks after, the plants should have a second hoeing, which, if carefully performed in dry weather, will entirely destroy the weeds, and make the ground clean, so that they will require no farther culture. In the spring they may either be drawn up and carried out to feed the cattle, or they may be turned in to feed upon them as they stand; but the former method is to be preferred, because there will be little waste; whereas, when the cattle are turned in amongst the plants, they will tread down and destroy more than they eat, especially if they are not fenced off by hurdles.

The perennial Colewort is also little cultivated in the gardens near London at present. This is very hardy, and may be cultivated in the same manner as the former sort. This will continue two years before it runs up to seed, and will afterwards produce many side shoots, and in poor land will continue three or four years; but in rich soils it will not last so long. This may be used as the former sort, to feed cattle; for it is not so good for the table (unless in very severe frost) as the plants which are now cultivated for that purpose.

The fifth sort came from China, where it is cultivated as an esculent plant; of this there are two or three varieties which I have cultivated some years, but I find them as variable as our common Cabbage. These are annual plants, which, if sown in April, will flower in July, and perfect their seeds in October. They never close their leaves to form a head, like the common Cabbage, but grow open and loose, more like the wild Navew, and are very unfit for the table. As these are generally in their perfection for use the beginning of July, I imagined their strong flavour and toughness might be occasioned by the warmth of the season; therefore I sowed some of the seeds in July, that I might make trial of them in winter; but in the midst of frost, I found them much worse than our common Colewort, so I thought them not worth propagating.

The other two sorts of Cabbage are varieties fit for a botanic garden, but are plants of no use. These may be propagated by sowing their seeds on a bed of light earth, early in the spring, in the place where they are designed to remain (for they do not bear transplanting well.) When the plants are come up pretty strong, they should be thinned, so as to leave them four or five inches apart; and they must be constantly kept clear from weeds. In June they will flower; and their seeds will ripen the beginning of August, which, if permitted to fall, the plants will come up, and maintain themselves without any farther care but to keep them clear from weeds. They are annual plants, and perish when they have perfected their seeds.

The best method to save the seeds of all the best sorts of Cabbages is, about the end of November you should make choice of some of your best Cabbages, which you should pull up, and carry to some shed, or other covered place, where you should hang them up for three or four days by their stalks, that the water may drain from between their leaves; then plant them in some border, under a hedge or pale, quite down to the middle of the Cabbage, leaving only the upper part of the Cabbage above ground, observing to raise the earth about it, so that it may stand a little above the level of the ground; especially if the ground is wet, they will require to be raised pretty much above the surface.

If the winter should prove very hard, you must lay a little straw or Pease-haulm lightly upon them, to secure them from the frost, taking it off as often as the weather proves mild, lest by keeping them too close they should rot. In the spring of the year these Cabbages will shoot out strongly, and divide into a great number of small branches: you must therefore support their stems, to prevent their being broken off by the wind; and if the weather should be very hot and dry when they are in flower, you should refresh them with water once a week all over the branches, which will greatly promote their feeding, and preserve them from mildew.

When the pods begin to change brown, you will do well to cut off the extreme part of every shoot with the pods, which will strengthen your seeds; for it is generally observed, that those seeds which grow near the top of the shoots, are very subject to run to seed before they cabbage; so that by this there will be no loss, but a great advantage, especially if you have more regard to the quality than to the quantity of the seeds, which indeed is not always the case, when it is intended for sale; but those who save it for their own use, should be very careful to have it good.

When your seeds begin to ripen, you must be particularly careful, that the birds do not destroy it; for they are very fond of these seeds. In order to prevent their mischief, some use old nets, which they throw over their seeds, to prevent their getting to it: but this will not always do, for, unless the nets are very strong, they will force their way thro' them, as I have often seen; but the best method I know, is to get a quantity of birdlime, and dawb over a parcel of slender twigs, which should be fastened at each end to

stronger sticks, and placed near the upper part of the seed, in different places, so that the birds may alight upon them, by which means they will be fastened thereto, where you must let them remain a considerable time, if they cannot get off themselves: and although there should be but few birds caught, yet it will sufficiently terrify the rest, that they will not come to that place again for a considerable time after (as I have experienced.)

When your seed is fully ripe, you must cut it off, and, after drying, thresh it out, and preserve it in bags for use.

But in planting Cabbages for seed, I would advise never to plant more than one sort in a place, or near one another: as for example, never plant red and white Cabbages near each other, nor Savoy with either white or red Cabbages; for I am very certain they will, by the commixture of the effluvia, produce a mixture of kinds; and it is wholly owing to this neglect, that the gardeners rarely save any good red Cabbage-seed in England, but are obliged to procure fresh seeds from abroad, as supposing the soil or climate of England alters them from red to white, and of a mixed kind between both; whereas, if they would plant red Cabbages by themselves for seeds, and not suffer any other to be near them, they might continue the kind as good in England, as in any other part of the world; for in the Dutch gardens, from whence the best seeds of red Cabbages are procured, they cultivate no other sort.

Cauliflowers have of late years been so far improved in England, as to exceed in goodness and magnitude what are produced in most parts of Europe; and by the skill of the gardener, are continued for several months together; but the most common season for the great crop, is in May, June, and July. I shall therefore begin with directions for obtaining them in this season.

Having procured a parcel of good seed, of an early kind, you must sow it about the twenty-first of August, upon an old Cucumber or Melon-bed, sifting a little earth over the seeds, about a quarter of an inch thick; and if the weather should prove extreme hot and dry, you should shade the bed with mats, to prevent the earth from drying too fast, which would endanger the spoiling your seed; and give it gentle waterings, as you may see occasion. In about a week's time your plants will appear above ground, when you must take off your coverings by degrees, but do not expose them too much to the open sun at first. In about a month's time after sowing, your plants will be fit to prick out, you should therefore put some fresh earth upon your old Cucumber or Melon-beds; or where these are not to be had, some beds should be made with a little new dung, which should be trodden down close, to prevent the worms from getting thro' it; but it should not be hot dung, which would be hurtful to the plants at this season, especially if it proves hot; into this bed you should prick your young plants, at about two inches square, observing to shade and water them at first planting; but do not water them too much after they are growing, nor suffer them to receive too much rain, if the season should prove wet, which would be apt to make them black shanked (as the gardeners term it, which is no less than a rottenness in their stems,) and is the destruction of the plants so affected.

In this bed they should continue till about the thirtieth of October, when they must be removed into the place where they are to remain during the winter season, which, for the first sowing, is commonly under bell or hand-glasses, to have early Cauliflowers, and these should be of an early kind: but in order to have a succession during the season, you should be provided with another more late kind, which should be sown four or five days after the other, and managed as was directed for them.

In order to have very early Cauliflowers, you should make choice of a good rich spot of ground, that is well defended from the north, east, and west winds, with

with hedges, pales, or walls; but the first is to be preferred, if made with reeds, because the winds will fall dead in these, and not reverberate as by pales or walls. This ground should be well trenched, burying therein a good quantity of rotten dung; then level your ground; and if it be naturally a wet soil, you should raise it up in beds about two feet and a half, or three feet broad, and four inches above the level of the ground; but if your ground is moderately dry, you need not raise it at all: then plant your plants, allowing about two feet six inches distance from glass to glass, in the rows, always putting two good plants under each glass, which may be at about four inches from each other; and if you design them for a full crop, they may be three feet and a half, row from row: but if you intend to make ridges for Cucumbers or Melons between the rows of Cauliflower plants (as is generally practised by the gardeners near London,) you must then make your rows eight feet asunder.

When you have planted your plants, if the ground is very dry, you should give them a little water, and then set your glasses over them, which may remain close down upon them, until they have taken root, which will be in about a week or ten days time, unless there should be a kindly shower of rain; in which case you may set off the glasses, that the plants may receive the benefit of it; and in about ten days after planting, you should be provided with a parcel of forked sticks or bricks, with which you should raise your glasses about three or four inches on the side toward the south, that your plants may have free air. In this manner your glasses should remain over the plants night and day, unless in frosty weather, when you should set them down as close as possible: or if the weather should prove very warm, which many times happens in November, and sometimes in December; in this case, you should keep your glasses off in the day-time, and put them on only in the night, lest, by keeping the glasses over them too much, you should draw them into flower at that season, which is many times the case in mild winters, especially if unskillfully managed.

Toward the latter end of February, if the weather proves mild, you should prepare another good spot of ground, to remove some of the plants into from under the glasses, which should be well dunged and trenched (as before;) then set off the glasses, and, after making choice of one of the most promising plants under each glass, which should remain for good, take away the other plant, by raising it up with a trowel, &c. so as to preserve as much earth to the root as possible; but have a great regard to the plant that is to remain, not to disturb or prejudice its roots: then plant your plants which you have taken out, at the distance before directed, viz. if for a full crop, three feet and a half, row from row; but if for ridges of Cucumbers between them, eight feet, and two feet four inches distance in the rows: then, with a small hoe, draw the earth up to the stems of the plants which were left under the glasses, taking great care not to let the earth fall into their hearts; and set your glasses over them again, raising your props an inch or two higher than before, to give them more air, observing to take them off whenever there may be some gentle showers, which will greatly refresh the plants.

In a little time after, if you find your plants grow so fast as to fill the glasses with their leaves, you should then slightly dig about the plants, and raise the ground about them in a bed broad enough for the glasses to stand about four inches high, which will give your plants a great deal of room by raising the glasses so much higher, when they are set over them; and by this means they may be kept covered until April, which otherwise they could not, without prejudice to the leaves of the plants: and this is a great advantage to them; for many times we have returns of severe frosts at the latter end of March, which prove very hurtful to these plants, if exposed

thereto, especially after having been nursed up under glasses.

After you have finished your beds, you may set your glasses over your plants again, observing to raise your props pretty high, especially if the weather be mild, that they may have free air to strengthen them; and in mild soft weather set off your glasses, as also in gentle showers of rain; and now you must begin to harden them by degrees to endure the open air: however, it is advisable to let your glasses remain over them as long as possible, if the nights should be frosty, which will greatly forward your plants; but be sure do not let your glasses remain upon them in very hot sun-shine, especially if their leaves press against the sides of the glasses; for I have often observed, in such cases, that the moisture which hath risen from the ground, together with the perspiration of the plants, which, by the glasses remaining over them, hath been detained upon the leaves of the plants, and when the sun hath shone hot upon the sides of the glasses, hath acquired such a powerful heat from the beams thereof, as to scald all their larger leaves, to the no small prejudice of the plants: nay, sometimes I have seen large quantities of plants so affected therewith, as never to be worth any thing after.

If your plants have succeeded well, toward the end of April some of them will begin to fruit; you must therefore look over them carefully every other day, and when you see the flower plainly appear, you must break down some of the inner leaves over it to guard it from the sun, which would make the flower yellow and unsightly, if exposed thereto; and when you find your flower at its full bigness (which you may know by its outside, parting, as if it would run,) you must then draw it out of the ground, and not cut them off, leaving the stalk in the ground, as is by some practised; and if they are designed for present use, you may cut them out of their leaves; but if designed to keep, you should preserve their leaves about them, and put them into a cool place: the best time for pulling of them is in a morning, before the sun hath exhaled the moisture; for Cauliflowers, pulled in the heat of the day, lose that firmness which they naturally have, and become tough.

But to return to our second crop (the plants being raised and managed as was directed for the early crop, until the end of October;) you must then prepare some beds, either to be covered with glass-frames, or arched over with hoops, to be covered with mats, &c. These beds should have some dung laid at the bottom, about six inches or a foot thick, according to the size of your plants; for if they are small, the bed should be thicker of dung, to bring them forward, and so *vice versa*: this dung should be beat down close with a fork, in order to prevent the worms from finding their way through it; then lay some good fresh earth about four or five inches thick thereon, in which you should plant your plants about two inches and a half square, observing to shade and water them until they have taken fresh root: but be sure do not keep your coverings close, for the warmth of the dung will occasion a large damp in the bed, which, if pent in, will greatly injure the plants.

When your plants have taken root, you must give them as much free open air as possible, by keeping the glasses off in the day-time as much as the weather will permit; and in the night, or at such times as the glasses require to be kept on, raise them up with bricks or other props to let in fresh air, unless in frosty weather; at which time the glasses should be covered with mats, straw, and Pease-haulm, &c. but this is not to be done except in very hard frosts: you must also observe to guard them against great rain, which in winter time is very hurtful to them; but in mild weather, if the glasses are kept on, they should be propped to admit fresh air; and if the under leaves grow yellow and decay, be sure to pick them off; for if the weather should prove very bad in winter, so that you should be obliged to keep them close covered for two or three days together, as it sometimes happens,

B R A

happens, these decayed leaves will render the inclosed air very noxious; and the plants perspiring pretty much at that time, are often destroyed in vast quantities.

In the beginning of February, if the weather proves mild, you must begin to harden your plants by degrees, that they may be prepared for transplantation; and the ground where you intend to plant your Cauliflowers out for good (which should be quite open from trees, &c. and rather moist than dry,) having been well dunged and dug, should be sown with Radishes a week or fortnight before you intend to plant out your Cauliflowers: the reason why I mention the sowing of Radishes particularly, is this, viz. that if there are not some Radishes amongst them, and the month of May should prove hot and dry, as it sometimes happens, the fly will seize your Cauliflowers, and eat their leaves full of holes, to their prejudice, and sometimes their destruction; whereas, if there are Radishes upon the spot, the flies will take to them, and never meddle with the Cauliflowers so long as they last. Indeed, the gardeners near London mix Spinach with their Radish-feed, and so have a double crop, which is an advantage where ground is dear, or where persons are straitened for room; otherwise it is very well to have only one crop amongst the Cauliflowers, that the ground may be cleared in time.

Your ground being ready, and the season good, about the middle or end of February, you may begin to plant out your Cauliflowers: the distance which is generally allowed by the gardeners near London (who plant other crops between their Cauliflowers to succeed them, as Cucumbers for pickling, and winter Cabbages) is every other row four feet and a half apart, and the intermediate rows two feet and a half, and two feet two inches distance in the rows; so that in the latter end of May, or beginning of June (when the Radishes and Spinach are cleared off,) they put in seeds of Cucumbers for pickling, in the middle of the wide rows, at three feet and a half apart; and in the narrow rows, plant Cabbages for winter use, at two feet two inches distance, so that these stand each of them exactly in the middle of the square between four Cauliflower-plants; and these, after the Cauliflowers are gone off, will have full room to grow, and the crop be hereby continued in a succession thro' the whole season.

About three weeks or a month after your Cauliflowers are planted out, the Radishes between them will be fit to hoe; at which time, when you are hoeing out the Radishes where they are too thick, you should cut off all such as grow immediately about the Cauliflowers, and would prove hurtful to them, by drawing them up tall and weak; and also at that time draw the earth up to the stems of the plants, being careful not to let any get into their hearts (as was before directed;) and when your Radishes are fit to pull, be sure to clear round the Cauliflowers first, and keep drawing the earth up to their stems as they advance in height, which will keep their stems from being hardened by the weather, and be of singular service to your plants.

There are many people who are very fond of watering Cauliflower-plants in summer, but the gardeners near London have almost wholly laid aside this practice, as finding a deal of trouble and charge to little purpose; for if the ground be so very dry as not to produce tolerable good Cauliflowers without water, it seldom happens, that watering them renders them much better; and when once they have been watered, if it is not constantly continued, it had been much better for them if they never had any; as also if it be given them in the middle of the day, it rather helps to scald them: so that, upon the whole, if care be taken to keep the earth drawn up to their stems, and clear them from every thing that grows near them, that they may have free open air, you will find that they will succeed better without than with water, where any of these cautions are not strictly observed.

When your Cauliflowers begin to fruit, you must

B R E

often look over them, to turn down their leaves; as was before directed, to preserve their whiteness; and when they are full grown, observe the former directions in pulling them, &c. but wherever you meet with an extraordinary good Cauliflower, whose curd is hard and white, and perfectly free from any frothiness about the edges, you should suffer it to remain for seed, keeping the leaves close down upon it until the flower hath shot out stems, and then remove the leaves from them by degrees, but do not expose them too much to the open air at first. As the stems advance, you must take the leaves quite away; and when they begin to branch out, you should fix three pretty strong stakes, at equal angles, about it, surrounding them with packthread, &c. to support their branches, which would be otherwise liable to break with the wind.

When your pods begin first to be formed, if the weather proves dry, you should give them a little water all over (with a watering-pot that hath a rose to it;) which will promote the progress of the seeds, and preserve them from mildew, which is often hurtful to the seeds; and, when your seeds are ripe, you must cut it off, and hang it up to dry, and rub it out as was directed for Cabbage-feed: and although your flowers do not produce so much seed as those which were of a softer or frothy nature, yet the goodness of such seeds will sufficiently recompense for the quantity; and any person who was to purchase his seeds, had better give ten shillings an ounce for such seed than two for the seeds commonly saved for sale, as the gardeners about London have experienced, who will never buy any seeds of this kind, if they do not know how they were saved.

But in order to have a third crop of Cauliflowers, you should make a slender hot-bed in February, in which you should sow the seeds, covering them a quarter of an inch thick with light mould, and covering the bed with glass-frames: you should now and then gently refresh the bed with water, observing to raise the glasses with bricks or props in the day-time, to let in fresh air; and when the plants are come up, and have gotten four or five leaves, you should prepare another hot-bed to prick them into, which may be about two inches square; and in the beginning of April harden them by degrees, to fit them for transplanting, which should be done the middle of that month, at the distance directed for the second crop, and must be managed accordingly: these (if the soil is moist where they are planted, or the season cool and moist) will produce good Cauliflowers about a month after the second crop is gone, whereby their season will be greatly prolonged.

There is also a fourth crop of Cauliflowers, which is raised by sowing the seed about the 23d of May; and being transplanted, as hath been before directed, will produce good Cauliflowers in a kindly season and good soil, after Michaelmas, and continue thro' October and November; and, if the season permit, often a great part of December.

The reason why I fix particular days for the sowing of this seed, is because two or three days often make a great difference in their plants; and because these are the days usually fixed by the gardeners near London, who have found their crops to succeed best when sown at those times, although one day, more or less, will make no great odds. I have also, in this edition, altered the days to the new style.

BREYNIA. See CAPPARIS.

BROMELIA. Plum. Nov. Gen. 46. tab. 8. Lin. Gen. Plant. 356.

The CHARACTERS are,

It hath a three-cornered permanent empalement cut into three parts, upon which the germen is situated. The flower hath three long narrow petals, which are erect, each having a nectarium joined to it above the base. It hath six stamina the length of the petals, which are terminated by oblong summits. The germen is situated below the receptacle, supporting a slender style, crowned by a trifid obtuse stigma. The empalement afterward becomes

an oblong capsule, divided by a partition in the middle, to which the seeds are fixed quite round; these are smooth and almost cylindrical.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style. Dr. Dillenius has supposed this to be the same with Plumier's Karatas, which mistake he was led into by Plumier's drawing, where the flower of his Caraguata is joined to the fruit of his Karatas, and *vice versa*; and from hence Dr. Linnæus has been induced to join these and the Ananas together, making them only species of the same genus.

The SPECIES are,

1. BROMELIA (*Nudicaulis*) foliis radicalibus dentato-spinosis caulinis integerrimis. Lin. Sp. Plant. 286. *Bromelia with lower leaves indented and prickly, and those of the stalks entire.* Bromelia pyramidata, aculeis nigris. Plum. Nov. Gen. 46.
2. BROMELIA (*Lingulata*) foliis ferrato-spinosis obtusis, spicis alternis. Lin. Sp. Plant. 285. *Bromelia with sawed, prickly, obtuse leaves, and spikes of flowers growing alternate.* Bromelia ramosa & racemosa foliis Arundinaceis ferratis. Plum. Nov. Gen. 46.

The first sort hath leaves very like some of the sorts of Aloes, but not so thick and succulent, which are sharply indented on their edges, where they are armed with strong black spines; from the center of the plant arises the flower-stalk, which is near three feet high, the lower part of which is garnished with entire leaves, placed alternately at every joint. The upper part of the stalk is garnished with flowers, set in a loose spike or thyse; these have three narrow herbaceous petals sitting upon the germen, and six slender stamina, with the style, which are shorter than the petals. These flowers in the country where they naturally grow, are succeeded by oval seed-vessels, having a longitudinal partition, in the center of which are fastened cylindrical seeds on every side, which are smooth.

The second sort hath shorter leaves than the first, which stand erect, and are narrow at the base, increasing in width gradually to the top, where they are broadest; these are sharply sawed on their edges, and are of a deep green colour. The flower-stem arises from the center of the plant, which divides upward into several branches; the upper part of these are garnished with spikes of flowers, which come out alternately from the sides of the branches, each having a narrow entire leaf just below it, which is longer than the spike. The flowers are placed very close on the spikes, each having three short petals situated upon the globular empalement; when these decay, the empalement turns to an oval pointed seed-vessel, inclosing seeds of the same shape with the former.

Both these plants grow naturally in very warm countries. Father Plumier, who gave this title to the genus, found them growing in the French Islands in America; and the late Dr. Houstoun observed them growing in Jamaica, and in several parts of the Spanish West-Indies. The first sort also grows on the coast of Guinea, from whence I received the seeds; and the second sort was sent me from St. Christopher's.

These plants are propagated by seeds, which must be procured from the country where they grow naturally, for they do not produce any in England. These must be sown in small pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark; the earth in these pots should be sprinkled over with water two or three times a week, according to the heat of the weather, but must not have too much moisture. If the seeds are good, the plants will appear in about five or six weeks, and in a month after will be fit to transplant, when they should be carefully shaken out of the pots, and each planted in a separate small pot filled with the same earth as before; then they must be plunged again into a moderate hot-bed, observing frequently to sprinkle them over with water, but be cautious of giving them too much, lest the roots should be thereby rotted.

During the summer season the plants should have a moderate share of air, in proportion to the heat of the weather; and, in autumn, they must be removed in the bark-stove, and treated in the same manner as the Ananas, or Pine Apple, with which management they will make good progress; but after the first winter, they may be placed upon stands in the dry stove, though they will thrive much better if they are constantly kept in the tan-bed, and treated like the Ananas, and will flower in three or four years; whereas those in the dry stove will not flower in twice that time.

The other parts of their culture is only to shift them into fresh earth when they require it; but they should by no means be put into large pots, for they will not thrive if they are over-potted; nor must they have much wet, especially in winter.

These plants make a pretty variety in the hot-house, so those who have room, may allow a plant or two of each sort to have a place in their collection of exotic plants.

BROOM, the common. See SPARTIUM.

BROOM, the Spanish. See SPARTIUM and GENISTA.

BROWALLIA. Lin. Gen. Plant. 691. Hort. Cliff. 318.

The CHARACTERS are,

The empalement is tubulous, of one leaf, and indented at the top in five unequal parts. The flower is funnel-shaped, of one leaf, having a cylindrical tube twice the length of the empalement; the upper part is spread open, and divided into five parts, the upper segment or lip being a little larger than the others, which are equal. It hath four stamina included in the chaps of the petal, the two upper being very short, and the two under broad, longer, and reflexed to the mouth of the tube, which inclose them; these are terminated by single incurved summits. In the center is situated an oval germen, supporting a slender style the length of the tube, crowned by a thick, compressed, indented stigma. The empalement afterward becomes an oval obtuse vessel with one cell, opening at the top in four parts, and filled with small compressed seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamina, and the seeds included in a capsule.

The SPECIES are,

1. BROWALLIA (*Demissa*) pedunculis unifloris. Hort. Cliff. 318. *Browallia with one flower on a foot-stalk.* The title of Browallia was given to it by Dr. Linnæus, in honour of professor Browall, of Amsterdam.
2. BROWALLIA (*Elata*) pedunculis unifloris multiflorisque. Lin. Sp. 880. *Browallia with one flower on each foot-stalk, and sometimes many.*

The seeds of the first sort were sent me by Mr. Robert Millar, from Panama, in the year 1735; which succeeded in the Chelsea garden, where it has continued to flower, and produce seeds every year, but the plants are annual, so perish in autumn: the seeds of this plant must be sown upon a hot-bed in the spring, and the plants brought forward on another, otherwise they will not perfect their seeds in England. Some of these plants may be transplanted in June into the borders of the flower-garden, where, if the season proves warm, they will flower and perfect seeds; but lest these should fail, there should be two or three plants kept in the stove for that purpose. The plants usually grow about two feet high, and spread out into lateral branches, garnished with oval leaves which are entire, ending in a point, having short foot-stalks. Toward the end of the branches the flowers are produced singly, upon pretty long foot-stalks, arising from the wings of the leaf. These have a short empalement of one leaf, which is cut into five parts; out of the center of the empalement the flower arises, which is crooked and bent downward; the top of the tube is spread open, and the brim, or open part of the flower, has some resemblance to a lipped flower, being irregular. It is of a bright

bright blue colour, sometimes inclining to a purple or red, and often there are flowers of three colours on the same plant. When these fall away, the germen in the center becomes an oval capsule of one cell, filled with small, brown, angular seeds. It flowers in July, August, and September, and the seeds are ripe in five or six weeks after.

When this plant was first raised in the Chelsea garden, I gave it the title of Dalea, in honour to Mr. Dale, an eminent botanist, and a great friend of Mr. Ray's. By this title it was delivered to the Royal Society, and printed in the Philosophical Transactions, and also in the catalogue of the Chelsea garden: and by the same I communicated the seeds to Doctor Linnæus, who afterward changed the name to Browallia, and printed it in the catalogue of Mr. Clifford's garden; where there is a figure of it exhibited, so that this latter title is become almost universal among botanists.

The second sort grows naturally in Peru, from whence the younger Jussieu sent the seeds; this plant rises about the same height as the first, but hath stronger stalks, and sends out a greater number of branches, so is much more bushy than that; the flowers are produced upon foot-stalks, which proceed from the wings of the leaves; some of these foot-stalks sustain one, others three, or more flowers, of a dark blue colour; these are succeeded by oval capsules, filled with small angular seeds.

This plant is annual, and requires the same culture as the first sort, with which it will produce plenty of seeds.

BRUNELLA, Self-heal. See **PRUNELLA**.

BRUNSFELSIA. Plum. Nov. Gen. 12. Lin. Gen. Plant. 230. This plant takes its name from Dr. Brunsfelsius, a famous physician.

The CHARACTERS are,

The empalement is permanent, bell-shaped, and of one leaf, which is cut into five blunt segments at the top. The flower is of one leaf, and funnel-shaped, having a long tube, but spreads open at the top, where it is divided into five obtuse segments; it hath five stamina the length of the tube, which are inserted in the petal, and are terminated by oblong summits. In the center is placed a small round germen, supporting a slender style the length of the tube, which is crowned by a thick stigma. The empalement afterward becomes a globular berry with one cell, inclosing a great number of small seeds, which adhere to the skin of the fruit.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and but one style.

We know but one SPECIES of this genus, viz.

BRUNSFELSIA. (*Americana*.) Lin. Sp. Plant. 191. *American Brunsfelsia*. Brunsfelsia flore albo, fructu croceo molli. Plum. Nov. Gen. 12.

This plant rises with a woody stem to the height of eight or ten feet, sending out many side branches, which are covered with a rough bark, garnished with oblong leaves which are entire, and on the lower part of the branches come out single; but toward their extremity, they are placed on every side, and are unequal in size. At the extremity of the branches, the flowers are produced, generally three or four together. These are almost as large as those of the greater Bindweed, but have very long, narrow, hairy tubes; the brim is expanded in the form of the Convolvulus, but is deeply divided into five obtuse segments, which are indented on their border. After the flower is past, the empalement turns to a round soft fruit, inclosing many oval seeds, which are situated close to the cover or skin, to which they adhere.

This plant grows naturally in most of the sugar islands in America, in which places they call it Trumpet Flower; but in the English gardens, it is at present very rare. It may be propagated from seeds, which should be sown early in the spring in pots filled with light earth, and plunged into a hot-bed of tanners

bark, observing to water the earth as often as you find it necessary. When the plants are come up, they should be transplanted each into a separate small pot filled with fresh light earth, and plunged into the hot-bed again; observing to water and shade the plants until they have taken root; after which they must have air admitted to them every day, in proportion to the warmth of the season. When the plants have advanced so high as not to be contained in the frames, they should be removed into the bark-stove, where, during the summer months, they should have a large share of free air, but in winter they must be kept very close. With this management the plants will be very strong, and produce their flowers every season. These plants may also be increased by planting cuttings in the spring, before they begin to make new shoots, in pots filled with fresh light earth, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root; after which, they must be managed as hath been directed for other tender exotic plants from the same countries.

BRUSCUS. See **RUSCUS**.

BRYONIA [this plant is so called from *Brion*, moss; or hair, because it bears a flower which is soft and hairy.] *Briony*.

The CHARACTERS are,

It hath male and female flowers on the same plant. The male flowers have an empalement of one leaf, which is bell-shaped, and indented in five parts at the top. The flower is bell-shaped, adhering to the empalement, and cut into five segments. It hath three short stamina and five summits, two of the stamina having double summits, and the other one. The female flowers sit upon the germen, and have a deciduous empalement, but the petal is the same with those of the male. The germen which is under the flower, supports a trifid spreading style, crowned by a spreading indented stigma. The germen afterward becomes a smooth globular berry, containing oval seeds adhering to the skin.

This genus of plants is ranged in the tenth section of Linnæus's twenty-first class, intitled Monœcia Syngenesia, from its having male and female flowers on the same plant, and the stamina joined with the style.

The SPECIES are,

1. **BRYONIA** (*Alba*) foliis palmatis utrinque calloso-scarbris. Hort. Cliff. 453. *Briony with palmated leaves, which are rough and callous on both sides*. *Bryonia aspera*, five alba baccis rubris. C. B. P. 297. *White Briony with red berries*.
2. **BRYONIA** (*Africana*) foliis palmatis quinquepartitis utrinque lævibus, laciniis pinnatifidis. Lin. Sp. 1438. *Briony with palmated leaves cut into five segments, which are smooth on each side*. *Bryonia Africana laciniata*, tuberosa radice, floribus herbaceis. Par. Bat. 107.
3. **BRYONIA** (*Cretica*) foliis palmatis supra calloso-punctatis. Hort. Cliff. 453. *Cretan Briony with palmated leaves, whose upper surface is studded with callous spots*. *Bryonica Cretica maculata*. C. B. P. 297.
4. **BRYONIA** (*Racemosa*) foliis trilobis supra calloso-punctatis, fructu racemoso ovali. *Briony with trilobate leaves, whose upper sides are marked with callous spots, and oval fruit growing in bunches*. *Bryonia olivæ fructu rubro*. Plum. Cat. 3.
5. **BRYONIA** (*Variegata*) foliis palmatis, laciniis lanceolatis, supra punctatis inferne lævibus, fructu ovato sparso. *Briony with palmated leaves, whose segments are spear-shaped, and their upper side spotted, but their under smooth, and an oval scattered fruit*. *Bryonia Americana fructu variegato*. Dillen.
6. **BRYONIA** (*Bonariensis*) foliis palmatis quinquepartitis hirsutis, laciniis obtusis. *Briony with hairy palmated leaves divided into five parts, and obtuse segments*. *Bryonia Bonariensis fici folio*. Hort. Elth. 58.

The first sort grows upon dry banks, under hedges, in many parts of England; but may be cultivated in a garden for use, by sowing the berries, in the spring of the year, in a dry poor soil; where they will in two years time, grow to be large roots, provided they are not too close. The roots of this plant have been

been formerly, by impostors, brought into an human shape, and carried about the country, and shewn for Mandrakes to the common people, who were easily imposed on by their credulity, and these got good livings thereby. The method which these people practised, was to find a young thriving Briony plant, then they opened the earth all round the plant, being careful not to disturb the lower fibres; and (being prepared with such a mould, as is used by the people who make plaster figures) they fixed the mould close to the root, fastening it with wire, to keep it in its proper situation; then they filled the earth about the root, leaving it to grow to the shape of the mould, which is effected in one summer; so that if this be done in March, by September it will have the shape. The leaves of this plant are also often imposed on the people in the market for Mandrake leaves, although there is no resemblance between them, nor any agreement in quality.

The second and fourth sorts are perennial plants, their roots remaining several years, but their branches decay every winter. These roots must be planted in pots filled with fresh light earth, and in winter must be placed in the green-house, to protect them from frost and great rains; which would destroy them, if they were exposed thereto. During the winter season, they should have very little water given them; but in summer, when they are exposed to the open air, they must be frequently refreshed with water in dry weather. They flower in July, and in warm summers will perfect their seeds.

The third, fifth, and sixth sorts, are annual plants; these must be raised on a hot-bed early in the spring, and when the plants are about three inches high, they should be each transplanted into a small pot filled with fresh light earth, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root. When the plants are grown so large, as to ramble about on the surface of the bed, and begin to entangle with other plants, they should be shifted into larger pots, and placed in the bark-stove, where their branches may be trained to the wall, or against an espalier, that they may have sun and air, which is absolutely necessary for their producing fruit. When these plants are full of fruit, they make a pretty variety in the stove amongst other exotic plants.

The second and fourth sorts are also propagated from seeds, which should be sown on a hot-bed; and when the plants are fit to transplant, they should be put into pots; and after they have taken root, should be inured to bear the open air by degrees; where they may remain during the summer season, but in winter they must be sheltered under a hot-bed frame. The fourth sort is much tenderer than the former.

BRYONIA NIGRA. See TAMNUS.

BUBON. Lin. Gen. Plant. 312. Apium. C. B. 154. Ferula. Herm. Par. 163. Macedonian Parsley.

The CHARACTERS are,

It hath an umbelliferous flower, the greater, or general umbel, is composed of about ten smaller, those which are situated in the middle being the shortest; the small umbels have near twenty rays. The general involucre hath five pointed spear-shaped leaves, which spread open and are permanent; those of the smaller umbels, consist of many little leaves of the same length with the umbel: the empalement of the flower is permanent, small, and indented in five parts; the flower is composed of five spear-shaped petals, which turn inward; it hath five stamina the length of the petals, terminated by single summits. The oval germen is situated below the flower, supporting two bristly styles which are permanent, and the length of the stamina, crowned by obtuse stigma. The germen afterward becomes an oval, channelled, hairy fruit, dividing in two parts, each having an oval seed, plain on one side, but convex on the other.

This genus of plants is ranged in the second section of Linnaeus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **BUBON** (*Macedonicum*) foliolis rhombeo-ovatis crenatis, umbellis numerosissimis. Hort. Cliff. 95. *Bubon with oval, rhomboid, crenated leaves, and many umbels.* Apium Macedonicum. C. B. P. 154. *Macedonian Parsley.*
2. **BUBON** (*Rigidius*) foliolis linearibus. Hort. Cliff. 95. *Bubon with very narrow leaves.* Ferula durior five rigidis & brevissimis foliis. Boccon. Mus. 2. 84.
3. **BUBON** (*Galbanum*) foliolis rhombeis dentatis glabris striatis umbellis paucis. Hort. Cliff. 96. *Bubon with smooth rhomboid leaves and few umbels.* Ferula Africana galbanifera folio & facie ligustici. Par. Bat. 163.
4. **BUBON** (*Gumiferum*) foliolis glabris inferioribus rhombeis serratis, superioribus pinnatifidis tridentatis. Prod. Leyd. 100. *Bubon with smooth rhomboid under leaves which are sawed, and upper leaves winged and indented in three parts.* Ferula Africana galbanifera folio myrrhidis. Hort. Amst. p. 115.

The first sends out many leaves from the root, the lower growing almost horizontally, spreading near the surface of the ground: the foot-stalk of each leaf divides into several other smaller, garnished with smooth rhomb-shaped leaves, which are of a bright, pale, green colour, indented on their edges. In the center of the plant arises the flower-stem, which is little more than a foot high, dividing into many branches, each being terminated by an umbel of white flowers, which are succeeded by oblong hairy seeds. It flowers in July, and the seeds ripen in autumn, soon after which the plant decays.

This plant in warm countries is biennial; the plants which rise from seeds one year, produce flowers and seeds the next, and then perish: but in England, they seldom flower till the third or fourth year from seed; but whenever the plant flowers, it always dies.

It is propagated by seeds, which should be sown on a bed of light sandy earth, either early in the autumn, or in April; and if the season prove warm and dry, the ground should be shaded in the heat of the day, and frequently refreshed with water, which is a sure method to bring up the plants; for where this is not practised, the seeds often fail, or remain long in the ground. When the plants come up, they will require no other care but to be kept clean from weeds, till the beginning of October, when they should be carefully taken up, and planted in a warm border of dry ground; and a few of them should be put into pots, that they may be sheltered under a frame in winter; for in severe frost, those which are exposed to the open air, are frequently killed; though, in moderate winters, they will live abroad without covering; but it is a secure way to preserve the species, to keep two or three plants in pots, in shelter, during the winter, lest those abroad should be destroyed. The seeds of this plant is one of the ingredients in Venice treacle.

The second sort grows naturally in Sicily, from whence I received the seeds. This is a low perennial plant, having short stiff leaves, which are very narrow: the flower-stalk rises near a foot high, which is terminated by an umbel of small white flowers, which are succeeded by small, oblong, channelled seeds. It flowers in June, and the seeds ripen in September. It is propagated by seeds, and should have a dry soil and a warm situation, where the plants will continue several years. It is a plant of little beauty or use, so is only preserved for the sake of variety.

The third sort rises with an upright stalk to the height of eight or ten feet, which at bottom is ligneous, having a purplish bark, covered with a whitish powder, which comes off when handled; the upper part of the stalk is garnished with leaves at every joint, the foot-stalks half embracing them at their base; branching out into several smaller, like those of the common Parsley, and are set with leaves like those of Lovage, but smaller, of a grey colour; the top of the stalk is terminated by an umbel of yellow flowers,

flowers, which are succeeded by oblong channelled seeds, having a thin membrane or wing on their border. It flowers in August, but hath not produced seeds in England. When any part of the plant is broken, there issues out a little thin milk of a cream colour, which hath a strong scent of Galbanum.

The fourth sort rises with a ligneous stalk about two feet high, garnished with leaves at each joint, which branch out like the former; but the small leaves or lobes are narrow and indented, like those of Bastard Hemlock. The stalk is terminated by a large umbel of small white flowers, which are succeeded by seeds like those of the former sort.

These plants are both natives of Africa. They are propagated by seeds, which should be sown in pots filled with light loamy earth, as soon as they arrive; which, if it happens toward autumn, should be plunged into a bed of tanners bark, where the heat is gone, and screened from frost in winter. In the spring the plants will come up, and by the middle of April will be fit to remove, when they should be carefully shaken out of the pots, being careful not to tear off their roots, and plant them each into a separate small pot, filled with the same earth as before; then plunge the pots into the tan again, and water them to settle the earth to the roots of the plants, and shade them from the sun in the day time, until they have taken new root; after this they must be inured gradually to bear the open air; into which they should be removed in June, and placed with other exotic plants in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy as much of the sun and air as possible, but defended from frost.

In winter these plants should have but little water given them, for much wet is very injurious to them: in summer, when they are exposed to the open air, they must be frequently refreshed with water in dry weather; but at no time should have too much wet, for that will rot their roots.

These plants make a pretty variety in the green-house in winter, and when they are placed abroad in the summer with other green-house plants, they have a good effect, especially when they are grown to a large size. They generally flower the third year from seeds, but their flowers are produced so late in summer, that the seeds have seldom time to form before the cold comes on in the autumn; at least for some years past, as the seasons have been cold and moist; but in warm summers, the fourth sort will perfect seeds, if they stand in a warm sheltered situation.

The Galbanum of the shops is supposed to be procured from the third sort, for upon breaking the leaves, the juice which flows out from the wound, hath a strong odour of the Galbanum, which is a confirmation of it.

BUCKSHORN, or HARTSHORN. See PLANTAGO.

BUDDING. See INOCULATING.

BUDDLEJA. Houft. MSS. Lin. Gen. Plant. 131.

The CHARACTERS are,

It hath a small permanent empalement, which is slightly cut at the top into five acute parts. The flower is of one leaf, bell-shaped, and quadrifid, the petal being stretched out beyond the empalement; it hath four short stamina, which are placed at the divisions of the petal, terminated by short summits. The oblong germen is situated in the center, supporting a short style, crowned by an obtuse stigma; the germen afterward becomes an oblong capsule, having two cells filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and but one style.

The SPECIES are,

1. BUDDLEJA (*Americana*) foliis ovatis serratis oppositis floribus spicatis racemosis, caule fruticoso. *Buddleja with oval sawed leaves, growing opposite, flowers growing in branching spikes, and a shrubby stalk.* Buddleja fru-

tescens foliis conjugatis & serratis floribus spicatis luteis. Houft. MSS.

2. BUDDLEJA (*Occidentalis*) foliis lanceolatis acuminatis integerrimis oppositis, spicis interruptis. *Buddleja with pointed spear-shaped leaves which are entire, placed opposite, and broken spikes of flowers.* Buddleja frutescens foliis oblongis mucronatis, floribus spicatis albis. Houft. MSS.

The first sort grows naturally in Jamaica, and most of the other islands in America, where it rises to the height of ten or twelve feet, with a thick woody stem, covered with a grey bark; this sends out many branches toward the top, which come out opposite; as are also the leaves so placed, which are oval, and covered with a brown hairy down. At the end of the branches the flowers are produced in long close spikes, branching out in clusters, which are yellow, consisting of one leaf, cut into four segments; these are succeeded by oblong capsules, filled with small seeds. This was sent me by Dr. Houstoun, from Jamaica, in 1730, under the title Verbasco folio minor arbor, floribus spicatis luteis tetrapetalis seminibus singulis oblongis in singulis vasculis ficcis. Sloan. Cat. Jam. 139. But as this was a vague title, the doctor afterward constituted a new genus, and gave it the title of Buddleja, in memory of Mr. Buddle, an eminent English botanist.

The second sort the same gentleman sent me from Carthage, where it grows naturally. This is the Ophioxylon Americanum, foliis oblongis mucronatis, leviter serratis bardanæ instar, subtus lanuginosis. Pluk. Alm. 270. tab. 210. fig. s. and was by Plukenet supposed to be the same with the former, which was denied by Sir Hans Sloane in his History of Jamaica.

This sort rises much taller than the first, and divides into a great number of slender branches, which are covered with a russet hairy bark, garnished with long spear-shaped leaves, ending in sharp points: these grow opposite at every joint; at the end of the branches are produced branching spikes of white flowers, growing in whorls round the stalks, with small spaces between each. It hath long, narrow, spear-shaped leaves growing between the spikes, whereas those of the other sort are naked. The leaves of this are much thinner than those of the first sort, and have scarce any down on their under side; the spikes of flowers grow more erect, so form a large loose spike at the end of every branch.

The plants grow naturally in gullies or other low sheltered spots, in the West-Indies, their branches being too tender to resist the force of strong winds, so are rarely seen in open situations.

They are propagated by seeds, which should be obtained from the countries where they naturally grow, for they do not perfect them in England. These should be brought over in their capsules or pods, for those which are taken out before they are sent seldom grow. They should be sown in small pots, filled with rich light earth, and very lightly covered with the same; for as these seeds are very small, so if they are buried deep in the ground, they perish. The pots should be plunged into a moderate hot-bed, and must be every third or fourth day gently watered, being very careful not to wash the seeds out of the ground, by too hasty watering them. If the seeds are fresh and good, the plants will come up in about six weeks, provided they are sown in the spring; and if they grow kindly, will be large enough to transplant in about two months after. Then they should be carefully separated, and each planted into a small pot, filled with light rich earth, and plunged into the hot-bed again, observing to shade them from the sun until they have taken new root, as also to refresh them with water when they require it. After the plants have taken fresh root in the pots, there should be fresh air admitted to them every day, in proportion to the warmth of the season; they must also be frequently, but moderately, refreshed with water. If the plants thrive well, they will have filled these

small pots with their roots by the middle of August, at which time it will be proper to shift them into pots one size larger, that they may have time to take good root again, before the cold weather comes on. When these are new potted, the tan should be turned over to renew the heat; and if it is wanted, some fresh tan must be added to the bed, to encourage the roots of the plants. In this bed they may remain till autumn, when they must be removed into the stove, and plunged into the tan-bed; where they must constantly remain, for they are too tender to thrive in this country, if they are not so treated. During the winter they must have but little water, and should be kept warm; but in summer they should have fresh air admitted to them constantly when the weather is warm, and frequently sprinkled all over with water. With this management, the plants will flower the fourth year from seeds, and continue so to do every year after, and will make a good appearance in the stove.

BUGLOSSUM. See *ANCHUSA*, and *LYCOPSIS*.
BUGULA. Tourn. Inst. R. H. 208. tab. 98. Ajuga.
Lin. Gen. Plant. 624. Bugle.

The CHARACTERS are,

It hath a short permanent empalement of one leaf, which is slightly cut into five parts; the flower is of one leaf, of the lip kind, having an incurved cylindrical tube; the upper lip is very small, erect, and bifid; the under lip or beard is large, open, and divided into three obtuse segments, the middle being large, and the two sides small; it hath four erect stamina, two of which are longer than the upper lip, and two shorter, terminated by double summits. In the center is situated the four germen, supporting a slender style the length of the stamina, crowned by two slender stigma. The germen afterward become four naked seeds inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, intitled *Didynamia Gymnospermia*, the flower having two long, and two short stamina, and is succeeded by naked seeds.

The SPECIES are,

1. *BUGULA (Reptans) foliis caulinis semiamplexicaulis, stolonibus reptatricibus. Bugle whose leaves half embrace the stalks, and shoots which put out roots. Bugula. Dod. Pempt. 135. Common Bugle.*
2. *BUGULA (Decumbens) foliis oblongo-ovatis, caulibus decumbentibus, verticillis distantibus. Bugle with oblong oval leaves, declining stalks, and the whorls of flowers wide asunder. Bugula folio maximo flore pallide cæruleo. Boerh. Ind. alt. 1. 184.*
3. *BUGULA (Pyramidalis) foliis obtuse-dentatis, caule simplici. Bugle with blunt indented leaves, and a single stalk. Ajuga tetragono pyramidalis. Lin. Sp. Plant. 561.*
4. *BUGULA (Genevensis) foliis oblongis tomentosis, calycibus hirsutis. Bugle with oblong woolly leaves, and hairy flower-cups. Bugula carneo flore. Clus. Hist. 2. P. 43.*
5. *BUGULA (Orientalis) villosa, foliis ovato-dentatis sessilibus, floribus resupinatis. Hairy Bugle with oval indented leaves, placed close to the stalks, and inverted flowers. Bugula orientalis villosa flore inverso candido cum oris purpureis. Tourn. Cor. 14.*

The first sort grows naturally in woods, and shady moist places, in most parts of England, where it spreads and increases greatly by the side shoots, which put out roots at their joints. There are two varieties of this, one with a white, and the other a pale purple flower, which I observed growing in several parts of Westmoreland; but these do not differ in any other respect than in the colour of their flowers from the common, therefore I have only mentioned them as varieties.

The common Bugle is greatly esteemed as a vulnerary herb, and is used both internally and externally; it enters as an ingredient into the vulnerary decoctions of the surgeons, and is commended externally, applied to ulcers. This is constantly mixed with the vulnerary herbs, imported from Switzerland. It is intitled *Consolida Media*, or *Middle Confound*. As

this grows naturally wild in great plenty, so it is seldom admitted into gardens.

The second sort grows naturally on the Alps; the leaves of this are much longer than those of the common Bugle, the stalks are weaker, and decline on every side, and the whorls of flowers are much smaller, and are ranged at a greater distance. This is admitted into some gardens for the sake of variety, and propagates in plenty by its trailing stalks. This requires a moist shady situation.

The third sort grows naturally in France, Germany, and other countries, but is not a native in England. This grows about four or five inches high, with a single stalk, which is garnished with leaves at each joint, placed opposite; these are oval, and indented bluntly on their edges. The flowers grow in whorls round the stalks, and toward the top form a close thick spike, and are of a fine blue colour.

The fourth sort grows naturally in many parts of Europe. This approaches near to the common Bugle; but the leaves of this are woolly, and the flower-cups are very hairy, in which the chief difference consists. There are two varieties of this, one with a white, and the other a red flower.

The fifth sort was brought from the Levant by Dr. Tournefort, and is preserved by those who are curious in collecting rare plants. There are two or three varieties of it, which only differ in the colour of their flowers.

This sort requires a little protection in winter, therefore the plants should be planted in pots filled with a loamy soil, and placed in a shady situation in summer; but in the winter they must be removed under a common frame, where they may enjoy as much free air as possible in mild weather; but in hard frost should be covered, otherwise they will not live thro' the winter in this country, unless it proves very favourable.

This may be propagated by seeds, which should be sown soon after it is ripe, in a pot filled with loamy earth, and placed in a shady situation till autumn, when it should be removed under a frame, where it may be screened from hard frost. In the spring the plants will come up, which should be transplanted into separate pots as soon as they are strong enough to remove, and, in summer, placed in the shade, and treated as the old plants. It flowers in May, and the seeds ripen the latter end of July. It may also be increased by offsets, but this is a slow method, because the plants put out but few of them, especially while they are young, so the other method is chiefly practised.

All the other sorts are hardy enough, and are easily multiplied by their side shoots; these delight in a moist shady situation, where they are apt to spread too much, especially the two first sorts.

BULB [*Bulbus*, Lat. of Βολβός, Gr.] Bulbous roots are of two sorts, viz. tunicated (or coated) and squamous (or scaly.) A tunicated root consists of many coats, involving each other; as in the Onion, Tulip, &c. whose roots, if cut through the middle, plainly shew the several coats. A squamous root consists of many scales, lying over each other like tiles upon a house, or scales on fish; of this kind are the Lily, Martagon, &c.

BULBINE. See *ANTHERICUM*.

BULBOCASTANUM. See *BUNIUM*.

BULBOCODIUM. Tourn. Cor. 50. Lin. Gen. Plant. 368.

The CHARACTERS are,

The flower hath no empalement, it is funnel-shaped, and composed of six petals, which are concave, having long, narrow necks, connected at the mouth, but are spear-shaped above. It hath six awl-shaped stamina shorter than the petals, and are inserted in their middle, having incumbent summits. It hath an oval, blunt, three-cornered germen, supporting a slender style, crowned by three oblong erect stigma. The germen afterward becomes a triangular pointed capsule, having three cells, which are filled with angular seeds.

This

B U N

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. **BULBOCODIUM** (*Alpinum*) foliis subulato-linearibus. Prod. Leyd. 41. *Bulbocodium with narrow awl-shaped leaves.* Bulbocodium Alpinum juncifolium flore unico intus albo extus squallide rubente. Raii Syn. Ed. 3. p. 374.

2. **BULBOCODIUM** (*Vernum*) foliis lanceolatis. Prod. Leyd. 41. *Bulbocodium with spear-shaped leaves.* Colchicum vernum Hispanicum. C. B. P. 69.

The first sort grows naturally upon the Alps, and also upon Snowdon hills, in Wales. This hath a small bulbous root, which is covered with a rough hairy skin; from which arises a few long narrow leaves, somewhat like those of the Saffron, but narrower; in the middle of these the flower comes out, which stands on the top of the foot-stalk, growing erect, and is shaped like those of the Crocus, but smaller; the foot-stalk rises about three inches high, and hath four or five short narrow leaves placed alternately upon it below the flower. This flowers in March, and the seeds are ripe in May, when it grows in a garden, but where it grows naturally it is much later.

The second sort grows naturally in Spain, but hath been long cultivated in gardens. It hath a bulbous root, shaped like those of the Snowdrop, covered with a brown skin, sending out three or four spear-shaped concave leaves, between which comes out the flower, standing on a very short foot-stalk, composed of six petals, three standing on the outside, and three within between the other; these, when they first appear, are of a pale colour, but afterward change to a bright purple; when these decay, they are succeeded by triangular seed-vessels, which are full of small roundish seeds. It produces the flowers about the same time with the first.

These plants are propagated by offsets, in the same manner as other bulbous rooted flowers. The time to remove them, is soon after their leaves decay, but the roots may be kept out of the ground two months without prejudice at that season. They should not be removed oftener than every third year, for their roots do not multiply very fast, so by suffering them to remain, they will flower much stronger, and make a greater increase than if they are often taken up.

The first sort requires an eastern aspect, for if it hath too much sun, it will not thrive; but the second should have a warmer situation, so may be planted in a south border, and should have a fresh loamy soil, but not dunged. They may also be propagated by seeds, which should be sown in pots filled with fresh loamy earth in September, and the latter end of October, the pots should be placed under a frame, to protect them from severe frost; in the spring the plants will appear, when they may be removed out of the frame, and placed where they may have the morning sun, but screened from the south. In very dry weather, they should be refreshed now and then with a little water, while their leaves continue green; but, when these decay, the pots should be removed to a shady situation, where they may remain till autumn, observing to keep them clean from weeds. In October there should be a little fresh earth laid on the surface of the other, and the pots placed in shelter again till the following spring, when they must be treated in the same manner as the former year, till their leaves decay; then the roots should be carefully taken up, and transplanted into the borders of the flower-garden, treating them as the old roots; the spring following they will produce their flowers.

BUNIAS. Lin. Gen. Plant. 737.

The CHARACTERS are,

The empalement is composed of four oblong spreading leaves, which fall away. The flower hath four petals, placed in form of a cross, which are oval, and double the length of the empalement, joined at their base, and erect. It hath six stamina the length of the cup, two of which are opposite, and shorter than the other four, terminated by erect

B U N

summits, which are bifid at their base. In the center is situated an oblong germen, having no style, but crowned by an obtuse stigma. The germen afterward becomes an irregular, short, oval pod, with four angles, one or other of which is prominent and pointed, inclosing one or two roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradymania Siliquosa, the flowers having four long and two short stamina, and are succeeded by pods.

The SPECIES are,

1. **BUNIAS** (*Orientalis*) filiculis ovatis gibbis verrucosis. Lin. Sp. Plant. 670. *Bunias with oval convex pods, having protuberances.* Crambe Orientalis dentis leonis folio erucaginis facie. Tourn. Cor. 14.

2. **BUNIAS** (*Erucago*) filiculis tetragonis angulis bicristatis. Lin. Sp. Plant. *Bunias with short four-cornered pods, whose angles are doubly crested.* Erucago Monspelica siliqua quadrangula echinata. C. B. P. 99.

3. **BUNIAS** (*Cakile*) filiculis ovatis lævibus ancipitibus. Lin. Sp. Plant. 670. *Bunias with smooth oval pods, standing on each side the stalk.* Eruca maritima Italica, siliqua hastæ cuspidi simili. C. B. P. 99.

The first sort grows naturally in the Levant, from whence Dr. Tournefort sent the seeds to the Royal Garden at Paris. This hath a perennial root, and an annual stalk. It sends out many oblong leaves, which spread on every side near the ground, and are deeply jagged on their edges, like those of the Dandelion; from between these arise the stalks, which grow upwards of two feet high, sending out branches garnished at each joint by one oblong sharp-pointed leaf, eared at the base, where they sit close to the stalk. The branches are terminated by long loose spikes of yellow flowers, composed of four leaves, shaped like those of the Cabbage; these are succeeded by short, oval, rough pods, ending in a point, inclosing one round seed. It flowers in June, and the seeds are ripe in September.

The second sort grows naturally in the south of France and Italy; this is an annual plant, sending out many branches, which spread, and incline toward the ground; garnished with glaucous leaves, which are deeply divided into many segments, almost like those of Swines Cress. The flowers are produced singly from the wings of the leaves, toward the extremity of the branches; these are very small, of a pale yellowish colour, composed of four petals, placed in form of a cross, which are succeeded by short pods, which are crested on each side, containing one or two roundish seeds.

The third sort grows naturally about Montpellier; this is also an annual plant, sending out many oblong leaves near the root, which are hairy, deeply cut on each side, and spread on the ground; between these arise two or three stalks, which grow a foot and a half high, sending out several side branches, garnished with oblong rough leaves, indented on their edges; the upper part of the branches are destitute of leaves, but have flowers placed alternately on each side, standing on short foot-stalks, which are purple, and composed of four petals; these are succeeded by oval-pointed pods, containing one or two roundish seeds; there is a variety of this with narrow leaves.

These plants are all propagated by seed: the first sort may be sown where the plants are designed to remain, in the beginning of April, and when the plants come up, they should be thinned, leaving them two feet asunder, after which they will require no other care but to keep them clean from weeds. The second year they will produce flowers and seeds, and the roots will abide many years after.

The other two sorts must be sown where they are to remain, but the best time is in autumn, because those which are sown in the spring often fail, or do not come up time enough to perfect their seeds. These require no other culture but to keep them clean from weeds, and thin the plants to one foot distance.

BUNIU. Lin. Gen. Plant. 298. Bulbocastanum. Tourn. Inst. 312. tab. 161. Pig Nut, or Earth Nut.

The

The CHARACTERS are,
The great or general umbel is composed of near twenty rays or small umbels, which are short, and close together. The involucre of the great umbel is composed of many short narrow leaves, those of the smaller are the same, but are as long as the umbels. The proper empalement of the flower is scarce discernible. The rays of the great umbel are uniform. The flowers have five heart-shaped petals which are equal, and turn inward; they have five stamina which are shorter than the petals, terminated by single summits; the oblong germen is situated below the receptacle, supporting two reflexed styles, crowned by a blunt stigma. The germen afterward becomes an oval fruit, dividing in two parts, containing two oval seeds, plain on one side, and convex on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class of plants, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **BUNUM** (*Bulbocastanum*) bulbo globofo. Sauv. Monsp. 256. *Earth Nut with a globular root.* Bulbocastanum majus folio Apii. C. B. P. 162.
2. **BUNUM** (*Creticum*) radice turbinato. *Earth Nut with a turbinated root.* Bulbocastanum Creticum radice napi-formi. Tourn. Cor.
3. **BUNUM** (*Sexatile*) foliis tripartitis filiformibus linearibus. *Earth Nut with very narrow tripartite leaves.* Bulbocastanum minus saxatile Peucedani folio. Tourn. Inst. 312.

The first sort grows naturally in moist pastures, and in woods, in many parts of England. Of this there is a variety, supposed to be larger than that which grows commonly here, but I could never observe any essential difference between them; for in some places it is found much larger than in others, but when they have been transplanted into a garden, they have proved to be the same. This hath a tuberous solid root which lies deep in the ground, and puts out fibres from the bottom and sides. The leaves are finely cut, and lie near the ground. The stalk rises a foot and a half high, which is round, channelled, and solid, the lower part being naked; but above, where it branches out, there is one leaf placed below every branch, which are cut into finer segments than those below. The flowers are white, and shaped like those of other umbelliferous plants; the seeds are small, oblong, and when ripe are channelled. It flowers in May, and the seeds ripen in July, soon after which, the whole herb decays to the ground.

The roots of this sort are frequently dug up, and by the poorer sort of people are eaten raw, having much resemblance in taste to the Chestnut, from whence it had the title of Bulbocastanum. These roots, when boiled, are very pleasant and delicious, and are supposed to afford great nourishment. The swine are very fond of these roots, and will root them up, when they are admitted where they grow, and will soon become fat with feeding on them.

The second sort was discovered by Dr. Tournefort in the island of Crete, but it grows naturally in many other parts of the Levant. I received dried samples and seeds of this from Zant, where it grows plentifully.

The third sort I received from the Alps. This is a very low plant, seldom rising above six inches high. These plants delight to grow among grass, so cannot be made to thrive well long in a garden.

BUPHTHALMUM. Lin. Gen. Plant. 876. Asteriscus. Tourn. Inst. R. H. tab. 285. Ox-eye.

The CHARACTERS are,

The empalement is different in the several species. It hath a compound radiated flower, composed of hermaphrodite and female florets. The hermaphrodite florets compose the disk; these are funnel-shaped, and cut into five parts at the brim, which spread open, and have five slender stamina, which are short, terminated by cylindrical summits. In the center is situated an oval compressed germen, supporting a slender style, crowned by a thick stigma. The germen afterward becomes an oblong seed, whose bor-

der is cut into many parts; the female flowers which compose the rays (or border) are stretched out on one side like a tongue, which spreads open, and is indented at the top in three parts; these have no stamina, but a double-headed germen, supporting a slender style, crowned by two oblong stigma. The germen becomes a single compressed seed, cut on each side.

This genus of plants is ranged in the second section of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers having hermaphrodite and female florets, included in one common empalement, which are both fruitful.

The SPECIES are,

1. **BUPHTHALMUM** (*Helianthoides*) calycibus foliolis, foliis oppositis ovatis serratis triplinerviis caule herbaceo. Hort. Upsal. 264. *Ox-eye with a leafy empalement, oval sawed leaves placed opposite, having three veins, and an herbaceous stalk.* Chrysanthemum Scrophularia folio Americanum. Pluk. Alm. 99. tab. 22. fig. 1.
2. **BUPHTHALMUM** (*Grandiflorum*) foliis alternis lanceolatis subdenticulatis glabris, calycibus nudis caule herbaceo. Hort. Cliff. 415. *Ox-eye with smooth spear-shaped leaves (indented below,) naked empalements, and an herbaceous stalk.* Asteroides Alpina falicis folio glabro. Tourn. Cor. 51. tab. 487.
3. **BUPHTHALMUM** (*Salicifolium*) foliis alternis lanceolatis subserratis villosis calycibus nudis caule herbaceo. Hort. Cliff. 414. *Ox-eye with spear-shaped leaves placed alternate, sawed below and hairy, naked empalements, and an herbaceous stalk.* Aster luteus major, foliis succisæ. C. B. P. 266.
4. **BUPHTHALMUM** (*Spinosum*) calycibus acutè foliosis, ramis alternis, foliis lanceolatis amplexicaulibus integerrimis caule herbaceo. Hort. Cliff. 414. *Ox-eye with acute leafy empalements, branches placed alternate, and entire leaves embracing the stalks, which are herbaceous.* Asteriscus annuus, foliis ad florem rigidis. Tourn. Inst. 497.
5. **BUPHTHALMUM** (*Sessile*) floribus axillaribus calycibus foliosis, spinis terminalibus, foliis oblongis obtusis sessilibus. *Ox-eye with flowers coming from the forks of the branches, leafy empalements ending with spines, and oblong blunt leaves growing close to the branches.* Asteriscus annuus maritimus parulus. Tourn. Inst. 498.
6. **BUPHTHALMUM** (*Maritimum*) calycibus obtusè foliosis pedunculatis, ramis foliis alternis, spatulatis caule herbaceo. Hort. Cliff. 414. *Ox-eye with blunt leafy empalements, having foot-stalks, alternate leaves, and an herbaceous stalk.* Asteriscus maritimus perennis parulus. Tourn. Inst. 498.
7. **BUPHTHALMUM** (*Aquaticum*) calycibus obtusè foliosis sessilibus axillaribus, foliis alternis oblongis obtusis caule herbaceo. Hort. Cliff. 414. *Ox-eye with blunt leafy empalements sitting close to the forks of the stalk, oblong blunt leaves, and an herbaceous stalk.* Asteriscus annuus Lusitanicus odoratus. Boerh. Ind. alt. 105.
8. **BUPHTHALMUM** (*Frutescens*) foliis oppositis lanceolatis petiolatis bidentatis caule fruticoso. Hort. Cliff. 415. *Ox-eye with spear-shaped leaves growing opposite, having foot-stalks with two teeth, and a shrubby stalk.* Asteriscus frutescens leucii foliis fereceis & incanis. Hort. Elth. 44. tab. 38.
9. **BUPHTHALMUM** (*Arborecens*) foliis oppositis lanceolatis crassis, glabris utrinque viridibus floribus pedunculatis. *Ox-eye with thick, smooth, spear-shaped leaves growing opposite, green on both sides, flowers having foot-stalks, and a tree-like stalk.* Asteriscus frutescens leucii foliis viridibus & splendentibus. Hort. Elth. 43. tab. 38.
10. **BUPHTHALMUM** (*Incanum*) foliis oppositis lineari-lanceolatis crassis incanis, floribus sessilibus caule fruticoso. *Ox-eye with thick, hoary, narrow, spear-shaped leaves placed opposite, flowers growing close to the branches, and a shrubby stalk.* Asteriscus frutescens leucii foliis angustissimis fereceis & incanis. Ind. Hort. Chelf. 27.

The first sort grows naturally in North America. This hath a perennial root and an annual stalk: from the root there arises many stalks, in number proportional to the size of the roots; these grow upward of

six feet high, garnished at each joint with two oblong heart-shaped leaves placed opposite, which have three longitudinal veins, the base on one side being shorter than the other. The flowers come out at the extremity of the branches, having a leafy empalement; they are radiated, of a bright yellow colour, resembling a small Sun-flower, from whence the inhabitants of America have given it that appellation. It flowers in August, and when the autumns prove favourable, the seeds will ripen in England; but as it propagates easily by parting the roots, there are few persons who are solicitous about the seed. The best time to transplant and part the roots, is toward the end of October, when the stalks begin to decay. These should be removed every other year, to prevent their spreading too far; they are very hardy, so will thrive in any situation: but as the roots are apt to extend, they are not proper for the borders of small flower-gardens; but in large borders, on the sides of rural walks, or in spaces between shrubs, they will be ornamental during their season of flowering.

The second sort grows naturally on the Alps, as also in Austria, Italy, and the south of France. This hath a perennial root, and an annual stalk; it grows near two feet high, with slender branching stalks, garnished with oblong smooth leaves ending in a point; the flowers grow at the extremity of the branches, which are of a bright yellow colour, radiated round their borders like those of the Starwort. It flowers in June and July, and the seeds ripen in autumn. There are two or three varieties of this, differing in the breadth of their leaves and size of their flowers, but from the same seeds all these have been produced.

This sort is generally propagated by parting the roots, which may be performed at the same time, and in the same manner as is directed for the first sort. As this doth not spread so much as the former, a few roots may be allowed room in the borders of the flower-garden, especially those which have little sun, where these will continue a long time in flower.

The third sort is somewhat like the second, but the leaves are broader and obtuse; the stalks and leaves are also hairy, in which consists their difference. This flowers at the same time with the former, and is propagated in the same manner.

The fourth sort rises a foot and a half high: the stalks divide into many branches upward; the side branches rise much above the middle stalk, garnished with spear-shaped hairy leaves, placed alternately; the flowers are produced at the forks of the branches on short foot-stalks; the empalement consists of seven long, stiff, spear-shaped leaves, ending in a sharp point; these spread out beyond the rays of the flower in form of a star. The flower sits close upon the empalement, the border or rays being composed of many female florets, which have one side stretched out like a tongue, and indented at the end in three parts; the middle or disk of the flower is composed of hermaphrodite flowers, which are tubulous, funnel-shaped, and slightly indented in five parts at the brim; they are of a bright yellow colour, and are succeeded by oblong compressed seeds. The plants flower in June and July, and their seeds ripen in September, soon after which the plants decay.

The seeds of this should be sown the beginning of April, on open borders, where they are to remain, and will require no other care, but to keep them clear of weeds, and thin them to the distance of a foot and a half, that their branches may have room to spread. If the seeds are sown in the autumn, or are permitted to fall when ripe, the plants will come up soon after, and these will more certainly ripen seeds than the spring plants.

The fifth and seventh sorts are also annual plants, which grow naturally in the same countries with the last. These seldom grow more than one foot high in gardens, and where they are wild not so high, but send out many spreading alternate branches near the

root: their leaves, which are oblong, blunt, and hairy, are placed alternate, growing close to the branches without any foot-stalks; the leaves of the empalement of the fifth sort end in a very sharp spine, and are much broader at their base than either of the other. The flowers of all these have much the appearance of those of the last, but some are smaller, and those of the seventh sort have an agreeable odour. They flower at the same season, and are propagated in the same manner.

The sixth sort is a low perennial plant with a shrubby stalk, which rarely rises a foot high, sending out many spreading branches from the stem, garnished with hairy leaves, which are narrow at their base, but broad and roundish at their extremity; the flowers are produced at the end of the branches, they are yellow, and shaped like those of the former sorts, but the leaves of the empalement are soft and obtuse. These are seldom succeeded by seeds in England, but the plant is easily propagated by slips during the summer season; if the cuttings are planted in a bed of fresh loamy earth, and covered with a hand-glass, observing to shade them from the sun in the heat of the day, and frequently refreshed with water, they will take root in about six weeks, when they should be carefully taken up, and each planted in a separate small pot filled with fresh undunged earth, and placed in a shady situation till they have taken fresh root; after which they may be removed to a sheltered situation, where they may remain till the end of October, when they must be removed to a frame for the winter season, being too tender to live abroad in winter in this country; but as they only require protection from hard frosts, they will thrive better when they have a great share of air in mild weather, than if confined in a green-house; therefore the best method is to place them in a common frame, where they may be fully exposed in mild weather, but screened from the frost. This sort grows naturally in Sicily. It flowers great part of the year, which renders it the more valuable.

The eighth sort rises with several woody stems from the root, which grow to the height of eight or ten feet, garnished with leaves very unequal in size, some of which are narrow and long, others are broad and obtuse; these are intermixed, sometimes coming out at the same joint, and often at the intermediate one; they are soft, hoary, and placed opposite. The foot-stalks of the larger leaves have, on their upper side, near their base, two sharp teeth standing upward, and a little higher there are generally two or three more, growing on the edge of the leaves. The flowers are produced at the ends of the branches single; these are of a pale yellow colour, and have scaly empalements. It grows naturally in America. I received another sort of this from the Havannah, which was found growing naturally there by Dr. Houstoun, who sent it by the following title, *Chrysanthemum fruticosum maritimum, foliis glaucis oblongis, flore luco*. Sloan. Hist. Jam. 1. p. 125. The leaves of this are shorter and thicker than those of the tenth sort, and have no teeth on their foot-stalks, but in other respects are very like it; the plants are not so hardy. The eighth has been long preserved in the English gardens, and was originally brought from Virginia, as I was informed by the Bishop of London's gardener, who raised it in 1696 at Fulham.

The ninth sort grows naturally in the Bahama Islands, from whence I have several times received the seeds. This seldom grows much more than three feet high, sending out many stalks from the root, which are succulent, except near the root, where they are ligneous, garnished with thick, succulent, spear-shaped leaves placed opposite; the flowers are produced at the end of the branches upon foot-stalks which are two inches long. These flowers are larger than those of the eighth sort, of a bright yellow colour. They appear in July, August, and September, but often continue till the end of October.

The tenth sort grows in the Bahama islands, from whence I received the seeds. This sends out many slender stalks from the root, which rise near three feet high, garnished with long, narrow, thick, succulent leaves, which are very hoary, growing opposite, embracing the stalk at their base; the flowers are yellow, and are produced at the end of the shoots, having very short foot-stalks. These appear at the same time with those of the ninth sort.

As these three sorts do not perfect their seeds in this country, they are propagated by cuttings. They should be planted in July, when the plants have been for some time exposed to the open air, whereby their shoots will be hardened and better prepared to take root, than when they first come abroad. The cuttings should be planted in small pots filled with light loamy earth, and plunged into a very gentle warmth, observing to shade them from the sun in the heat of the day, and gently refresh them with water, but it must be given to them sparingly, for much wet will rot them. In about six weeks these will have taken root, when they must be gradually inured to bear the open air; and soon after they should be each planted in a separate small pot filled with light loamy earth, and placed in the shade until they have taken fresh root; after which they may be removed to a sheltered situation, where they may remain till the middle of October, when they must be removed in the green-house. The eighth sort being hardier than either of the other, may be placed in a common green-house; but the other two will thrive better in a warm glass-case, where they will receive more sun, and have a drier air. During the winter, they should have but little moisture, and in very mild weather they should have fresh air admitted to them. In the summer they must be placed abroad in a sheltered situation, and treated in the same manner as other exotic plants.

BUPLEUROIDES. See **PHYLLIS**.

BUPLEURUM [so called, from *Βούς*, *Bos*, and *πλευρόν*, *costa*, *latus*, because it is commonly believed, that if cows eat of it, it will burst their bellies.] Lin. Gen. Plant. 291. Hare's-ear.

The CHARACTERS are,

It is a plant with an umbellated flower; the rays of the principal umbel are thin, consisting of ten smaller umbels, which are erect and spread. The involucre of the great umbel is composed of many oval pointed leaves, those of the small have five. The flower hath five small heart-shaped petals, which are inflexed; it hath five slender stamina, which are terminated by roundish summits. The germen is situated below the flower, supporting two small reflexed styles, crowned by a small stigma. The germen after-ward becomes a roundish compressed fruit which is channelled, dividing in two parts, containing two oblong channelled seeds, convex on one side, and plain on the other. This genus of plants is ranged in the second section of Linnæus's fifth class, entitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. **BUPLEURUM** (*Rotundifolium*) involucris universalibus nullis, foliis perfoliatis. Hort. Upsal. 64. Hare's ear, whose greater umbel hath no involucre, and the stalks growing through the leaves. Perfoliata vulgarissima five arvensis. C. B. P. 277.
2. **BUPLEURUM** (*Angulosum*) involucellis pentaphyllis orbiculatis, universaliter triphylo ovato, foliis amplexicaulibus cordato-lanceolatis. Lin. Sp. Plant. 236. Hare's-ear with the small involucre composed of five orbicular leaves, the larger of three oval ones, and heart-shaped leaves embracing the stalk. Perfoliata Alpina angustifolia major folio anguloso. C. B. P.
3. **BUPLEURUM** (*Odontitis*) involucellis pentaphyllis acutis, universaliter triphylo, flosculo centrali altiore, ramis divaricatis. Lin. Sp. Plant. 237. Hare's-ear with smaller involucre, composed of five pointed leaves which are acute, those of the larger three-leaved, the flower in the center taller, and the branches spreading from each other. Perfoliata minor angustifolia, Bupleuri folio. C. B. P. 277.

4. **BUPLEURUM** (*Rigidum*) caule dichotomo subnudo, involucris minimis acutis. Lin. Sp. Plant. 238. Hare's-ear with stalks growing from the division of the branches, which have no leaves below, and a very small pointed involucre. Bupleurum folio rigido. C. B. P. 278.

5. **BUPLEURUM** (*Tenuissimum*) umbellis simplicibus alternis pentaphyllis subtrifloris. Lin. Sp. Plant. 238. Hare's-ear with single umbels growing alternate, and five leaves under each three flowers. Bupleurum angustissimo folio. C. B. P. 278.

6. **BUPLEURUM** (*Fruticosum*) frutescens, foliis obovatis integerrimis. Lin. Sp. Plant. 238. Shrubby Hare's-ear with oblong oval leaves which are entire. Bupleurum arborescens salicis folio. Tourn. Inst. 310. Sefeli Æthiopica frutex. Dod. Pempt. 312. Shrubby Hartwort of Æthiopia.

7. **BUPLEURUM** (*Difforme*) frutescens, foliis vernalibus decompositis planis incis, æstivalibus filiformibus angulatis trifidis. Lin. Sp. Plant. 238. Shrubby Hare's-ear, whose spring leaves are decomposed, plain, and cut, and the summer leaves are narrow, angular, and trifid. Bupleurum frutescens foliis ex uno puncto plurimis junceis tetragonis. Burman. Afr. 195. tab. 71. fol. 1.

The first sort grows naturally upon chalky land among wheat, in several parts of England, so is seldom admitted into gardens. The leaves and seeds of this plant are used in medicine; the herb is esteemed good for dissolving scrophulous tumours, and is by some used for internal ailments, ruptures, and bruises from a fall. It is called Thoroughwax in English.

The second, third, fourth, and fifth sorts are annual.

The fifth sort grows naturally in several parts of England, the others are natives of the Alps and Pyrenees; these are seldom cultivated but in botanic gardens for the sake of variety. Those who are desirous to have any of these species in their gardens, should sow their seeds in autumn, where the plants are designed to remain, for they do not bear transplanting well; and keep the plants clean from weeds, which is all the culture they require. They flower in June and July, and their seeds ripen in September.

The sixth sort hath a woody stem, which sends out many branches, so as to form a large head or bush, covered with a purplish bark, and garnished with oblong, oval, stiff leaves, which are very smooth, of a sea-green colour; the ends of the branches are terminated by umbels of yellow flowers somewhat like those of Fennel. These come out in August, but are seldom succeeded by perfect seeds in England. It grows naturally in the south of France and Italy, near the borders of the sea.

It is commonly known among gardeners by the title of Shrubby Æthiopian Hartwort, and is now propagated in the nursery-gardens for sale. This grows five or six feet high, forming a large regular bush, the leaves continuing green through the year render it more valuable. It is hardy, so will thrive in the open air, and may be intermixed with other evergreen shrubs of the same growth, in the front of taller trees, where their stems are designed to be excluded from sight. It is propagated by cuttings, which should be planted in pots filled with fresh loamy earth, and in winter sheltered under a hot-bed frame; in the spring the cuttings will put out roots, but they will not be fit to transplant till the autumn following; so the pots should be placed in a shady situation in summer, and in dry weather they must be refreshed with water. The young plants may be planted in a nursery-bed at two feet distance for a year or two to get strength, and then transplanted where they are to remain.

The seventh sort grows naturally at the Cape of Good Hope, from whence it was introduced to the gardens in Holland. This rises with a shrubby stalk to the height of five or six feet, sending out some side branches, which in the spring have their lower parts garnished with leaves composed of many small plain lobes; which are finely cut like those of Coriander,

BUR

of a sea-green colour, these leaves soon fall off, and the upper part of the branches are closely covered with long rush-like leaves having four angles, which come out in clusters from each joint. The flowers grow in spreading umbels at the extremity of the branches, which are small and of an herbaceous colour, and are succeeded by oblong channelled seeds.

This sort is commonly propagated by cuttings, which readily take root, if they are planted in April in pots filled with light earth, and plunged into a moderate hot-bed, and when they have taken root, they should be inured to the open air by degrees, and after they have obtained strength, may be planted each into a separate pot filled with light loamy earth, placing them in the shade, till they have taken fresh root, when they may be placed with other exotic plants in a sheltered situation, where they may remain till the autumn, when they must be removed into the green-house, and placed with such hardy plants as require a large share of air in mild weather, and only require a protection from frost.

If this plant is propagated by seeds, they should be sown in the autumn, soon after they are ripe, in pots filled with light earth, which must be sheltered under a frame in winter, and in the spring removed to a very gentle hot-bed, which will soon bring up the plants; these must be inured to bear the open air by degrees, and then treated in the same manner as those raised from cuttings. This plant flowers in July, and the seeds ripen in September.

BURMANNIA. Lin. Gen. 397. This genus was so titled by Dr. Linnæus, in honour to his friend Dr. Burman, professor of botany at Amsterdam.

The CHARACTERS are,

It hath a cylindrical coloured empalement of one leaf, having three longitudinal membranaceous angles, the flower hath three small oblong petals, situated in the mouth of the empalement, it hath six small stamina, the summits are at the mouth of the empalement, two at each; the germen is cylindrical, half the length of the empalement, supporting a slender style the length of the corolla, having three obtuse concave stigma: the empalement becomes a triangular cylindrical covering to the seeds, opening in three valves, having three cells filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, intitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. **BURMANNIA** (*Disticha*) *spica gemina*. Burm. Zeyl. 50. *Burmattia with a double spike of flowers.*
2. **BURMANNIA** (*Biflora*) *flore gemino*. Lin. Sp. 411. *Burmattia with two flowers.* *Burmattia scapo bifloræ.* Flor. Virg. 36.

The first sort grows naturally in Ceylon, in places covered with water most part of the year, the root is composed of many capillary fibres, from which come out six or eight narrow spear-shaped leaves, near two inches long, which are entire. The flower-stalk rises a span high, garnished with five or six narrow spear-shaped leaves which embrace it at their base; the stalk is terminated by a double spike of flowers spreading each way: these are garnished with small blue flowers, included in a swelling spatha, or sheath; these have each three short petals, six stamina, and one style; and in its native soil, the empalement of the flower becomes a triangular cover to the seeds.

The second sort grows naturally in Virginia and Carolina, in watery places, this hath a strong fibrous root, from which arise several oblong oval leaves, four or five inches long, which are smooth and entire; between these arises the foot-stalk of the flower, which is six or eight inches high, terminated by spikes of flowers, two growing in each spatha or sheath; these are blue, and in their native soil are succeeded by small seeds inclosed in the triangular empalement.

These plants are very difficult to preserve in gardens; for as they naturally grow in marshy places, which are covered with water great part of the year, they

BUT

will not thrive when planted in dry ground, and being too tender to live abroad in England, renders them very difficult to preserve; therefore whoever is desirous to have them, should plant them in pots, which should be plunged in troughs of water, so deep as to cover the surface of the mould therein about three inches. Those troughs in which the first sort is planted, should be placed in a warm stove, where they should constantly remain, being careful to supply the water as it may diminish in the troughs from time to time. The troughs in which the second sort is put, should be placed in a green-house in winter to protect the plants from frost, but in summer they may be exposed in the open air, with this management, if carefully attended to, the plants may be preserved, and sometimes may be brought to produce flowers.

BURNET. See **POTERIUM** and **SANGUISORBA**.

BURSA PASTORIS, Shepherds-pouch. This is a common weed in most parts of England; which propagates so fast by seeds, as not to be easily cleared when they are permitted to shed; for there are commonly four generations of this plant from seeds in a year, so fast does the seed ripen, and the plants come up; therefore it cannot be too soon or carefully rooted out of a garden.

BUTOMUS, [*Βέτομον*, of *βῆς*, an ox, and *τέμνω*, to cut, so called, because the leaves of it are so acute, that the tongue and lips of oxen, which are great lovers of this plant, are wounded by it, so that the blood issues forth: it is also called *Juncus Florida*, because it has the leaves of a Rush, and produces a fine bunch of flowers.] The Flowering-Rush, or Water-Gladiole.

The CHARACTERS are,

The flowers grow in a single umbel, having a short three leaved involucre. The flower hath six roundish concave petals, which are alternately smaller and more pointed, it hath nine awl-shaped stamina, six of which surround the other, and are terminated by double lamellated summits; it hath six oblong pointed germen, supporting a single stigma; the germen afterward become six oblong pointed capsules, having one cell filled with oblong seeds.

This genus of plants is ranged in the third section of Linnæus's ninth class, intitled Enneandria Hexagynia, the flower having nine stamina, and six germen.

We know but one SPECIES of this genus, viz.

BUTOMUS (*Umbellatus*). Fl. Lap. 159. *The Flowering-Rush, or Water-Gladiole.* *Juncus floridus major.* C. B. P. 112. *Greater Flowering-Rush.*

There are two varieties of this plant, one with a rose coloured flower, and the other with a white, but these are only accidental variations, therefore not to be enumerated as distinct species.

The Rose coloured sort is pretty common in standing waters, in many parts of England; the other is a variety of this, though less common with us near London. These plants may be propagated in boggy places, or by planting them in cisterns, which should be kept filled with water, that should have about a foot thickness of earth in the bottom, into which the roots should be planted, or the seed sown as soon as they are ripe; these, though common plants, yet produce very pretty flowers, and are worth propagating for variety, especially if in any part of the garden there should be conveniency for an artificial bog, or where there are ponds of standing water, as is many times the case, and persons are at a loss what to plant in such places, that may appear beautiful; whereas, if these, and a few more wild plants, which naturally grow in such places, were taken into the garden, they would have a very good effect in diversifying the several parts thereof.

There is another species, or at least a variety, of this plant, which is found growing near London, intermixed with the common sort, but not half so large either in leaf, stalk, or flower; but in other respects so like it, as to render it very difficult to be distinguished from it, for which reason I have not enumerated it; though many of the plants settled in the river

B U X

river Thames, close by the Chelsea garden, where they continued their usual small size many years.

BUXUS, the Box Tree.

The CHARACTERS are,

It hath male and female flowers on the same plant; the male flowers have a three-leaved, and the female a four-leaved empalement, which are concave. The male flowers have two, and the female three concave petals, which are larger than the empalement. The male flowers have four upright stamina, terminated by double erect summits with a rudiment of a germen, but no style or stigma: the female flowers have roundish, blunt, three-cornered germen, supporting three very short styles, crowned by obtuse prickly stigma. The empalement afterward becomes a roundish capsule, shaped like an inverted pottage pot, opening in three cells, each having two oblong seeds, which are cast forth by the elasticity of the pod when ripe.

This genus of plants is ranged in the fourth section of Linnaeus's twenty-first class, intitled Monœcia Tetrandria, there being male and female flowers on the same plant, and the male flowers having four stamina.

The SPECIES are.

1. *Buxus (Arborefcens) arborefcens, foliis ovatis. Tree Box with oval leaves. Buxus arborefcens. C. B. P. 232.*

2. *Buxus (Angustifolia) arborefcens foliis lanceolatis. Tree Box with spear-shaped leaves. Buxus angustifolia. Raii Syn. 445. Narrow-leaved Box.*

3. *Buxus (Suffruticosa) humilis foliis orbiculatis. Dwarf Box with round leaves. Buxus humilis. Dod. pempt. 782. Dwarf or Dutch Box.*

These are three certainly distinct species. The two sorts of Tree Box have been frequently raised from seeds, and constantly produced plants of the same kind from those the seeds were taken from; and the Dwarf Box will never rise to any considerable height with any culture, nor have I ever seen this sort flower, where the plants have been encouraged to grow many years in the greatest luxuriance. There are two or three varieties of the first sort, which are propagated in the gardens, one with yellow, and the other white striped leaves. The other hath the tops of the leaves only marked with yellow, which is called Tiped Box.

The first and second sorts grow in great plenty upon

B Y T

Box-hill, near Darking in Surry, where were formerly large trees of these kinds; but of late they have been pretty much destroyed, yet there are great numbers of the trees remaining, which are of a considerable bigness. The wood of this tree is very useful for turners, engravers, and mathematical instrument-makers, the wood being so hard, close, and ponderous, as to sink in water, which renders it very valuable for divers utensils.

All the varieties of the tree or large Box are proper to intermix in clumps of Evergreens, &c. where they add to the variety of such plantations; these may be propagated by planting the cuttings in autumn in a shady border, observing to keep them watered until they have taken root, when they may be transplanted into nurseries, till they are fit for the purposes intended. The best season for removing these trees is in October, though indeed, if care be used to take them up with a good ball of earth, they may be transplanted almost at any time, except in summer. These trees are a very great ornament to cold and barren soils, where few other things will grow; they may also be propagated by laying down the branches, or from seeds: the last being the best method to have them grow to be large, the seeds must be sown soon after they are ripe in a shady border, which must be duly watered in dry weather.

The Dwarf kind of Box is used for bordering flowerbeds or borders, for which purpose it far exceeds any other plant, it being subject to no injuries from cold or heat, and is of long duration, is very easily kept handsome, and, by the firmness of its rooting, keeps the mould in the borders from washing into the gravel-walks, more effectually than any plant whatever. This is increased by parting the roots, or planting the slips; but as it makes so great an increase of itself, and so easily parts, it is hardly worth while to plant the slips that have no roots. It is now become so common, that it may be purchased from the nurseries at a cheap rate.

The manner of planting this in edgings, &c. is so well understood by every working gardener, that it would be needless to mention any thing of that kind here.

BYTTNERIA. See **BASTERIA**.

C A C

C A A P E B A. See **C I S S A M P E L U S**.

C A B B A G E. See **B R A S S I C A**.

C A B I N E T, in a garden, is a conveniency which differs from an arbour, in this, that an arbour or summer-house is of great length, and arched over head in the form of a gallery; but a cabinet is either square, circular, or in cants, making a kind of salon, to be set at the ends, or in the middle of a long arbour.

C A C A L I A N T H E M U M. See **C A C A L I A**.

C A C A L I A, Foreign Coltsfoot.

The CHARACTERS are,

It hath compound flowers which are included in one common, cylindrical, scaly empalement: the flowers are tubulous and funnel-shaped, cut at the top into five parts which stand erect; these have each five short slender stamina, terminated by cylindrical summits. The germen is crowned with down, supporting a slender style, crowned by two oblong recurved stigma; the germen afterward becomes a single oblong seed, crowned with long down.

C A C

This genus of plants is ranged in the first section of Linnaeus's twenty-first class, intitled Syngenesia polygamia æqualis; these have all hermaphrodite flowers which are fertile.

The SPECIES are,

1. *CACALIA (Alpina) foliis reniformibus acutis denticulatis calycibus subtrifloris. Gouan. Monsp. 429. Cacalia with kidney-shaped leaves which are sharply indented, and generally three flowers in each empalement. Cacalia foliis crassis hirsutis. C. B. P. 197.*

2. *CACALIA (Glabra) foliis cutaneis acutioribus & glabris. C. B. P. 198. Cacalia with smooth leaves, having acute points. Cacalia glabro folio. Clus. Hist. 2. p. 115.*

3. *CACALIA (Suaveolens) caule herbaceo foliis hastato-sagittatis denticulatis, petiolis supernè dilatatis. Hort. Upsal. 254. Cacalia with an herbaceous stalk, spear-shaped indented leaves, and the upper side of the foot-stalk spreading. Cacalia Americana procerior, folio triangulari per basin auriculato, floribus albis. Edit. prior.*

4. **CACALIA**

4. *CACALIA (Atriplicifolia)* caule herbaceo, foliis subcordatis dentato-sinuatis, calycibus quinquefloris. Lin. Sp. Plant. 835. *Cacalia with an herbaceous stalk, heart-shaped sinuated leaves, and five florets in each empalement.* Nardus Americana procerior, foliis cæsius. Pluk. Alm. 251.
5. *CACALIA (Ficoides)* caule fruticoso, foliis compressis carnosius. Lin. Sp. Plant. 834. *Cacalia with a shrubby stalk, and fleshy compressed leaves.* Senecio Africanus arborefcens, ficoidis folio & facie. Com. Rar. Plant. 40.
6. *CACALIA (Kleinia)* caule fruticoso composito, foliis lanceolatis planis, petiolorum cicatricibus obsoletis. Lin. Sp. Plant. 834. *Cacalia with a compound shrubby stalk, plain spear-shaped leaves, and the foot-stalks leaving scars.* *Cacalianthemum folio nerii glauco.* Hort. Elth. 61. tab. 54.
7. *CACALIA (Papillaris)* caule fruticoso obvolutato spinis petiolaribus truncatis. Lin. Sp. Plant. 834. *Cacalia with a shrubby stalk, guarded on every side with broken rough foot-stalks.* *Cacalianthemum caudice papillari.* Hort. Elth. 63. tab. 55.
8. *CACALIA (Ante-euphorbium)* caule fruticoso, foliis ovato-oblongis, petiolis basi linea triplici deductis. Lin. Sp. Plant. 834. *Cacalia with a shrubby stalk, oblong oval leaves, and three lines connected to the base of the foot-stalk.* *Kleinia foliis carnosius planis ovato-oblongis.* Hort. Cliff. 395.
9. *CACALIA (Sonchifolia)* caule herbaceo, foliis lyratis amplexicaulibus dentatis. Lin. Sp. 1169. *Cacalia with an herbaceous stalk, and lyre-shaped indented leaves embracing the stalk.*
10. *CACALIA (Lutea)* caule herbaceo, foliis quinquepartitis acutis subtus glaucis, floribus terminalibus pedunculis longissimis. *Cacalia with an herbaceous stalk, leaves divided into five acute parts, glaucous on their under side, and flowers with long foot-stalks terminating the stalks.* The first sort grows naturally in Austria, and the Helvetian mountains, but is frequently preserved in curious gardens for the sake of variety. This hath a fleshy root which spreads in the ground, from which spring up many leaves, standing on single foot-stalks, shaped like those of Ground Ivy, but of a thicker texture, of a shining green on their upper side, but white on their under; between these arise the foot-stalk, which is round, branching toward the top, and grows a foot and a half high; under each division of the stalk is placed a single leaf, of the same shape with those below, but much smaller; the branches are terminated by purplish flowers, growing in a sort of umbel. These are succeeded by oblong seeds, crowned with down. The second sort hath the appearance of the first, but the leaves are almost heart-shaped, pointed, and sharply sawed on their edges, and on both sides very green; the stalks rise higher; the leaves upon the stalks have much longer foot-stalks than those of the first. The flowers of this are of a deeper purple colour. This grows naturally on the Alps. They flower toward the end of May, or the beginning of June. The third sort grows naturally in North America. This hath a perennial creeping root, which sends out many stalks, garnished with triangular spear-shaped leaves, sharply sawed on their edges, of a pale green on their under side, but a deep shining green above, placed alternately. The stalks rise to the height of seven or eight feet, and are terminated by umbels of white flowers, which are succeeded by oblong seeds crowned with down. It flowers in August, and the seeds ripen in October. This plant multiplies greatly by its spreading roots, and also by the seeds, which are spread to a great distance by the wind, the down which adheres to them being greatly assisting to their conveyance. The roots of this plant, which have been cast out of the Chelsea garden, have been carried by the tides to a great distance, where they have lodged on the banks of the river, and fastened themselves to the ground, and have increased so much, as that in a few years, it may appear as a native of this country. The stalks decay in autumn, and new ones arise in the spring.

The fourth sort is a native of America, but has been many years in some curious gardens. This hath a perennial root, and an annual stalk. The root is composed of many fleshy spreading tubers, sending out several strong stalks in the spring, which rise four or five feet high, garnished with roundish heart-shaped leaves, greatly indented on their edges, of a sea-green on their under side, but darker above, placed alternately the length of the stalks, which are terminated by umbels of yellowish herbaceous flowers, appearing in July and August, and are succeeded by seeds like those of the former sort, which ripen in October.

The first and second sorts are propagated by parting their roots, for they seldom produce good seeds in England. The best time to transplant and part their roots is in autumn. They require a loamy soil and a shady situation.

The third and fourth sorts propagate in great plenty, both by their spreading roots, and also their seeds. The roots should be transplanted in autumn, and require a moist soil and an open situation. If the seeds are permitted to scatter, the plants will come up in the spring without any care.

The fifth sort grows naturally at the Cape of Good Hope. This rises with strong round stalks to the height of seven or eight feet, which are woody at bottom, but soft and succulent upward, sending out many irregular branches, garnished more than half their length with thick, taper, succulent leaves, a little compressed on two sides, ending in points, covered with a whitish glaucous farina, which comes off when handled. These, when broken, emit a strong odour of turpentine, and are full of a viscous juice; at the extremity of the branches the flowers are produced in small umbels; they are white, tubulous, and cut into five parts at the top. The stigma which crowns the style is of a dark purple colour, and stands erect above the tube. The stamina are much shorter, and surround the oblong germen, which is situated in the center of the tube, and is crowned by long, white, hairy down. The germen afterward becomes an oblong seed, with the same down adhering to it; but these do not ripen in England. Some of the noblemen in France have the leaves of this plant pickled; in doing of which, they have a contrivance to preserve the white farina with which they are covered, and thereby render them very beautiful.

This sort is easily propagated by cuttings during the summer months: these should be cut from the plants and laid to dry a fortnight, that the wound may be healed over before they are planted. Most people plunge the pots, in which these are planted, into a moderate hot-bed, to forward their putting out roots; but if they are planted in June or July, they will root as well in the open air. I have frequently had the branches broken off by accident, and fallen on the ground, which have put out roots without any care. These branches may be kept six months out of the ground, and will take root if planted. This should have a light sandy earth, and in winter be placed in an airy glass-case, where they may enjoy the sun and air in mild weather, but must be protected from frost. During the winter season, the plants must have but little water; and in summer, when they are placed in the open air, it should not be given them too often, nor in great quantity, but treated like the Ficoides, and other succulent plants from the same country. It flowers usually in autumn; but is not constant to any season.

The sixth sort grows naturally in the Canary Islands, but has been long an inhabitant in the English gardens. This rises with a thick fleshy stem, divided at certain distances, as it were, in so many joints; each of these divisions swell much larger in the middle than they do at each end; the stalks divide into many irregular branches of the same form, which, toward their extremities, are garnished with long, narrow, spear-shaped leaves, of a glaucous colour, standing all round the stalks without order. As these fall

off, they leave a scar at the place, which always remains on the branches. The flowers are produced in large clusters, at the extremity of the branches, which are tubulous, and of a faint Carnation colour. They appear in August and September, but continue great part of October, and are not succeeded by seeds in this country. There have been stones and fossils dug up at a great depth in some parts of England, which have very perfect impressions of this plant upon them; from whence Dr. Woodward has supposed, the plants were lodged there at the universal deluge; and finding the impressions of many other plants and animals, which are natives of those islands, he concludes that the waters flowed hither from the south-west.

This plant has been called Cabbage-tree by the gardeners, I suppose from the resemblance which the stalks of it have to that of the Cabbage: others have titled it Carnation-tree, from the shape of the leaves, and colour of the flowers.

It is propagated by cuttings, in the same manner as the former sort, and the plants require the same culture; but must have a dry warm glass-case in winter, and very little water, being very subject to rot with wet. In summer they must be placed in the open air, in a warm sheltered situation, and in very dry weather refreshed moderately with water. With this management the plants will flower annually, and grow to the height of eight or ten feet.

The seventh sort resembles the sixth in its form and manner of growth, but the leaves are narrower and more succulent. These do not fall off entire like the other, but break off at the beginning of the foot-stalk, which are very strong and thick; and always continue, so that the main stalk of the plant, and the lower part of the branches, which are destitute of leaves, are set round on every side with these truncated foot-stalks. This sort hath not as yet produced any flowers in England. It is propagated in the same manner as the two former sorts, from cuttings, and the plants must be treated as hath been directed for the fifth sort, but require to be kept drier, both in winter and summer; therefore, in very wet seasons, the plants should be sheltered from hard rains, which often cause them to rot, when they are exposed thereto; but they require the open air in summer. This sort grows naturally at the Cape of Good Hope. The eighth sort has been long preserved in the English gardens, and was generally titled *Ante-euphorbium*, supposing it to have a contrary quality to the *Euphorbium*. This rises with many succulent stalks from the root, as large as a man's finger, which branches out upward, into many irregular stalks of the same form, but smaller, garnished with flat, oblong, succulent leaves, placed alternately round the branches; under each foot-stalk there are three lines or ribs, which run longitudinally through the branches joined together. This sort very rarely flowers in Europe, but is propagated by cuttings in the same manner as the fifth, and is equally hardy. It must have very little wet, especially in winter, and requires a dry, sandy, poor soil.

The ninth sort grows naturally in Ceylon, China, and also in the Spanish West-Indies, from whence I received the seeds. This sort seldom continues longer than to ripen its seeds. The stalk rises near two feet high, branching a little toward the top; the leaves are cut on their sides, and sinuated somewhat like those of Mustard, sitting close to the stalks, which are terminated by flowers formed almost in an umbel; these are in some plants yellow, and in others purple; they are small, and are succeeded by oblong oval seeds, having a feathery down. It flowers in July, and the seeds ripen in September, soon after which the plant decays.

This is propagated by seeds, which, if sown in the autumn soon after they are ripe in a pot, and plunged into the tan-bed in the stove, will more certainly succeed than those sown in the spring; but where there is not such conveniency, the seeds should be

sown on a hot-bed in the spring, and when the plants are fit to remove, they should be planted on another hot-bed to bring them forward, shading them till they have taken new root, after which air should be daily admitted to them in proportion to the warmth of the season. When the plants have acquired strength, they should be planted in pots, and either plunged into a moderate hot-bed under a deep frame, or placed in a glass-case, where they will flower and perfect their seeds.

The tenth sort grows naturally at St. Helena, from whence I received the plants: the roots of this sort spread and increase under the surface, so is easily propagated by parting the roots; the leaves arise immediately from the root, having very short foot-stalks; these are cut into five or six long acute segments almost to the midrib, the segments are also acutely cut on their sides in two or three places: the under side of the leaves are glaucous, their upper side of a dark green. The flower-stalk arises between the leaves immediately from the roots; this is naked, about eight inches high, terminated by six or eight yellow compound flowers standing on long foot-stalks, almost umbellatim; the flowers are succeeded by oblong seeds, which rarely ripen in England.

As this plant increases so fast by its root, there is little want of the seeds; therefore the roots may be parted either the beginning of September, or the latter end of March, and should be planted in pots filled with light earth, and plunged into the tan-bed in the stove, where it should be constantly kept, being too tender to thrive elsewhere in this climate.

CACAO. Tourn. Inst. R. H. 660. *Theobroma*. Lin. Gen. 806. The Chocolate-nut.

The CHARACTERS are,

The empalement is composed of five spear-shaped leaves, which spread open. The flower hath five petals, which are irregularly indented, and spread open; it hath five erect stamina, which are as long as the petals, terminated by pointed summits. In the center is placed the oval germen, supporting a single style, the length of the stamina, crowned by an erect stigma. The germen afterward becomes an oblong pod, ending in a point; which is woody, warted, and divided into five cells, which are filled with oval, compressed, fleshy seeds.

This genus of plants was constituted by father Plumier, who communicated the characters, which he had drawn in America, to Dr. Tournefort, who has inserted it in the Appendix to his Institutions. Dr. Linnæus has joined this to the *Guazuma* of Plumier, under the title of *Theobroma*; but as the fruit of these plants are very different from each other, I shall keep them under different genera.

We have but one SPECIES of this plant, which is,

CACAO. Clus. Exot. *The Chocolate-nut-tree*.

This tree is a native of America, and is found in great plenty in several places between the tropics, but particularly at Caracca and Carthage, on the river Amazons, in the isthmus of Darien, at Honduras, Guatemala, and Nicaragua. At all these places, it grows naturally without culture; but it is cultivated in many of the islands which are possessed by the French and Spaniards, and was formerly planted in some of the islands which are in the possession of the English; but it has been neglected for many years past, so that at present it is so scarce in those places, that the English are supplied with it by the French and Spaniards, who make the inhabitants pay them a good price for it; and as there is a great quantity of it consumed in England, consequently it must make an alteration in the balance of trade greatly to the prejudice of the English; which might be easily remedied, if the planters in our colonies were but the least industrious; since, as it formerly grew on those islands, so as to produce not only a sufficient quantity for their own consumption, but to supply Europe with great quantities, there can be no objection to the planting it in those islands again, especially in those situations where the sugar canes do not thrive to advantage.

I shall

I shall therefore subjoin the best account of this plant, and the culture which it requires in those countries, with the profits which have arisen from it to those who have planted some of these trees of late years, by way of experiment, in order to excite others to follow their example; and shall afterward give directions for cultivating it in England, by way of curiosity.

In making a plantation of Chocolate-trees, you must first be very careful in the choice of the situation, and the soil, otherwise there will be small hopes of success. As to the situation, it should be in a place where the trees may be protected from strong winds, to which if they are exposed, they will soon be destroyed: so that in such places where torrents of water have washed away the earth so as to leave broad and deep furrows (which the inhabitants of those islands call gullies,) these trees will thrive exceedingly: and as these are very frequently to be found in those islands, and many of them are of large extent, and not much cultivated, it may be a great improvement to some estates, which, at present, are of small value. The soil in these gullies is generally rich and moist, which is what these trees require; so that they will make great progress in these places, as hath been experienced by those persons, who have lately made trials of the plants in these situations; but where there are not a sufficient number of these gullies, choice should be made of a situation which is well sheltered by large trees; or, if there are not trees already grown, there should be three or four rows planted round the spot which is designed for the Chocolate-trees, of such sorts which are of quickest growth; and within these rows there should be some Plantain-trees, planted at proper distances, which being very quick of growth, and the leaves very large, will afford a kindly shelter to the young Chocolate-trees placed between them.

The Chocolate-trees which are cultivated, seldom grow to more than fourteen or fifteen feet in height, nor do they spread their branches very wide; so that if the Plantain-trees are placed in rows, about twenty four feet asunder, there will be room enough for two rows of Chocolate-trees between each row of Plantains; and if they are placed at ten feet distance in the rows, it will be sufficient room for them. Those trees which are found wild in uncultivated places, are generally of much larger growth, which may be occasioned by the other trees, amongst which these are found growing; for, being protected from the winds by those, they are not so much in danger therefrom, as those which are cultivated: and the other trees closely surrounding them, will naturally draw them up to a greater height: however, that is not a desirable quality in these trees; for the lower they are, the better the fruit may be gathered without hurting the trees; and the less they are exposed to the injuries of the weather; so that the inhabitants never desire to have their trees above twelve or fourteen feet high.

The soil upon which these trees thrive to most advantage, is a moist, rich, deep earth; for they generally send forth one tap root, which runs very deep into the ground, so that wherever they meet with a rocky bottom near the surface, they seldom thrive, nor are they of long continuance; but in a rich, deep, moist soil, they will produce fruit in pretty good plenty the third year from seed, and will continue fruitful for several years after.

Before the plantation is begun, the ground should be well prepared by digging it deep, and clearing it from the roots of the trees, and noxious plants, which, if suffered to remain in the ground, will shoot up again after the first rain, and greatly obstruct the growth of the plants; so that it will be almost impossible to clear the ground from those roots, after the Chocolate plants are come up, without greatly injuring them.

When the ground is thus prepared, the rows should be marked out by a line, where the nuts are to be

planted, so as that they may be placed in a quincunx order, at equal distance every way, or at least that the Plantain-trees between them may form a quincunx, with the two rows of Chocolate-trees, which are placed between each row of them.

In making a plantation of Chocolate-nut-trees, the nuts must be planted where the trees are to remain; for if the plants are transplanted, they seldom live; and those which survive it, will never make thriving trees; for, as I before observed, these trees have a tender tap root, which, if broke, or any way injured, the tree commonly decays.

The nuts should always be planted in a rainy season, or at least when it is cloudy weather, and some hopes of rain falling soon after. As the fruit ripens at two different seasons, viz. at Midsummer and at Christmas, the plantation may be made at either of those; but the chief care must be to choose such nuts as are perfectly ripe and sound, otherwise the whole trouble and expence will be lost. The manner of planting the nuts is, to make three holes in the ground, within two or three inches of each other, at the place where every tree is to stand; and into each of these holes should be one sound nut planted about two inches deep, covering them gently with earth. The reason for putting in three nuts at every place is, because they seldom all succeed; or, if most of them grow, the plants will not be all equally vigorous; so that when the plants have had one year's growth, it is very easy to draw up all the weak unpromising plants, and leave the most vigorous; but in doing this, great care should be had to the remaining plants, so as not to injure or disturb their roots in drawing the other out.

It is very proper to observe, that the Chocolate-nuts will not retain their growing faculty long after they are taken from the trees, so that there is no possibility of transporting them to any great distance for planting; nor should they be kept long out of the ground, in the natural places of their growth. There are some authors who have written the history of this tree, and distinguish three different sorts of the nuts, from the colour of their skins, one of which is of a whitish green colour, one of a deep red, and the third of a red and yellow colour; but these are not specifically different, but all arise from seeds of the same tree, as is the case of our Filberts, which differ in the colour of their skins, but are of the same colour within, and have the same taste. There are others, who would distinguish these nuts by their size and form, some being large and thick, others almost as flat as Beans; but these differences, I have been credibly informed, arise from some accident, as those trees which are young and vigorous, and grow upon a deep rich soil, will always produce larger and better nourished fruit, than those which stand on a shallow dry ground, and are unthriving trees: as will also the age of a tree make a great alteration in the size of the fruit; for old trees are generally observed to produce smaller and flatter nuts than those which are young, or than the same trees did bear while they were vigorous.

When the Chocolate-trees first appear above ground, they are very tender, and subject to great injuries from the strong winds, the scorching sun, or great droughts, for which reason the planters are obliged to guard against all these enemies, first, by making choice of a sheltered situation, or at least by planting trees to form a shelter; and, if possible, to have the plantation near a river, for the convenience of watering the plants the first season, until they have made strong roots, and are capable of drawing their nourishment from some depth in the earth, where they meet with moisture. But in order to shelter the plants from the scorching rays of the sun, they generally plant two rows of Cassada between each row of Chocolate-trees, which will grow about seven or eight feet high, and screen the young plants from the violence of the sun the first season; after which time, they will be in less danger of injury therefrom; and

and the following season, when the Cassada is taken up for use, the ground should be worked between the young plants, being very careful not to injure their roots by this operation. This method of planting the Cassada between the young Chocolate-trees, is of great advantage to the planter; for when the roots of the Cassada are taken up for use, it will defray the expence of keeping the ground clean from weeds, without which the young plants will come to nothing. The Plantains also, which will be fit to cut in about twelve months after planting, will defray the whole expence of preparing the ground, so that the produce of the Chocolate-trees will be neat profit; for as the Plantains produce fruit and decay, they will be succeeded by suckers, which will produce fruit in eight months after; whereby there will be a continual supply of food for the negroes, which will more than pay for keeping the ground wrought, and clear from weeds, until the Chocolate-trees begin to produce fruit, which is generally the third year after planting.

The planters usually set the Plantain-trees two or three months before the Chocolate-nuts are ripe, that they may be large enough to afford shelter to the young plants when they come up; and the Cassada is always planted a month or six weeks before the Chocolate-nuts, for the same reason. Some people plant Potatoes, others Cucumbers and Melons, or Water Melons, between the rows of Chocolate plants; which, they say, will prevent the weeds from rising to injure the young plants; for as all these trail on the ground, they occupy the whole surface, and prevent the weeds from growing: but where this is practised, it should be done with great caution, lest, by being over-covetous, you injure the young Chocolate-nuts so much, that they may never recover it; therefore great care should be taken to reduce the shoots of these plants, whenever they approach the Chocolate-trees; otherwise they will soon greatly injure, if not totally destroy them.

In about seven or eight days after the Chocolate-nuts are planted, the young plants will begin to appear above ground; when they should be carefully looked over, to see if any of them are attacked by insects; in which case, if the insects are not timely destroyed, they will soon devour all the young plants; or if there should be any weeds produced near the plants, they should be carefully cut down with a hoe; in doing which, great care should be taken that neither the tender shoot, nor the rind of the bark are injured. About twenty days after the plants have appeared, they will be five or six inches high, and have four or six leaves, according to the strength of the plants. These leaves are always produced by pairs, opposite to each other, as are also the branches; so that they make very regular handsome heads, if they are not injured by winds. In ten or twelve months they will be two feet and a half high, and have fourteen or sixteen leaves. By this time the Cassada, which was planted between the rows of Chocolate plants, will have large roots fit for use, therefore should be taken up; and the ground being then wrought over again, will greatly encourage the young plants.

In two years time the plants will have grown to the height of three feet and a half, or sometimes four feet, many of which will begin to flower; but the careful planters always pull off all these blossoms; for if they are permitted to remain to produce fruit, they will so much weaken the trees, that they seldom recover their strength again, so as to become vigorous. When these plants are two years and a half old, they will produce flowers again, some of which are often left to bear fruit; but the most curious planters pull off all these, and never leave any to produce fruit until the third year; and then but a few, in proportion to the strength of the trees; by which method, their trees always produce larger and better nourished fruit, than those which are suffered to bear a larger quantity, and will continue much longer in vigour. The fourth year they suffer their trees to bear

a moderate crop, but they generally pull off some flowers from those trees which are weak; that they may recover strength before they are too old.

From the time when the flowers fall off, to the maturity of the fruit, is about four months. It is easy to know when the fruit is ripe by the colour of the pods, which become yellow on the side next the sun. In gathering the fruit, they generally place a negro to each row of trees; who, being furnished with a basket, goes from tree to tree, and cuts off all those which are ripe, leaving the others for a longer time to ripen. When the basket is full, he carries the fruit, and lays it in a heap at one end of the plantation; where, after they have gathered the whole plantation, they cut the pods lengthways, and take out all the nuts, being careful to divest them of the pulp which closely adheres to them; and then they carry them to the house, where they lay them in large casks, or other vessels of wood, raised above ground, and cover them with leaves of the Indian Reed and mats, upon which they lay some boards, putting some stones thereon to keep them down close, in order to press the nuts. In these vessels the nuts are kept four or five days; during which time, they must be stirred and turned every morning; otherwise they will be in danger of perishing from the great fermentation they are usually in. In this time they change from being white to a dark red or brown colour. Without this fermentation, they say the nuts will not keep; but will sprout, if they are in a damp place, or shrivel and dry too much, if they are exposed to heat.

After the nuts have been thus fermented, they should be taken out of the vessels and spread on coarse cloths, where they may be exposed to the sun and wind; but at night, or in rainy weather, they must be taken under shelter, otherwise the damp will spoil them. If the weather proves fair, three days time will be long enough to dry them, provided they are carefully turned from time to time, that they may dry equally on every side. When they are perfectly dry, they may be put up in boxes or sacks, and preserved in a dry place until they are shipped off, or otherwise disposed of. The fresher these nuts are, the more oil is contained in them; so that the older they are, the less they are esteemed.

These trees do not produce their fruit on the young branches, or at their extremities, as most other trees do; but from the trunk, and the larger branches, come out the buds for flowers and fruit. While the trees are young, they do not produce their fruit in great plenty; for before the trees are eight years old, they reckon it a good crop to have twenty-eight or thirty pods on each tree at one gathering, especially that at Midsummer; which is always a much worse crop than the Christmas season, which is occasioned by the much greater drought of the spring; for the autumns being the rainy seasons, the Chocolate-trees produce a much greater quantity of fruit. When the trees are full grown and vigorous, they will sometimes produce two hundred, or two hundred and forty pods, at one season; which will make ten or twelve pounds of Chocolate, when dried; so that it is a very profitable commodity, and can be managed with very little charge, when compared with sugar. I have been credibly informed by a person of great worth and integrity, who resided some years in America, that he has seen as much Chocolate gathered from one tree in a year, as hath been worth thirty shillings sterling on the spot: so that the trouble of gathering and preparing for the market, being much less than for many other commodities which are manufactured in the British colonies, it is surprising it should be neglected; especially as it yields so large a share of sustenance to the wealthier inhabitants of those colonies, that they cannot live comfortably without it, and purchase it from the French and Spaniards at a considerable price; which in time must greatly impoverish the colonies.

The Chocolate-trees, if planted on a good soil, and properly taken care of, will continue vigorous and fruitful twenty-five or thirty years: therefore the charge of cultivating a plantation of these trees, must be much less than that of Sugar; for although the ground between the rows of plants will require to be often hoed and wrought, yet the first working of a ground to make a new plantation of Sugar, Indigo, Cassia, &c. is a larger expence than the after-workings are. Besides, Sugar-canes require as much labour in their cultivation, as any plant whatever; and since the insects which destroy the Sugar-canes, have spread so much in the British colonies, nothing is a more uncertain crop than Sugar; for which reason, I think it would be greatly worth those planters care, who are possessed of proper lands for the Chocolate-trees, to make some small trials at least, to be convinced of the truth of this fact.

The leaves of these trees being large, make a great litter upon the ground when they fall; but this is not injurious, but rather of service to the trees; for the surface of the ground being covered with them, they preserve the moisture in the ground, and prevent its evaporating; which is of great use to the young tender roots, which are just under the surface; and when the leaves are rotten, they may be buried in digging the ground, and it will serve as good manure. Some planters let the pods, in which the Chocolate is inclosed, lie and rot in a heap (after they have taken the nuts out) which they also spread on the ground instead of dung. Either of these manures are very good, provided they are well rotted before they are laid on the ground; and great care should be had, that no vermin should be carried on the plantation with the dung.

Besides the ordinary care of digging, hoeing, and manuring the plantations of Chocolate-trees, there is also another thing requisite in order to their doing well; which is, to prune the decayed branches off, and to take away small ill placed branches, wherever they are produced. But you should be cautious how this work is performed; for there should be no vigorous branches shortened, nor any large amputations made on these trees; because they abound with a soft, glutinous, milky juice, which will flow out for many days whenever they are wounded, which greatly weakens the trees. However, such branches whose extreme parts are decayed, should be cut off, to prevent the infection from proceeding farther; and such branches as are much decayed, should be taken off close to the stem of the tree; but this should be performed in dry weather, soon after the crop of fruit is gathered.

Some people may perhaps imagine, that what I have directed, is a tedious laborious work, and not to be performed by a few slaves: but this is a great mistake, for I have been credibly informed, that five or six negroes will cultivate a plantation of ten thousand of these trees, provided they are properly instructed; which is a small number, when compared to the quantity necessary to cultivate a Sugar plantation of the like extent of ground. And when the profits of both are compared, there will be a great difference: for, supposing we set the price of five shillings per annum, for the produce of each tree, when grown, (which I am of opinion is very moderate, considering what has been related;) then a plantation of ten thousand trees will produce twenty-five hundred pounds a year; which, managed by six or seven negroes, without the expence of furnaces, &c. is a much greater profit than, I think, can be drawn from any other production.

In order to cultivate this plant in Europe, by way of curiosity, it will be necessary to have the nuts planted into boxes of earth (in the countries where they grow) soon after they are ripe; because, if the nuts are sent over, they will lose their growing quality before they arrive. These boxes should be placed in a shady situation, and must be frequently watered, in order to forward the vegetation of the nuts. In

about a fortnight after the nuts are planted, the plants will begin to appear above ground; when they should be carefully watered in dry weather, and protected from the violent heat of the sun, which is very injurious to these plants, especially while they are young: they should also be kept very clear from weeds; which, if suffered to grow in the boxes, will soon overbear the plants and destroy them. When the plants are grown strong enough to transport, they should be shipped and placed where they may be screened from strong winds, salt water, and the violent heat of the sun. During their passage they must be frequently refreshed with water; but it must not be given them in great quantities, lest it rot the tender fibres of their roots, which will destroy the plants; and when they come into a cool latitude, they must be carefully protected from the cold, when they will not require so frequently to be watered: for in a moderate degree of heat, if they have gentle waterings once a week, it will be sufficient.

When the plants arrive in England, they should be carefully taken out of the boxes, and each transplanted into a separate pot filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, being careful to cover the glasses in the heat of the day, to screen the plants from the sun: they must also be frequently watered, but it must be done with caution, not to rot their roots. In this hot-bed the plants may remain till Michaelmas, when they must be removed into the bark-stove, and plunged into the tan, in the warmest part of the stove. During the winter season the plants must be frequently refreshed with water, but it must be given to them in small quantities, yet in summer they will require a more plentiful share. These plants are too tender to live in the open air in this country, even in the hottest season of the year; therefore must constantly remain in the bark-stove, observing in very warm weather to let in a large share of fresh air to them, and in winter to keep them very warm. As the plants increase in bulk, they should be shifted into larger pots; in doing of which, there must be particular care taken not to tear or bruise their roots, which often kills the plants; nor must they be placed in pots too large, because that is a slow, but sure death to them. The leaves of these plants must be frequently washed to clear them from filth, which they are subject to contract by remaining constantly in the house; and this becomes an harbour for small insects, which will infect the plants, and destroy them, if they are not timely washed off. If these rules are duly observed, the plants will thrive very well, and may produce flowers in this climate: but it will be very difficult to obtain fruit from them; for, being of a very tender nature, they are subject to many accidents in a cold country.

CACHRYS. Lin. Gen. Plant. 304.

The CHARACTERS are,

It hath an umbellated flower, the great or general umbel being composed of many smaller; the involucre of both is composed of many narrow spear-shaped leaves; the great umbel is uniform. The flower hath five spear-shaped, erect, equal petals. It hath five single stamina the length of the petals, terminated by single summits. The turbinate germen is situated under the receptacle, supporting two styles, crowned by roundish stigma. The empalement afterward becomes a large, oval, blunt fruit, dividing in two parts, each having one large fungous seed, convex on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. CACHRYS (*Trifidus*) foliis bipinatis, foliolis linearibus trifidis, seminibus lævibus. *Cachrys with bipinnated leaves, whose lobes are linear, and a smooth fruit.* Cachrys femine fungoso lævi, foliis ferulaceis. Mor. Umb. 62.
2. CACHRYS (*Sicula*) foliis bipinatis, foliolis linearibus acutis, seminibus sulcatis hispidis. Lin. Sp. 355. *Cachrys*

chrys with double winged leaves, whose lobes are linear, acute, and prickly furrowed seeds. Cachrys semine fungoso fulcato aspero, foliis peucedani latiusculis. Mor. Hist. 3. p. 267.

3. CACHRYS (*Libanotis*) foliis bipinnatis, foliolis acutis multifidis, seminibus sulcatis lævibus. Lin. Sp. 355. *Cachrys with double winged leaves, whose lobes are acute, multifid, and smooth furrowed seeds.* Cachrys semine fungoso fulcato plano minore, foliis peucedani angustis. Mor. Hist. 3. p. 267.
4. CACHRYS (*Linearia*) foliis pinnatis foliolis linearibus multifidis seminibus sulcatis planis. *Cachrys with very narrow, multifid, winged leaves, and a plain channelled fruit.* Cachrys semine fungoso fulcato plano majore foliis peucedani angustis. Mor. Umb. 62.
5. CACHRYS (*Hungarica*) foliorum impari lobato, hirsuto, semine fungoso fulcato plano. *Cachrys with hairy leaves, terminated with an odd lobe, and a plain, fungous, channelled seed.* Cachrys Hungarica Panacis folio. Tourn. Hist. 325.

The first sort hath a thick fleshy root which strikes deep in the ground, from which springs out many narrow winged leaves resembling those of Giant-fennel, which spread near the ground; from between these arise a hollow fungous stalk about two feet high, terminated by a large umbel of yellow flowers, which are succeeded by oval, smooth, fungous fruit, dividing into two parts, each inclosing an oblong seed.

The second sort hath a large, firm, sweet-smelling root, which sends out several pinnated leaves like those of Hog's-fennel, but shorter. The stalk is smooth jointed, and rises four or five feet high, which is terminated by large umbels of yellow flowers like those of Dill; these are succeeded by oblong, fungous, channelled seeds, which are prickly.

The third sort hath a thick fleshy root like Fennel, which runs deep into the ground, sending out several narrow pinnated leaves, ending in many points; between these arise a smooth jointed stalk about three feet high, which is terminated by large umbels of flowers like those of the former sort, which are succeeded by smaller fungous plain seeds which are furrowed.

The fourth sort hath very thick roots which strike deep in the ground, sending out very narrow winged leaves like those of Hog's-fennel. The stalk rises five or six feet high, and is jointed like those of Fennel, terminated by large umbels of yellow flowers, which are succeeded by large, oval, fungous seeds, which are deeply furrowed.

The fifth sort has a thick fungous root, from which shoot out many winged leaves, having large hairy lobes placed alternate, terminated by an odd one: the stalk is hollow, rising four feet high, terminated by an umbel of yellow flowers like those of the former sorts. This grows naturally in Hungary.

The first sort grows naturally in the south of France and Spain; the second and third in Italy; the fourth in Sicily. They flower in June, and their seeds ripen in autumn.

These plants are all propagated by seeds, which should be sown soon after they are ripe; for if they are kept out of the ground till the following spring, they often miscarry, and when they succeed, they never come up until the spring after; so that by sowing them in autumn, a whole year is saved, and the seeds seldom miscarry. These seeds should be sown on a shady border, where the plants are to remain; for the plants having long tap roots, will not bear transplanting so well as many other kinds. The distance to be observed for the sowing of their seeds should be three feet apart; so that if each kind is sown in a drill, when the plants are come up, they may be thinned, leaving two of the most promising plants of each kind to remain. These plants will begin to appear early in April, when they must be carefully cleared from weeds; and in dry weather, if they are gently watered while young, it will greatly promote their growth; after which time they will require no farther care but to keep them clean from

weeds, and every spring to dig the ground carefully between them, so as not to injure the roots.

These plants decay to the ground every autumn, and come up again in the spring: they commonly flower in the beginning of June, and their seeds are ripe in September. Their roots sometimes run down three or four feet deep in the earth, provided the soil be light, and are often as large as Parsneps. They will continue many years, and if the soil is moist and rich, they will annually produce good seeds; but when they grow on a dry soil, the flowers commonly fall away, and are not succeeded by seeds.

There is but little to be said of the uses of this genus of plants; the Hungarians in the neighbourhood of Erlaw, and those who border on Transylvania, Servia, &c. eat the root of the fifth species in a scarcity of corn, for want of other bread.

CACTUS. Lin. Gen. Plant. 539. Melocactus. Tourn. Append.

This genus was first titled Melocarduus, and also Echinomelocactus, or Hedgehog Melon-thistle; but these names being compounded, Dr. Linnæus has changed the name to Cactus, and has added to this genus, the Cereus and Opuntia.

The CHARACTERS are,

The empalement of the flower is of one leaf, tubulous, short, and cut into six parts. The flower is composed of six petals, which spread open at the top, and rests upon the embryo; it hath six long slender stamina, which are terminated by erect summits. The oval germen, which is situated below the petals, supports a cylindrical style, crowned by a blunt stigma; afterward becomes a pyramidal fleshy fruit with one cell, filled with small angular seeds surrounded with pulp.

This genus of plants is ranged in the first section of Linnæus's twelfth class, intitled Icosandria Monogynia. This class includes those plants whose flowers have from twelve to twenty stamina; which, with the corolla, are fastened to the inner side of the empalement.

The SPECIES are,

1. CACTUS (*Melocactus*) subrotundus quatuordecem angularis. Hort. Cliff. 181. *Roundish Cactus with fourteen angles.* Melocactus Indiae occidentalis. C. B. P. 384. Commonly called Great Melon-thistle.
2. CACTUS (*Intortus*) subrotundus quinquedecem angularis, angulis in spiram intortis, spinis erectis. *Roundish Cactus or Melon-thistle, with fifteen angles spirally twisted, and erect spines.* Melocactus purpureis striis in spiram intortis. Plum. Cat.
3. CACTUS (*Recurvus*) subrotundus quinquedecem angularis, spinis latis recurvis creberrimis. *Roundish Melon-thistle with fifteen angles, having broad recurved spines set very close.*
4. CACTUS (*Mamillaris*) subrotundus tectus tuberculis ovatis barbatis. Hort. Cliff. 181. *Roundish Cactus closely covered with bearded tubercles.* Melocactus Americana minor. Boerh. Ind. alt. 2. 84. *Smaller American Melon-thistle.*
6. CACTUS (*Proliferus*) proliferus subrotundus, tectus tuberculis ovatis barbatis longis albidis. *Roundish prolific Cactus, with oval tubercles closely joined, having long white beards, commonly called Small Childing Melon-thistle.*

These plants are natives of the West-Indies, where there are more sorts than are here enumerated, if persons of skill were to examine those islands. There have been about four of the large kinds brought to England, some of which have been crowned with a prickly brown cap, in form of one of those fur caps, which are worn by the Turks; and others, which have been destitute of these caps, although the plants were full as large as those which had them; therefore some persons have supposed them to be distinct species, especially since these have been many years preserved in the gardens, and no appearance of any caps as yet have been produced; but as these have been rarely propagated by seeds, it is difficult to determine if they are essentially different. Those which have these caps, produce their fruit in circles round the upper

upper part of the cap; whereas, the smaller sorts produce their fruit from between the tubercles, round the middle of the plant: and in some figures of the larger sorts of these plants, the fruit is represented as coming out near the crown of the plant; so that if a skilful botanist was to examine these plants in the places of their growth, there would probably be found a much greater variety of them than is at present known.

These strange plants commonly grow upon the steep sides of rocks in the warmest parts of America, where they seem to be thrust out of the apertures, having little or no earth to support them; their roots shooting down into the fissures of the rock to a considerable depth, so that it is troublesome to get the plants up, especially as they are so strongly armed with thorns as to render it very dangerous to handle them; and as these plants delight in those rocky places, they seldom live long when they are transplanted into better soil by the inhabitants of those islands.

The great sorts were some years since brought over to England in much greater plenty than of late; but then the greatest part of them were destroyed, by the unskilfulness of those persons who had the care of them in the voyage; for, by giving them water, they generally caused them to rot before they were taken out of the ships; and some of those which have appeared to be found, have been so replete with moisture, as to rot soon after they have been placed in the stoves; therefore whoever proposes to bring these plants from abroad, should be very careful to take up their roots as entire as possible, and to plant them in tubs filled with stones and rubbish, mixing very little earth with it, and to plant three or four plants in each tub, in proportion to their sizes; for if they are placed close together, it will save room; and as they do not increase their growth during their passage, there need not be any room allowed them for that purpose. There should be several pretty large holes bored thro' the bottom of these tubs, to let the moisture pass off; and if these plants are planted in the tubs a month before they are put on board the ship, they will in that time have made new roots, which will be the most secure method to have them succeed; but, during their continuance in the country, they should have no water given them, and after they are put on board the ship, they must not have any moisture whatever; therefore it will be a good method to cover the plants with tarpaulin, to keep off the spray of the sea in bad weather, and expose them at all times to the open air when the sea is calm. By observing these directions, the plants may be brought to England in good health, provided they are brought in summer.

Some of the large sort which have been brought to England, have been more than a yard in circumference, and two feet and a half high, including their caps; but I have been informed by several persons who have resided in the West-Indies, that there are plants near twice as large.

The third sort was brought into England by the late Dr. William Houstoun, who procured the plants from Mexico; but as they were long in their passage, and had received wet, they were decayed before they arrived in England; but from the remains of them which were left, they appeared to be the most singular of all the species yet known. This has two orders of thorns; one of which are strait, and set on at the joints in clusters, spreading out from the center each way like a star; and in the middle of each cluster is produced one broad flat thorn near two inches in length, which stands erect, and is recurved at the point, and is of a brownish red colour. These thorns are, by the inhabitants of Mexico, set in gold or silver, and made use of for picking their teeth, and the plant is by them called *Vismaga*, i. e. tooth-pick.

The sort with spiral ribs, as also that with white spines, I received from Antigua, with the common sort; but whether these are only accidental varieties, arising from the same seeds, or real different species,

I cannot take upon me to determine; since, in this country, they are very rarely propagated by seeds; nor could I observe, in the several years that I have had these plants under my care, there was the least disposition in either of them to produce fruit; when, at the same time, the common large sort produced plenty of fruit out of their caps every year, from the seeds of which I have raised some young plants; but although some of these have grown to a considerable size, yet none of them have as yet produced caps, therefore no fruit can be yet expected from them.

The fifth sort produces quantities of fruit annually; and as the seeds grow very readily, it is now very common in those gardens where there are stoves to keep them; for if the fruit is permitted to drop upon the earth of the pots, and that is not disturbed, there will plenty of plants come up without any farther trouble; and these seedling plants may be taken up as soon as they are of a proper size to remove, and planted six or seven of them into a small halfpenny pot, where they may stand one year; by which time they will be large enough to be each planted into a separate pot, and afterward they will make great progress, especially if they are plunged into a hot-bed of tanners bark in summer; for although this sort is much more hardy than the large kind, and may be preserved in a moderate stove, yet the plants will not make near the progress as those which are kept in a greater degree of heat. This sort will continue many years with proper care, and the plants will grow to be a foot high or more; but when they are so tall, the lower part of them is not so tightly, their green being decayed, and the spines changed to a dark dirty colour, they appear as if dead, so that the upper part of these old plants only seem to have life; whereas the plants of the middling size appear healthy from top to bottom. The flowers of this sort appear in July and August, and are succeeded by the fruit quite round the plant, which are of a fine scarlet colour, and continue fresh upon the plants through the winter, which renders them very beautiful at that season. And in the spring, when the fruit shrivels and becomes dry, the seeds will be ripe, and may then be rubbed out, and sown upon the surface of the earth in small pots, which should be plunged into a hot-bed of tanners bark to bring up the plants.

The sixth sort is but little larger than the fifth, growing nearly in the same form; but this produces a great number of young plants from the sides, by which it is increased. This sort produces tufts of a soft white down upon the knobs, and also between them at every joint, which makes the whole plant appear as if it was covered with fine cotton. The flowers of this sort are produced from between the knobs round the sides of the plants, which are in shape and colour very much like those of the fifth sort, but larger. These flowers are not succeeded by any fruit, at least all those which I have under my care, have not produced any, although they have produced plenty of flowers for some years; but from the same places where the flowers have appeared, there have been young plants thrust out the following season. These young plants I have taken off, and after laying them to dry for two or three days, I have planted them, and they have succeeded very well.

All the species of this genus are plants of a singular structure, but especially the larger kinds of them, which appear like a large fleshy green Melon, with deep ribs, set all over with strong sharp thorns; and when the plants are cut through the middle, their inside is nothing but a soft, green, fleshy substance, very full of moisture. And I have been assured by persons of credit, who have lived in the West-Indies, that in times of great drought, the cattle repair to the barren rocks, which are covered with these plants, and after having ripped up the large plants with their horns, so as to tear off the outside skin with the thorns, they have greedily devoured all the fleshy moist parts of the plants, which has afforded them both meat
and

and drink; but how any animal should ever attack plants which are so well defended by strong thorns, which are as hard and stiff as whalebone, or any other bony substance, is difficult to conceive; nor could any thing but distress for moisture ever have tempted them to venture amongst these troublesome plants to search for relief, since they must encounter with many difficulties, before they could find a method of dislodging the thorns.

The fruit of all the sorts of Melon-thistles, are frequently eaten by the inhabitants of the West-Indies; there is scarce any difference in the fruits of all the kinds I have yet seen, either in size, shape, colour, or taste. They are about three quarters of an inch in length, of a taper form, drawing to a point at the bottom toward the plant, but blunt at the top, where the empalement of the flower was situated. The taste is an agreeable acid, which, in a hot country, must render the fruit more grateful.

All the sorts of these plants require a very good stove to preserve them through the winter in England, nor should they be exposed to the open air in summer; for although they may continue fair to outward appearance, when they have been some time exposed abroad, yet they will imbibe moisture, which will cause them to rot soon after they are removed into the stove. And this is frequently the case of those plants which are brought from abroad, which have a fair healthy appearance many times at their first arrival, but soon after decay, and this will happen very suddenly. Scarce any appearance of disorder will be seen, till the whole plant is killed; which, in a few hours time, has often been the fate of those plants, when they have been placed in the stove.

If these plants are plunged into a hot-bed of tanners bark in summer, it will greatly forward them in their growth; but when this is practised, there should be scarce any water given to the plants, for the moisture which they will imbibe from the fermentation of the tan, will be sufficient for them, and more would cause them to rot. The best method to preserve all the large kinds is, in winter, to place the pots, either upon the tops of the flues, or, at least, very near them, that they may have the warmest place of the stove; and during that season, never to give them any water; but when the season comes for leaving out the fire in the stove, to remove them into a bed of tanners bark, which will soon set them in a growing state, and recover their verdure. The soil in which these should be planted, must be of a sandy nature, and if mixed with some dry lime rubbish, it will be still better. In the bottom of the pots should be placed some stones, in order to drain off any moisture which may be in the earth; for as these plants naturally grow upon the hot dry burning rocks which have no earth, and, were it not for these plants, would be absolutely barren, we must imitate their natural soil as near as possible, making some allowance for the difference of climates.

The great sorts may be propagated by seeds, which must be sown and managed as hath been directed for the smaller sort; but as the plants which are raised from seeds in England, will be some years in arriving to any considerable size, it will be much the best way to procure some plants from the West-Indies; and if the plants arrive here in any of the summer months, so as that there may be time for them to get new root before the cold comes on in autumn, the plants will more certainly succeed. When the plants come over, it will be proper to take them out of the earth as soon as possible, and lay them in the stove upon the shelves, to dry for a fortnight or three weeks; and when they are planted, they should be plunged into a good warm bed of tanners bark, to promote their making new roots. In this bed they may remain till the beginning of October, when they must be removed into the stove, and treated in the manner before directed.

The two small sorts propagate so fast in England, as to render it unnecessary to send for plants of these kinds from abroad; for whoever hath a mind to be

plentifully stocked with them, may be soon supplied with the fifth sort from seeds; and the sixth from the young plants which are thrust out from the side of the old.

CÆSALPINA. Plum. Nov. Gen. 9. Brasiletto.

This plant was so named by father Plumier, who discovered it in America, in honour of Andreas Cæsalpinus, an eminent botanist, and one of the first writers on a method of classing plants.

The CHARACTERS are,

It hath a quinquiesid pitcher-shaped empalement, the under lobe being large. The flower hath five almost equal petals, of the butterfly kind. It hath ten declining stamina which are distinct, and terminated by roundish summits, and an oblong germen supporting a single style the length of the stamina, crowned by a blunt stigma. The empalement afterward becomes an oblong compressed pod, with one cell inclosing three or four compressed seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flower having ten separate stamina and one style.

The SPECIES are,

1. CÆSALPINA (*Brasiliensis*) foliis duplicato-pinnatis, foliolis emarginatis, floribus decandris. *Cæsalpina with doubly winged leaves, whose small leaves are indented at the end, and flowers with ten stamina. Pseudo-santalum croceum. Sloan. Hist. Jam. Vol. II. p. 184. Saffron-coloured Bastard Saunders, commonly called Brasiletto.*
2. CÆSALPINA (*Arista*) foliis duplicato-pinnatis foliolis ovatis integerrimis floribus pentandris. *Cæsalpina with doubly winged leaves, whose small leaves are oval and entire, and flowers with five stamina. Cæsalpina polypylla aculis horrida. Plum. Nov. Gen. 28.*

The first sort is the tree which affords the Brasiletto wood, which is much used in dyeing. It grows naturally in the warmest parts of America, from whence the wood is imported for the dyers; and the demand for it has been so great, that there are no large trees left in any of the British colonies, the biggest scarce exceeding eight inches in diameter, and fifteen feet in height. It hath very slender branches, which are armed with recurved thorns. The leaves are winged, branching out into many divisions, each being garnished with small oval lobes which are indented at the top, and are placed opposite. The foot-stalks of the flowers come out from the side of the branches, and are terminated by a loose pyramidal spike of white flowers, which are shaped somewhat like those of the butterfly kind, having ten stamina which are much longer than the petals, and terminated by roundish yellow summits. The germen afterward becomes a long compressed pod with one cell, inclosing several oval flat seeds.

The second sort grows naturally in the same countries with the first, but is of larger size: it sends out many weak irregular branches, armed with short, strong, upright thorns. The leaves branch out in the same manner as the first, but the lobes (or small leaves) are oval and entire. The flowers are produced in long spikes like those of the former, but are variegated with red; these have each but five stamina, therefore, according to Linnæus's system, should not be ranged in this class; but as in all the other characters they agree, I have continued them together.

Dr. Linnæus has joined these two species together, in which he has been followed by Dr. Burman; but if either of them had seen the plants, they could not have committed this mistake. To this genus Linnæus has added two other species, one of which is a *Guilandina*, and the other a *Bauhinia*: to the latter he has added the Synonyme of *Colutea Veræ Crucis Vescicaria*, which is a plant totally different, being a genuine *Colutea*. I received this from the late Dr. Houstoun, who found it growing naturally at La Vera Cruz, in New Spain.

These plants are propagated by seeds, which should be sown in small pots filled with light rich earth early in the spring, and plunged into a hot-bed of tanners bark, observing to water the earth as often as it ap-

pears dry; in order to promote the vegetation of the seeds; and if the nights should prove cold, the glasses of the hot-bed should be covered with mats, to keep the bed in a moderate warmth. In about six weeks after, the plants will begin to appear, when they must be carefully cleared from weeds, and frequently refreshed with water; and, in warm weather, the glasses of the hot-bed should be raised in the middle of the day, to admit fresh air to the plants, which will greatly strengthen them, otherwise they are apt to draw up weak. When the plants are about three inches high, they should be carefully taken out of the pots, and each transplanted into a separate small pot filled with fresh light earth, and plunged into the hot-bed again, observing to water them, and screen them from the heat of the sun until they have taken new root; after which time, the glasses of the hot-bed should be raised every day, in proportion to the heat of the weather, to admit fresh air to the plants. In this hot-bed the plants may remain till autumn, when they should be removed into the stove, and plunged into the bark-bed, where they may have room to grow. These plants being tender, should always be kept in the bark-stove, and have a moderate share of heat in the winter, and being placed among other tender exotic plants of the same country, will afford an agreeable variety.

CAINITO. See CHRYSOPHYLLUM.

CAKILE, Sea Rocket. See BUNIAS.

CALABA, Indian Maltich-tree. See CORNUS.

CALAMINTHA. See MELISSA.

CALCEOLUS, Ladies Slipper. See CYPRIPE-
DIUM.

CALCITRAPA. See CENTAUREA.

CALEA.

The CHARACTERS are,

It hath a uniform compound flower, composed of many equal hermaphrodite florets, included in a loose imbricated empalement; the florets are tubulous, divided into five segments; they have each five stamina with cylindrical summits, and an oblong germen, with a slender style the length of the corolla, crowned by two recurved stigma. The florets are succeeded by an oblong seed, crowned with a hairy down, having a chaffy substance between each seed.

This genus of plants is ranged in the first order of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis, the flowers being composed of hermaphrodite flowers.

The SPECIES are,

1. CALEA (*Oppositifolia*) corymbus congestis, pedunculis longissimis, foliis lanceolatis, caule herbaceo. Amoen. Acad. 5. p. 404. *Calea with a close corymbus, very long foot-stalks to the flowers, spear-shaped leaves, and an herbaceous stalk.* Santolina Americana foliis oblongis integris, floribus albis. Houft. MSS.

2. CALEA (*Amellus*) floribus subpaniculatis, calycibus brevibus, seminibus nudis, foliis ovato-lanceolatis petiolatis. Amoen. Acad. 5. p. 404. *Calea with flowers in panicles, short empalements, naked seeds, and oval spear-shaped leaves on foot-stalks.* Santolina scandens Americana Lauri foliis, floribus racemosis. Houft. MSS.

These plants grow naturally in Jamaica. The first hath an upright herbaceous stalk three feet high, garnished with entire spear-shaped leaves, placed opposite at the joints; the stalk is terminated by three foot-stalks, one in the middle, and one on each side, supporting a small corymbus of white flowers closely joined together.

The second sort hath ligneous branches, which spread over the neighbouring plants, and rise eight or ten feet high, garnished with thick spear-shaped leaves placed opposite; from these stalks are put out many side branches, garnished with smaller leaves placed opposite, and terminated by panicles of yellow flowers, having short empalements: these are succeeded by naked seeds inclosed in the flower-cup.

These plants are both propagated by seeds, which should be sown upon a hot-bed early in the spring;

when the plants come up, they should be tenderly treated while young, admitting fresh air to them daily in proportion to the warmth of the season, giving them water frequently, but sparingly; when they have obtained strength enough to be removed, those of the first sort should be transplanted into another hot-bed, allowing them four inches distance. The plants of the second sort should be put into small pots plunged into the tan-bed, observing to shade them until they have taken new root; after which they should be treated in the same manner as other tender exotic plants, watering them frequently in warm weather, and admitting fresh air to them daily. When the plants of the first sort have grown so strong as to meet, they should be carefully planted in pots, and removed either into the stove or glass-case, where they may remain to ripen seeds, after which they soon die. The plants of the second sort will live many years if they are preserved in the bark-stove, but they are too tender to thrive in the open air in this country; however, they should have plenty of fresh air admitted to them in summer when the weather is warm.

CALENDULA. Lin. Gen. Plant. 885. Marigold.

The CHARACTERS are,

It hath a compound radiated flower, consisting of hermaphrodite and female florets, included in a common single empalement, the border or rays being composed of female florets, which are stretched out on one side like a tongue; these have no stamina, but an oblong three-cornered germen, supporting a slender style, crowned by two reflexed stigma. The hermaphrodite florets, which compose the disk, are tubulous and quinquesid, having five short slender stamina, terminated by cylindrical summits. The germen is situated under the petal, supporting a slender style, crowned by an obtuse bifid stigma. These florets are barren, but the female florets are each succeeded by one oblong incurved seed, with angular membranes.

This genus of plants is ranged in the fourth section of Linnæus's nineteenth class, intitled Syngenesia Polygamia necessaria; in which are included all those plants which have hermaphrodite barren flowers in the disk, and fruitful female flowers in the border.

The SPECIES are,

1. CALENDULA (*Arvensis*) seminibus cymbiformibus muricatis incurvatis. Flor. Suec. 711. *Marigold with rough boat-shaped seeds.* Caltha arvensis. C. B. P. 275.

2. CALENDULA (*Santia*) seminibus urceolatis obovatis lævibus, calycibus submuricatis. Lin. Sp. 1304. *Marigold with smooth pitcher-shaped leaves, and a rough empalement.* Caltha media folio longo cinereo, flore pallido. Bobart. *Middle Marigold with a long Ash-coloured leaf, and a pale flower.*

3. CALENDULA (*Officinalis*) seminibus cymbiformibus muricatis, incurvatis omnibus. Lin. Sp. 1304. *Marigold with boat-shaped, prickly, incurved seeds.* Caltha vulgaris. C. B. P. 275. *Common Marigold.*

4. CALENDULA (*Pluvialis*) foliis lanceolatis sinuato-denticulatis caule folioso, pedunculis filiformibus. Hort. Upsal. 274. *Marigold with spear-shaped indented leaves, and slender foot-stalks.* Caltha Africana flore intus albo extus violaceo. Tourn. Inst. R. H. 499.

5. CALENDULA (*Nudicaulis*) foliis lanceolatis sinuato-dentatis caule subnudo. Lin. Sp. Plant. 922. *Marigold with sinuated, indented, spear-shaped leaves, and a naked stalk.* Caltha Africana flore intus albo, extus leviter violaceo, semine plano cordato. Boerh. Ind. alt. 1. p. 113.

6. CALENDULA (*Hybrida*) foliis lanceolatis dentatis caule folioso, pedunculis superne incrassatis. Hort. Upsal. 274. *Marigold with indented spear-shaped leaves, and the upper part of the foot-stalk swelling.* Cardispermum Africanum pubescens foliis incisus parvo flore. Vaill. Mem. Acad. Sc. 1724.

7. CALENDULA (*Graminifolia*) foliis linearibus subintegerrimis caule subnudo. Lin. Sp. Plant. 922. *Marigold with narrow entire leaves, and a naked stalk.* Caltha Africana foliis Croci angustis, florum petalis externe purpurascens, interne albis. Boerh. Ind. alt. 1. p. 113.

8. *CALENDULA (Fruticosa)* foliis obovatis subdentatis, caule fruticoso. Amœn. Acad. 5. p. 25. *Marigold with obverse, oval, indented leaves, and a shrubby stalk.*
9. *CALENDULA (Decumbens)* foliis oppositis pinnatifidis asperis, subtus incanis, ramis decumbentis, pedunculis nudis. *Marigold with rough pinnatifid leaves growing opposite, which are white on their under side, trailing branches, and naked foot-stalks.* *Caltha Americana* foliis laciniatis flore luteo. Houst. MSS.
10. *CALENDULA (Americana)* caule erecto ramoso, foliis oblongis oppositis hirsutis, floribus lateralibus. *Marigold with an upright branching stalk, oblong hairy leaves growing opposite, and flowers proceeding from the sides of the stalk.* *Caltha Americana erecta, & hirsuta,* flore parvo ochroleuco. Houst. MSS.

The first sort grows naturally in the south of France, Spain, and Italy; it rises with a slender branching stalk, which spreads near the ground, and is garnished with narrow, spear-shaped, hairy leaves, which half surround the stalk at their base; the flowers are produced at the extremity of the branches upon long naked foot-stalks. They are very small, and of a pale yellow colour; the rays are very narrow, as are also the leaves of the empalement. The seeds are long, narrow, and on their outside armed with prickles. The root is annual, and perishes soon after the seeds are ripe. If the seeds of this plant are permitted to scatter, there will be a fresh supply of young plants: so that from May, when the flowers first appear, till the frost puts a stop to them, there will be a succession of plants in flower. There are several botanists who suppose the common Marigold, which is cultivated in gardens, to be only a variety of this, arising from culture; but I have cultivated this in the garden more than forty years, without finding the least alteration in it, therefore cannot doubt of its being a distinct species.

The second sort I gathered in the garden at Leyden, where it had been several years cultivated without altering; the leaves of this sort are smooth, and much larger than those of the former, but not so large as those of the common Marigold; the flowers are also of a middle size between them, and are of a very pale yellow colour. This is also an annual plant. If the seeds are permitted to scatter, there will be a constant supply of young plants come up.

The third sort is the common Marigold, which is cultivated for use in the gardens; this is so well known, as to require no description. Of this there are the following varieties; the common single; the double flowering; the largest very double flower; the double Lemon-coloured flower; the greater and smaller childing Marigold.

These varieties are supposed to have been originally obtained from the seeds of the common Marigold, but most of these differences continue, if the seeds are properly saved; nor have I ever observed the common sort approaching to either of these, where they have been long cultivated in the greatest plenty; but as the two childing Marigolds, and the largest double, are subject to degenerate, where care is not taken in saving their seeds, I conclude they are not distinct species. The best way to preserve these varieties, is to pull up all those plants, whose flowers are less double, as soon as they appear, that they may not impregnate the others with their farina, and save the seeds from the largest and most double flowers; and the childing sort should be sown by itself in a separate part of the garden, and the seeds saved from the large center flowers only, not from the small ones which come from the empalement of the other, for the seeds of these are apt to change.

The seeds of these may be sown in March or April, where the plants are to remain, and will require no other culture but to keep them clean from weeds, and to thin the plants where they are too close, leaving them ten inches asunder, that their branches may have room to spread. These plants will begin to flower in June, and continue in flower until the frost kills them. The seeds ripen in August and Septem-

ber, which, if permitted to scatter, will furnish a supply of young plants in the spring; but as these will be a mixture of bad and good, the best method is to save the best seeds, and sow each of the varieties distinct, which is the sure way to have them in perfection. The flowers of the common Marigold are used in the kitchen.

The fourth sort grows naturally at the Cape of Good Hope. This plant is annual, and perishes soon after the seeds are perfected.

The lower leaves are oblong, spear-shaped, and deeply indented on their edges; they are fleshy, and of a pale green colour. The stalks are produced on every side the root, which decline toward the ground, and are from six to eight inches long, garnished with leaves from the bottom, to within two inches of the top. The leaves on the stalks are much narrower, and more indented than those at the root. The upper part of the stalk is very slender, upon which rests one flower, shaped like those of the common Marigold, having a purple bottom; and the rays (or border) of the flower are of a Violet-colour on their outside, and of a pure white within; these open when the sun shines, but shut up in the evening, and remain so in cloudy weather. When the flower decays, the pedicle (or foot-stalk) becomes weak, and the head hangs down, during the formation and growth of the seeds; but when they are fully ripe, the foot-stalk raises itself again, and the heads of the seeds stand upright.

The fifth sort is a native of the Cape of Good Hope. This is also an annual plant, and has much the appearance of the former, but the leaves are more deeply indented on their edges; the stalks grow about the same length as the former; the flower is a little smaller, and the outside of the rays are of a fainter purple colour. The seeds of this are flat and heart-shaped, but those of the former are long and narrow.

The sixth sort was brought from the same country with the two former, and is also an annual plant; the leaves of this are much longer than those of either of the former sorts, and broader at the end; they are regularly indented near the root, but those on the stalks have but few and shallow indentures. The stalks of this sort are much longer and thicker than those of the former; and at the top, just below the flower, swell larger than at the bottom; the flower is smaller than those of the other sorts, but is of the same colour. These plants flower in June, July, and August, and their seeds ripen about six weeks after; so that they must be gathered at different times as they come to maturity.

The seeds of these plants should be sown in the spring in the borders of the garden where the plants are designed to remain, for they do not bear transplanting well; therefore they may be treated in the same manner, and sown at the same time, with Candy Tuft, Venus Looking Glass, and other hardy annual plants, putting four or five seeds in each patch; if they all grow, there should not be more than two plants left in each patch: after this, they require no farther care but to keep them clean from weeds. If the seeds of these plants are permitted to scatter, the plants will come up the following spring without care, and these will flower earlier than those which are sown in the spring.

The seventh sort is also a native of the same country. This is a perennial plant, which divides near the root into several tufted heads, which are closely covered with long grassy leaves coming out on every side without order; some of these have one or two indentures on their edges, but the most part are entire. From between the leaves arise naked foot-stalks about nine inches long, sustaining one flower at the top, which is about the size of the common Marigold, having a purple bottom; the rays are also purple without, but of a pure white within. These expand when the sun shines, but always close in the evening, and in cloudy weather. The general season of their beauty

beauty is in April and May, when they have the greatest number of flowers upon them; but there is commonly a succession of flowers late in the autumn, though not in so great plenty. This sort doth not often produce good seeds in Europe, but it is easily propagated by slips taken off from the heads, in the same manner as is practised for Thrift. They may be planted any time in summer, in pots filled with light fresh earth, which may be plunged into a very moderate hot-bed, to forward their putting out roots; or otherwise the pots may be sunk in the ground up to their rims, and covered with a Melon-glass, which, in the middle of summer, will answer full as well, but in the spring or autumn, the former method is to be preferred: when these are planted, the glasses must be shaded in the heat of the day, and the slips must be frequently refreshed with water, but it must not be given them too liberally, for much wet will rot them: after they have got strong roots, they should be each planted into separate small pots, filled with fresh light earth, and placed in a shady situation, till they have taken fresh root, when they may be placed in the open air, in a sheltered situation, where they may remain till autumn, and then should be placed in a dry, airy, glass-case, for the winter season, or under a common hot-bed frame; for these plants do not thrive in artificial heat, they only require protection from frost and wet, and should enjoy the air at all times when the weather is mild. The seeds of this sort are heart-shaped, like those of the fifth. I have sometimes had one or two heads of them ripen in a season, but this is very rare; and if the seeds are not sown in autumn, they seldom grow.

The eighth sort has been of late years introduced into the Dutch gardens from the Cape of Good Hope. This was sent me by Dr. Van Royen, professor of botany at Leyden, some years past. It hath a slender, shrubby, perennial stalk, which rises to the height of seven or eight feet, but requires support; this sends out a great number of weak branches, from the bottom to the top, which hang downward, unless they are supported; they are garnished with oval leaves, having short flat foot-stalks; most of these are slightly indented toward the top, and many of them are entire; they are of a shining green colour on their upper side, but paler underneath; the flowers come out at the end of the branches, on short naked foot-stalks, and are in size and colour like those of the sixth sort; these are sometimes succeeded by flat heart shaped seeds. The flowers appear during the summer months.

This is easily propagated by cuttings, which may be planted any time in summer in a shady border, or otherwise shaded with mats in the heat of the day: in five or six weeks, these will have taken root, when they should be carefully taken up, and each put into a separate pot, filled with light sandy earth, but not dunged, and placed in the shade till they have taken fresh root; then they may be placed with other hardy exotic plants in a sheltered situation where they may remain till the frost begins, when they must be removed into the green-house, placing them near the windows that they may enjoy the free air, for this plant only requires protection from frost. The earth in which these are planted, should be light, but very poor, for in rich earth they grow too luxuriant, and seldom flower.

The ninth sort was sent me from La Vera Cruz, in New Spain, by the late Dr. Houstoun, where he found it growing naturally in great plenty. This sends out many herbaceous stalks from the root, which are hairy, and trail upon the ground. The leaves are placed by pairs opposite; these are long, narrow, and indented on their edges in two or three places opposite to each other, so as to appear like three, five, or seven lobes: they are rough, and of a deep green on their upper side, but hoary on their under, covered with slender hairs. From the divisions of the branches and the wings of the leaves, come out long naked foot-stalks, terminated by single yellow

flowers, about the size of those of the Field Daisy; which are succeeded by long, flat, rough seeds. It grows naturally in poor sandy ground, and flowers in the spring. This plant is annual; the seeds must be sown in the spring upon a hot-bed, and when the plants are fit to remove, they should be planted in pots filled with light sandy earth, and plunged into a hot-bed of tanners bark, observing to shade them until they have taken new root; then they must have air admitted to them every day, in proportion to the warmth of the season, and treated in the same manner as other tender plants from the same countries. With this management, the plants will flower in August, and the seeds ripen in October.

The tenth sort rises with an upright stalk about eight inches high, sending out slender stiff branches on every side, those near the ground being much longer than the upper; these are garnished with oblong hairy leaves without foot-stalks, placed opposite. From the wings of the stalk, arises the foot-stalk of the flower, having two small leaves placed opposite, just below the flower, which hath a single empalement, like the other species. The flowers are of a yellowish white colour. This sort was sent me with the former from La Vera Cruz, by the same gentleman. It is an annual plant, and requires the same treatment as the former sort.

CALF'S SNOOT. See ANTIRRHINUM.

CALLA. Lin. Gen. Plant. 917. Wake Robin, or Ethiopian Arum.

The CHARACTERS are,

It hath a large open spathe of one leaf, which is oval and heart-shaped, ending in a point, it is coloured and permanent, and a single upright spadix, to which the flowers and fruit adhere. This hath male and female flowers, intermixed toward the upper part of the club (or spadix.) The male flowers consist of many very short stamina, terminated by small yellowish summits; the female flowers have a compressed style, resting upon an obtuse germen, crowned by a pointed stigma. These flowers, at their first appearance, have a short green empalement which soon falls off, leaving the style naked. The germen afterward becomes a globular pulpy fruit, compressed on two sides, inclosing two or three obtuse seeds.

This genus of plants is ranged in the seventh section of Linnæus's twentieth class, intitled Gynandria Polyandria. This class includes those plants whose male and female flowers are intermixed; and this section, those whose male parts have many stamina.

The SPECIES are,

1. CALLA (*Æthiopica*) foliis sagitato-cordatis, spathe cucullatâ, spadice supernè masculo. Hort. Cliff. 436. *Calla with arrow-headed heart-shaped leaves, a hooded spathe or sheath, and male flowers situated on the upper part of the spadix.* Arum Africanum flore albo odorato. Par. Bat. Prod.
2. CALLA (*Palustris*) foliis cordatis, spathe plana, spadice unidique hermaphrodito. Hort. Cliff. 436. *Calla with heart-shaped leaves, a plain sheath, and every part of the foot-stalk hath hermaphrodite flowers.* Dracunculus aquatilis. Dod. Pempt. 330.
3. CALLA (*Orientalis*) foliis ovatis. Gron. Orient. 282. *Calla with oval leaves.* Arum minus Orientale, rotundioribus foliis. Mor. Hist. 3. p. 544.

This plant hath thick, fleshy, tuberous roots, which are covered with a thin brown skin, and strike down many strong fleshy fibres into the ground. The leaves arise in clusters, having foot-stalks more than a foot long, which are green and succulent. The leaves are shaped like the point of an arrow, they are eight or nine inches in length, and of a shining green, ending in a sharp point, which turns backward; between the leaves arise the foot-stalk of the flower, which is thick, smooth, of the same colour as the leaves, and rises above them, and is terminated by a single flower, shaped like those of the Arum; the hood or spathe being twisted at the bottom, spreads open at the top, and is of a pure white colour. In the center of this is situated the spadix or club, which is of an herbaceous yellow colour, upon which the small her-

baceous

baceous flowers are placed, and so closely joined, as that the male and female parts are very difficult to distinguish, without the assistance of glasses. When these fade, part of those which are situated at the top of the club, are succeeded by roundish fleshy berries compressed on two sides, each containing two or three seeds.

This plant grows naturally at the Cape of Good Hope, but has been long an inhabitant in the English gardens. It propagates very fast by offsets, which should be taken off the latter end of August, at which time the old leaves decay; but this plant is never destitute of leaves, for before the old ones decay, there are young leaves produced, which advance in height all the winter; but at this season the roots are in their most inactive state. These roots have generally a great number of offsets about them, so that unless there is a want of them, the largest only should be chosen; which should be separated from all the smaller, and each planted in a separate pot, filled with kitchen-garden earth, and placed with other hardy exotic plants in the open air till autumn, when they must be removed into shelter for the winter season, during which time, they must not have too much wet, for that will rot the roots. This plant is so hardy as to live in the open air in mild winters, without any cover, if they are planted in warm borders, and have a dry soil; but with a little shelter in hard frost, they may be preserved in the full ground very well. It flowers in May, and the seeds ripen in August; but as the roots increase so plentifully, few persons care to sow the seeds, because the young plants will not flower in less than three years. The flowers of this plant have but little sweetness, altho' by Herman's title, it should have a very agreeable odour; but unless a person places it near him, it cannot be perceived. I have frequently received the seeds of this from the Cape of Good Hope, but have always found they produced the same sort.

The second sort grows naturally in moist or marshy grounds in many parts of Europe, so is rarely admitted into gardens.

The third sort grows naturally on the mountains near Aleppo. This hath a thick tuberous root, from which spring up several oval leaves, standing on pretty long foot-stalks; the spadix of the flower rises between the leaves, about six or eight inches high, supporting one white flower at the top.

The roots of this sort should be planted in pots filled with light earth, and in summer they may be placed with other exotic plants in the open air; but in winter they should be placed under a common hot-bed frame, to screen them from frost, to which if they are exposed the roots will be destroyed; there is little beauty in this plant, so it is only preserved in botanic gardens for variety.

CALLACARPA. See **JOHNSONIA**.

CALTHA. Lin. Gen. Plant. 623. *Marsh Marigold.*

The **CHARACTERS** are,

The flower hath no empalement, but is composed of five large, oval, concave petals, which spread open. It hath a great number of slender stamina, which are shorter than the petals, terminated by obtuse erect summits: in the center there are several oblong compressed germen situated, which have no styles, but are crowned by single stigma. The germen afterward become so many short pointed capsules, containing many roundish seeds.

This genus of plants is ranged in the seventh section of Linnæus's thirteenth class, intitled Polyandria Polygynia, the flowers of this class having many stamina, and of this section several germen.

The **SPECIES** are,

1. **CALTHA (Major)** foliis orbiculatis crenatis, flore majore. *Marsh Marigold with round crenated leaves, and a larger flower.* Populago flore majore. Tourn. Inst. 273.
2. **CALTHA (Minor)** foliis orbiculato-cordatis crenatis flore minore. *Marsh Marigold with round heart-shaped leaves which are crenated, and a smaller flower.*

These two sorts are supposed to be the same, but I have never observed either of them to vary, either in

their natural places of growth, or when they are removed into a garden. They both grow upon moist boggy land, in many parts of England, but the first is the most common; of this there is a variety with very double flowers, which for its beauty is preserved in many gardens. This is propagated by parting the roots in autumn, and should be planted in a moist soil and a shady situation; and as there are often such places in gardens, where few other plants will thrive, so these may be allowed to have room, and during their season of flowering, will afford an agreeable variety. This sort with double flowers, doth not appear so early in the spring as the single, but continues much longer in beauty. It flowers in May, and if the season is not very warm, will continue till the middle of June.

CALYCANTHUS. See **BASTERIA**.

CALYX [with botanists, signifies the cup of a flower before it opens: this is styled the empalement of the flower; in some plants this continues, and becomes afterward a cover to the seeds of herbs, and fruit of trees.] *Lat.* The cup inclosing or containing the flower.

CAMARA. See **LANTANA**.

CAMERARIA. Plum. Nov. Gen. 18. tab. 29. Lin. Gen. Plant. 264.

This plant was so named by father Plumier, in honour of Joachim Camerarius, a physician and botanist of Nuremberg; who published an edition of Matthioli, in Latin and High Dutch, with new figures of the plants, and many observations.

The **CHARACTERS** are,

The flower hath a short permanent empalement of one leaf, cut into five acute segments at the top: the flower is of one leaf, salver-shaped, having a long cylindrical tube at bottom, which is enlarged above, and divided at the top into five acute segments. It hath five short inflexed stamina, which are terminated by obtuse membranaceous summits. In the bottom of the tube are situated two roundish germen, having one common style, which is cylindrical, and the length of the stamina, crowned by two stigma; the under one is orbicular and flat, the other is concave. The germen afterward becomes two long, taper, leafy capsules, filled with oblong cylindrical seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flowers of this class having five stamina, and those in this section but one style.

The **SPECIES** are,

1. **CAMERARIA (Latifolia)** foliis ovatis, utrinque acutis transverse stratis. Hort. Cliff. 76. Lin. Sp. Plant. 210. *Cameraria with roundish leaves ending in points transversely ribbed.* Cameraria lato Myrti folio. Plum. Nov. Gen. 18.
 2. **CAMERARIA (Angustifolia)** foliis linearibus. Lin. Sp. Plant. 210. *Cameraria with long narrow leaves.* Cameraria angusto linariæ folio. Plum. Nov. Gen. 18.
- The first sort was sent me from the Havanna by the late Dr. Houstoun, where he found it growing naturally in great plenty. This rises with a shrubby stalk to the height of ten or twelve feet, dividing into several branches, garnished with roundish pointed leaves placed opposite, having many smooth transverse veins running from the midrib to the borders. The flowers are produced at the end of the branches in loose clusters, which have long tubes enlarging gradually upward, and at the top are cut into five segments, broad at their base, but end in sharp points: the flower is of a yellowish white colour. After the flowers are fallen, the germen become two leafy capsules joined at their base, and have two swelling protuberances on each side at the bottom, the middle being extended considerably longer; these have one cell, filled with cylindrical seeds. It flowers in August, but never produces any seeds in England.

The second sort hath an irregular shrubby stalk, which rises about eight feet high, sending out irregular branches, garnished with very narrow thin leaves placed opposite; these have two ribs running longitudinally

tudinally through each. The flowers are produced scatteringly at the end of the branches, which are shaped like those of the former sort, but smaller. Both these plants abound with an acrid milky juice like the Spurge. The second sort grows naturally in Jamaica.

These plants are propagated by seeds, which must be procured from the places of their growth, for they do not perfect their seeds in England. They may also be propagated by cuttings planted in a hot-bed during the summer months: they must have a bark-stove, for they are very tender plants; but in warm weather must have plenty of air.

CAMOCLADIA, the Maiden Plumb.

The CHARACTERS are,

It hath a tripartite coloured empalement of one leaf, spreading open; the flower hath three plain, oval, spreading petals, and three awl-shaped stamina shorter than the corolla, terminated by roundish incumbent summits, and an oval germen, but no style, crowned by an obtuse stigma; the empalement afterward becomes an oblong Plumb, having three punctures at the top, inclosing a nut of the same form.

This plant is ranged in the first order of Linnæus's third class, intitled Triandria Monogynia, the flower having three stamina and one style.

The SPECIES are,

1. CAMOCLADIA (*Integrifolia*) foliolis integris. Jacq. Amer. 12. *Camocladia with entire lobes*. Prunus racemosa, caudice non ramosa, alato fraxini folio non crenato, fructu rubro subdulci. Sloan. Cat. 184. *The Maiden Plumb*.

2. CAMOCLADIA (*Dentata*) foliolis spinoso-dentatis. Jacq. Amer. 12. *Camocladia with prickly indented leaves*.

The first sort grows naturally in Jamaica, and also in many other of the islands in the West Indies; this rises with an upright stem near twenty feet high, garnished with long winged leaves, whose pinnæ are entire; at the top there are a few branches sent out about a foot long, which sustain the flowers and fruit.

The second sort grows naturally at the Havanna, where it rises about the same height with the former; but as the flowers and fruit of this are unknown to the author, he can give no farther account of them.

These plants are propagated by seeds, when they can be obtained from the places of their growth, which should be sown in pots and plunged into a hot-bed; the plants, when fit to remove, should be each planted in a small pot, and plunged into a tan-bed, and in the autumn should be plunged into the bark-bed in the stove, and treated as other tender plants.

CAMPANIFORM flowers [of campana, a bell; and forma, Lat. shape,] such flowers as in shape resemble a bell.

CAMPANULA. Tourn. Inst. R. H. 108. tab. 38. Lin. Gen. Plant. 201. [signifies a little bell, as tho' parva campana, Lat. so called, because the flowers resemble a little bell.]

The CHARACTERS are,

The empalement is divided into five acute parts, is upright, spreading, and rests upon the germen. The flower is of one leaf, shaped like a bell, spreading at the base where there are holes. In the bottom is situated the five cornered nektarium, which is joined to the top of the receptacle. It hath five short stamina, which are inserted in the top of the valves of the nektarium, terminated by long compressed summits: below the receptacle is situated the angular germen, supporting a style which is longer than the stamina, crowned by a thick, oblong, tripartite stigma. The empalement afterward becomes a roundish angular capsule, which in some species have three, and in others five cells, each having a hole toward the top, through which the seeds are scattered when ripe.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia; the flowers of this class have five stamina, and in this section but one style.

The SPECIES are,

1. CAMPANULA (*Pyramidalis*) foliis ovatis glabris subserratis, caule erecto paniculato, ramulis brevibus. Lin. Sp. 233. *Bell-flower with oval smooth leaves sawed below, an upright paniculated stalk, and short branches*. Campanula pyramidata altissima. Tourn. Inst. 109. *Tallest pyramidal Bell-flower*.
2. CAMPANULA (*Decurrens*) foliis radicalibus obovatis, caulinis lanceolato-linearibus subserratis sessilibus remotis. Lin. Sp. Plant. 164. *Bell-flower with lower leaves oval, and those on the stalks narrow, spear-shaped, sawed, and growing close to the stalks at remote distances*. Campanula perficæ folio. Clus. Hist. 171. *Peach-leaved Bell-flower*.
3. CAMPANULA (*Medium*) capsulis quinquelocularibus testis, calycis sinibus reflexis. Vir. Cliff. 16. *Bell-flower with a covered capsule, having five cells, and the borders of the cup reflexed*. Campanula horrensis folio & flore oblongo. C. B. P. 94. *Commonly called Canterbury Bell-flower*.
4. CAMPANULA (*Trachelium*) caule angulato, foliis petiolatis, calycibus ciliatis, pedunculis trifidis. Vir. Cliff. 16. *Bell-flower with an angular stalk, leaves having foot-stalks, a hairy empalement, and trifid foot-stalks to the flowers*. Campanula vulgarior, foliis urticæ vel major & asperior. C. B. P. 94. *Nettle-leaved Bell-flower*.
5. CAMPANULA (*Latifolia*) foliis ovato-lanceolatis, caule simplicissimo tereti, floribus solitariis pedunculatis fructibus cernuis. Vir. Cliff. 17. *Bell-flower with oval spear-shaped leaves, a single taper stalk, flowers growing singly upon foot-stalks, and pendent fruit*. Campanula maxima foliis latissimis. C. B. P. 94. *Greatest Bell-flower with broadest leaves*.
6. CAMPANULA (*Rapunculus*) foliis undulatis radicalibus lanceolato-ovalibus, paniculâ coarctatâ. Hort. Upsal. 40. *Bell-flower with waved leaves, those growing near the stalk oval and spear-shaped, and a compressed panicle*. Campanula radice esculentâ. H. L. *Commonly called Rampion*.
7. CAMPANULA (*Glomerata*) caule angulato simplici, floribus sessilibus capitulo terminali. Vir. Cliff. 16. *Bell-flower with a single angular stalk, flowers growing close, and terminating in a head*. Campanula pratensis flore conglomerato. C. B. P. 94. *Meadow Bell-flower with flowers gathered in bunches*.
8. CAMPANULA (*Speculum*) caule ramosissimo diffuso foliis oblongis subcrenatis, calycibus solitariis corollâ longioribus, capsulis prismaticis. Hort. Upsal. 41. *Bell-flower with a very branching diffused stalk, oblong crenated leaves, solitary flower-cups which are longer than the petal, and prismatic capsules*. Campanula arvensis erecta Euphrasie luteæ, seu Trifraginis appulæ foliis. H. Cath. *Commonly called upright Venus Looking-glass*.
9. CAMPANULA (*Hybrida*) caule basi subramoso stricto, foliis oblongis crenatis, calycibus aggregatis corollâ longioribus, capsulis prismaticis. Lin. Sp. Plant. 168. *Bell-flower with a stalk branching at the bottom, oblong crenated leaves, flower-cups gathered together, which are longer than the petal, and prismatic capsules*. Campanula arvensis minima erecta. Mor. Hist. 2. 457. *Small Venus Looking-glass*.
10. CAMPANULA (*Erinus*) caule dichotomo, foliis sessilibus utrinque dentatis. Hort. Cliff. 65. *Bell-flower with a forked stalk, and leaves growing close to the stalks, which are indented on both sides*. Campanula minor annua, foliis incis. Mor. Hist. 1. 458. *Smaller annual Bell-flower with cut leaves*.
11. CAMPANULA (*Pentagonia*) caule subdiviso ramosissimo, foliis linearibus acuminatis. Hort. Cliff. 66. *Bell-flower with a very branching divided stalk, and narrow pointed leaves*. Campanula pentagonia flore amplissimo Thracia. Tourn. Inst. 112. *Five-cornered Bell-flower of Thracia*.
12. CAMPANULA (*Perfoliata*) caule simplici, foliis cordatis dentatis amplexicaulibus, floribus sessilibus aggregatis. Hort. Upsal. 40. *Bell-flower with a single stalk, heart-shaped indented leaves which embrace the stalk, and flowers gathered together, growing close to the stalk*.

- Campanula pentagonia perfoliata*. Mor. Hist. 2. p. 457. *Five-cornered perfoliate Bell-flower*.
13. *CAMPANULA (Americana)* caule ramoso, foliis linguiformibus crenulatis margine cartilagineo. Prod. Leyd. 246. *Bell-flower with a branching stalk, and tongue-shaped crenulated leaves with stiff edges*. *Campanula minor Americana*, foliis rigidis flore cæruleo patulo. H. L. 107. *Smaller American Bell-flower*.
14. *CAMPANULA (Canariensis)* foliis hastatis dentatis oppositis petiolatis, capsulis quinquelocularibus. Lin. Sp. Plant. 168. *Bell-flower with spear-shaped indented leaves growing opposite, having foot-stalks and capsules with five cells*. *Campanula Canariensis*, atriplicis folio, tuberosâ radice. *Canary Bell-flower*.
15. *CAMPANULA (Patula)* foliis strictis, radicalibus lanceolato-ovalibus, panicula patula. Flor. Suec. 186. *Bell-flower whose radical leaves are oval, spear-shaped, and spreading flowers in panicles*. *Campanula eiculenti* facie, ramis & floribus patulis. Hort. Elth. 1. 68.
16. *CAMPANULA (Cervicaria)* hispida, floribus sessilibus, capitulo terminali, foliis lanceolato-linearibus undulatis. Lin. Sp. 235. *Rough Bell-flower with sessile flowers terminating the stalks, and linear, spear-shaped, waved leaves*. *Campanula foliis echii*. C. B. 36.
17. *CAMPANULA (Saxatilis)* foliis obovatis crenatis, floribus alternis nutantibus, capsulis quinquecarinatis. Lin. Sp. 237. *Bell-flower with oval crenated leaves, nodding flowers placed alternate, and boat-shaped capsules with five cells*. *Campanula Cretica saxatilis*, bellidis folio, magno flore. Tourn. Inst. 111.

There are several other species of this genus, some of which grow naturally in England, and others in the northern parts of Europe, which have but little beauty, therefore are seldom cultivated in gardens, so I shall not enumerate them here. There are also several varieties of some of the sorts here mentioned, which I shall take notice of in their proper place; but as they are not distinct species, they are omitted in the above list.

The first sort hath thick tuberous roots which are milky; this sends out three or four strong, smooth, upright stalks, which rise near four feet high, and are garnished with smooth oblong leaves, whose edges are a little indented. The lower leaves are much broader than those which adorn the stalks. The flowers are produced from the side of the stalks, and are regularly set on for more than half their length, forming a sort of pyramid; these are large, open, and shaped like a bell. The most common colour of the flowers is a light blue; but there have been some with white flowers, which make a variety when intermixed with the blue, but the latter is most esteemed.

This plant is cultivated to adorn halls, and to place before the chimnies in the summer, when it is in flower, for which purpose there is no plant more proper; for when the roots are strong, they will send out four or five stalks, which will rise as many feet high, and are garnished with flowers great part of their length. These upright stalks send out some short side branches, which are also adorned with flowers, so that by spreading the upright stalks to a flat frame composed of slender laths (as is usually practised) the whole plant is formed into the shape of a fan, and will spread near the width of a common fire-place. When the flowers begin to open, the pots are removed into the rooms, where, being shaded from the sun, and kept from the rain, the flowers will continue long in beauty; and if the pots are every night removed into a more airy situation, but not exposed to heavy rains, the flowers will be fairer, and continue much longer in beauty.

Those plants which are thus treated, are seldom fit for the purpose the following season, therefore a supply of young plants should be annually raised. The common method of propagating this plant, is by dividing the roots. The best time for doing this is in September, that the offsets may have time to get strong roots before winter.

This method of propagating by the offsets is the

quickest, therefore generally practised, but the plants which are raised from seeds, are always stronger; the stalks will rise higher, and produce a greater number of flowers, therefore I recommend it to the practice of the curious; but in order to obtain good seeds, there should be some strong plants placed in a warm situation, near a pale, or wall, in autumn; and, if the following winter should prove severe, they should be covered either with hand-glasses or mats, to prevent their being injured by the frost; and, in the summer, when the flowers are fully open, if the season should prove very wet, the flowers must be screened from great rains, otherwise there will be no good seeds produced: the not observing this, has occasioned many to believe that the plants do not bear seeds in England, which is a great mistake, for I have raised great numbers of the plants from seeds of my own saving; but I have always found that the plants which have been long propagated by offsets, seldom produce seeds, which is the same with many other plants which are propagated by slips, or cuttings, which in a few years become barren.

When the seeds are obtained, they must be sown in autumn in pots, or boxes, filled with light undunged earth, and placed in the open air till the frost or hard rains come on, when they should be placed under a hot-bed frame, where they may be sheltered from both, but in mild weather the glasses should be drawn off every day, that they may enjoy the free air; with this management the plants will come up early in the spring, and then they must be removed out of the frame, placing them first in a warm situation; but when the season becomes warm, they should be removed where they may have the morning sun only. During the following summer they must be kept clean from weeds, and in very dry weather, now and then refreshed with water, which must be given with great caution, for the roots are very subject to rot with too much moisture. In September the leaves of the plants will begin to decay, at which time they should be transplanted; therefore there must be one or two beds prepared, in proportion to the number of plants. These beds must be in a warm situation, and the earth light, sandy, and without any mixture of dung, which last is an enemy to this plant. If the situation of the place is low, or the natural soil moist, the beds must be raised five or six inches above the surface of the ground, and the natural soil removed a foot and a half deep, putting lime rubbish eight or nine inches thick in the bottom of the trench, to drain off the moisture. When the beds are prepared, the plants must be taken out of the pots, or cases, very carefully, so as not to break or bruise their roots, for they are very tender, and, on being broken, the milky juice will flow out plentifully, which will greatly weaken them. These should be planted at about four inches distance each way, with the head or crown of the root half an inch below the surface; if there happens a gentle shower of rain soon after they are planted, it will be of great service to the plants; but as the season sometimes proves very dry at this time of the year, in that case, it will be proper to give them a gentle watering three or four days after they are planted, and to cover the beds with mats every day, to prevent the sun from drying the earth; but these must be taken off in the evening, that the dew may fall on the ground. Towards the end of October the beds should be covered over with some old tanners bark to keep out the frost, and where there is not convenience of covering them with frames, they should be arched over with hoops, that in severe frosts they may be covered with mats; for these plants, when young, are often destroyed in winter, where this care is wanting. In the spring the coverings must be removed, and the following summer the plants must be kept clean from weeds; and, if the season should prove very dry, they must now and then be refreshed with water. The following autumn the surface of the ground should be stirred between the plants, and

some

some fresh earth spread over the beds, and in the winter covered as before. In these beds the plants may remain two years, during which time they must be treated in the manner before directed; by which time the roots will be strong enough to flower: in September they should be carefully taken up, and some of the most promising planted in pots; the others may be planted into warm borders, or in a fresh bed, at a greater distance than before, to allow them room to grow. These plants which are potted should be sheltered in winter from great rains and hard frosts, otherwise they will be in danger of rotting, or at least be so weakened, as not to flower with any strength the following summer; and those which are planted in the full ground, should have some old tanners bark laid round them, to prevent the frost from entering deep to the roots; with this management these plants may be brought to the utmost perfection, and a constant succession of good roots raised, which will be much preferable to those which are propagated by offsets. I have been informed that there is a double flower of this kind, but as I have not seen any, I can give no farther account of it. This sort is by some called Steeple Bell-flower.

The second sort grows naturally in the northern parts of Europe, but has been long cultivated in the English gardens; of this there are the following varieties, viz. the single, blue, and white flower, which have been long here; and the double flower of both colours, which has not been more than twenty-eight years in England, but has been propagated in such plenty, as to have almost banished those with single flowers from the gardens. All these varieties are easily propagated by parting their roots in autumn, every head which is then slipped off will take root; they are extreme hardy, so will thrive in any soil or situation, therefore are very proper furniture for the common borders of the flower-garden.

This hath a root composed of many fibres, and sends up an angular, or channelled stiff stalk, about two feet and a half high, garnished with oblong, oval, stiff leaves near the root, which are placed without order; but those on the stalks are longer and narrower, having their edges slightly indented, and are of a shining green. The flowers are produced towards the upper part of the stalk upon short foot-stalks. These are shaped like those of the former sort, but are smaller, and more expanded. This flowers in June and July, and in cool seasons there will be some continue great part of August.

The third sort is a biennial plant, which perishes soon after it hath ripened seeds. It grows naturally in the woods of Italy and Austria, but is cultivated in the English gardens for the beauty of its flowers. Of this sort there are the following varieties, the blue, the purple, the white, the striped, and the double flowering, but the last two are not very common in England.

This hath oblong, rough, hairy leaves, which are serrated on their edges, coming out without order from the root; from the center of these a stiff, hairy, furrowed stalk, arises about two feet high, sending out several lateral branches, from the bottom upward, garnished with long, narrow, hairy leaves, sawed on their edges, and are placed alternately; from the setting on of these leaves, come out the foot-stalks of the flower, those which are on the lower part of the stalk and branches being four or five inches long, diminishing gradually in their length upward, and thereby form a sort of pyramid. The flowers of this kind are very large, so make a fine appearance; they come out the beginning of June, and, if the season is not very hot, will continue a month in beauty. The seeds ripen in September, and the plants decay soon after.

It is propagated by seeds, which must be sown in the spring on an open bed of common earth, and when the plants are fit to remove, they should be transplanted into the flower-nursery, in beds six inches asunder, observing to water them frequently till they

have taken new root; after which they will require no other culture, but to keep them clean from weeds till the following autumn, when they should be transplanted into the borders of the flower-garden. As these plants decay the second year, there should be annually young ones raised to succeed them.

The fourth sort hath a perennial root, which sends up several stiff hairy stalks, having two ribs or angles. These put out a few short side branches, garnished with oblong, pointed, hairy leaves, deeply sawed on their edges. Toward the upper part of the stalks the flowers come out alternately, upon short trifid foot-stalks, having hairy empalements. The flowers are of the shape of the former, but shorter, spread more at the brim, and are pretty deeply cut into many acute segments. This flowers in June, and the seeds ripen in autumn.

The varieties of this are, the deep and pale blue; the white with single flowers, and the same colours with double flowers. The double sorts are propagated by parting their roots in autumn, which should be annually performed, otherwise the flowers are apt to degenerate to single; to prevent which, the roots should be every autumn transplanted and parted. The soil should not be too light or rich, in which they are planted, for in either of these they will degenerate; but in a strong fresh loam their flowers will be in the greatest perfection. These plants are extreme hardy, so may be planted in any situation; those with single flowers do not merit a place in gardens.

The fifth sort grows naturally in the northern parts of England: this hath a perennial root, composed of many fleshy fibres, which abound with a milky juice, from which arise several strong, round, single stalks, which never put out branches, but are garnished with oval spear-shaped leaves, slightly indented on their edges, which are placed alternately. Toward the upper part of the stalk the flowers come out singly upon short foot-stalks; these spread open at the brim, where they are deeply cut into five acute segments. After the flowers are past, the empalement becomes a five-cornered seed-vessel, which turns downward till the seeds are ripe, when it rises upward again.

The varieties of this are, the blue, purple, and white flowering. This sort is easily propagated by seeds, which it furnishes in great plenty, and, if suffered to scatter, the plants will come up in as great plenty the following spring; when they may be transplanted into the nursery till autumn, at which time they should be transplanted where they are designed to remain. As this sort delights in shade, the plants may be planted under trees, or in shady borders where few better things will thrive, they will afford an agreeable variety when they are in flower. It flowers in June and July, and the seeds ripen in autumn.

The sixth sort hath roundish fleshy roots which are eatable, and are much cultivated in France for sallads, and some years past it was cultivated in the English gardens for the same purpose, but is now generally neglected. It grows naturally in several parts of England, but the roots never grow to half the size of those which are cultivated. This is propagated by seeds, which should be sown in a shady border the latter end of May, and when the plants are about an inch high, the ground should be hoed, as is practised for Onions, to cut up the weeds, and thin the plants to the distance of three or four inches; and when the weeds come up again, they must be hoed over to destroy them: this, if well performed in dry weather, will make the ground clean for a considerable time, so that being three times repeated, it will keep the plants clean till winter, which is the season for eating the roots, when they may be taken up for use as they are wanted. These will continue good till April, at which time they will send out their stalks, when they will become hard and unfit for use, as do also those roots which have flowered; so that the young roots only are such which are fit for the table, therefore when the seeds are sown too early, the plants frequently run up to flower the same year, which spoils their roots.

This

This sort sends out upright stalks about two feet high, which are garnished with oblong spear-shaped leaves, placed alternately. Towards the upper part of the stalk the small Bell-flowers are produced, standing upright close to the stalk; some of these flowers are blue, and others white; they come out in June and July, and the seeds ripen in autumn.

The seventh sort grows naturally upon chalky pastures in many parts of England, where the stalks do not rise many times a foot high, and in other places it grows to double that height, which has occasioned their being taken for two distinct plants. This hath a perennial root, which sends up several round hairy stalks, which often rise upward of two feet high; the bottom leaves are broad, and stand upon long foot-stalks, and are slightly sawed on their edges. Those which are upon the stalks are long, narrow, have no foot-stalks, and are placed alternately at considerable distances. From the wings of the leaves, towards the upper part of the stalk, come out long naked foot-stalks, supporting two or three bell-shaped flowers, closely joined together in a head, and the main stalk is terminated by a large cluster of the same flowers, which are succeeded by roundish capsules filled with small seeds. This plant is easily propagated either by seeds, or parting their roots, and will thrive in any soil or situation. It flowers in July, and the seeds ripen in autumn.

The eighth sort is an annual plant, which rises with slender stalks a foot high, branching out, garnished with oblong leaves, a little curled on their edges; from the wings of the leaves come out the flowers, sitting close to the stalks, which are of a beautiful purple, inclining to a Violet-colour, divided into five segments, which resemble so many leaves, and in the evening contract and fold into a pentagonal figure; from whence it is by some titled *Viola Pentagonia*, or five-cornered Violet. The empalement which encompasses the flower, is composed of five, long, narrow, green leaves, which spread open, and are much longer than the petals of the flower; these remain on the top of the prismatic seed-vessel, which is filled with small angular seeds. If this plant is sown in autumn, it will grow much taller, and flower a month earlier than when the seeds are sown in the spring. The autumnal plants will flower in May, and the spring plants in June and July. There is a variety of this with white flowers, and another with pale purple.

The ninth sort is the common *Venus Looking-glass*, which hath been long cultivated in the English gardens. This sort seldom rises more than six inches high, with a stalk branching from the bottom upward, garnished with oval leaves, sitting close to the stalks, from the base of which the branches are produced, which are terminated by flowers very like those of the former sort.

The tenth sort grows naturally in the south of France and Italy. This is also a low annual plant, which seldom rises six inches high, but divides into many branches, garnished with short oval leaves, sitting close, which are deeply indented on both sides. The flowers are produced at the ends of the branches, which are shaped like those of the other sort last mentioned, but they are small, their colours less beautiful, and the leaves of the empalement are broader.

The eleventh sort grows naturally in Thrace, but hath been long in the English gardens. This is also a low annual plant, which rises little more than six inches high; the stalks divide by pairs, and frequently there arises a branch from the middle of the divisions; the lower leaves are oblong and obtuse, but those which come out toward the end of the branches are much narrower, and pointed. The flowers come out single at the end of the branches, having a long five-leaved empalement, and are larger than those of the three last sorts, of a fine blue colour; the seeds are like those of the eighth sort.

The twelfth sort is an annual plant, which, in good ground, will rise a foot and a half high, but in poor

land, or it where it grows wild among corn, scarcely rises to the height of six inches. The stalk is single, rarely putting out any branches, unless near the root, from whence there are sometimes one or two short lateral branches produced. The leaves are roundish, and embrace the stalk at their base; their edges are sharply sawed, and from their base comes out a close tuft of flowers, surrounded by the leaf, as in an empalement. The flowers are five-cornered, shaped like those of the *Venus Looking-glass*, but are much smaller; these are produced the whole length of the stalk. The seeds are inclosed in short capsules, which are shaped like those of the former sorts. It grows in Italy, and also in Virginia. If the seeds of this sort are permitted to scatter, the plants will come up without care; or the seeds may be sown in the spring, in the same manner as those of the last sorts, and treated in the same way.

The thirteenth sort is a native of America, but has been long cultivated in the gardens of the curious, both in England and Holland. This hath many rigid oblong leaves coming out from the root on every side, which form a sort of head like those of *House-leek*, crenated, having a strong rib running on their border longitudinally. From the center of the plant proceeds the stalk, which rises about a foot high, and is thinly garnished with very narrow stiff leaves, of a shining green. From the wings of the leaves come out the foot-stalks of the flower, which are from two to four inches long, each being terminated by one spreading bell-shaped flower, whose empalement is short, and cut into five acute segments. The style of this is longer than the petal, and is crowned by a bifid stigma. There is a white and a blue flower of this sort in the gardens, but in Holland they have it with a double flower. This sort doth not produce seeds in England, so is only propagated by offsets; these may be taken off from the old plants in August, that they may get good root before the cold weather begins: they must be planted in small pots filled with fresh, light, loamy earth, and placed in the shade until they have taken root; then they may be placed with other hardy exotic plants, and in autumn they must be removed into shelter, for in severe winters these plants are often destroyed which are exposed; though in mild winters they will live in the open air. It flowers in July and August.

The fourteenth sort is a native of the Canary Islands, from whence it was introduced to the gardens in Europe, where it hath been many years cultivated; and of late years great numbers of the plants have been raised from seeds which were brought from thence, but the flowers of these new-raised plants are not so well coloured as those of the old ones.

This hath a thick fleshy root, which is of an irregular form, sometimes running downward like a *Parinsep*, at other times dividing into several knobs near the top, and when any part of the root is broken, there issues out a milky juice at the wound. There are many strong fleshy fibres sent out, which strike deep into the ground, and from these a numerous quantity of small ones. From the head, or crown of the root, arise one, two, three, or more stalks, in proportion to the size of the root; but that in the center is generally larger, and rises higher than the others. These stalks are very tender, round, and of a pale green; their joints are far distant from each other, and when the roots are strong, the stalks will rise ten feet high, sending out several smaller side branches. At each joint they are garnished with two, three, or four spear-shaped leaves, with a sharp pointed beard on each side. These are of a sea-green, and, when they first come out, are covered slightly with an Ash-coloured pounce. From the joints of the stalk the flowers are produced, which are of the perfect bell-shape, and hang downward; they are of a flame colour, marked with stripes of a brownish red; the flower is divided into five parts, at the bottom of each is situated a nectarium, covered with a white transparent skin, much resembling those of the *Crown Imperial*, but are

C A M

are smaller; upon each of these is situated a stamen, which rises almost the length of the petal, and is terminated by oblong summits. In the center of the flower is situated the style, which is longer than the stamina, and is crowned by a trifid stigma, which is reflexed. The flowers begin to open in the beginning of October, and there is often a succession of them till March. The stalks decay to the root in June, and new ones spring up in August.

It is propagated by parting their roots, which must be done with caution; for if the roots are broken or wounded, the milky juice will flow out plentifully, so that if these are planted before the wounds are skinned over, it occasions their rotting; therefore whenever any of them are broken, they should be laid in the green-house a few days to heal. These roots must not be too often parted, especially if they are expected to flower well; for by frequent parting the roots are weakened. The best time for transplanting and parting their roots, is in July, soon after the stalks are decayed. The earth in which these should be planted, should not be rich, for that will cause them to be luxuriant in branches, and but thinly garnished with flowers. The soil in which they have succeeded best, is a light sandy loam, mixed with a fourth part of screened lime-rubbish: when the roots are first planted, the pots should be placed in the shade; and, unless the season is very dry, should not be watered, for during the time they are inactive, wet is very injurious to them. About the middle of August the roots will begin to put out fibres, at which time, if the pots are placed under a hot-bed frame, and as the nights grew cool, covered with the glasses, but opened every day to enjoy the free air, it will greatly forward them for flowering, and increase their strength; when the stalks appear, the plants must be now and then refreshed with water, which must not be given too often, nor in great quantity. The plants thus managed, by the middle of September, will have grown so tall, as not to be kept longer under the frame, so they should be removed into a dry airy glass-case, where they may enjoy the free air in mild weather, but screened from cold. During the winter season they must be frequently refreshed with water, and guarded from frost; and in spring, when the stalks begin to decay, the pots should be set abroad in the shade, and not watered.

The fifteenth sort grows naturally in some of the north-west counties of England. It is a biennial plant, very like the eatable sort, but the branches grow more horizontal, and the flowers spread wider open.

This is propagated by seeds, which should be sown in the autumn; for those seeds which are sown in the spring often fail, or at least lie a year in the ground before they grow. When the plants come up, they should be thinned and kept clean from weeds, which is all the culture they require.

The sixteenth sort grows naturally in Germany and Sweden; this hath rough leaves: the stalk rises two feet high, garnished with narrow spear-shaped leaves, and are terminated by an obtuse spike of flowers.

The seventeenth sort grows naturally in Crete, upon rocks, where the roots penetrate the fissures, whereby the plants continue much longer than when they are transplanted into gardens. The stalks of this rise a foot high, garnished with oval crenated leaves; the flowers are large, blue, and placed alternate, nodding toward the ground; these open in July, and are succeeded by seed-vessels, having five cells filled with small seeds.

These plants are propagated by seeds, which, if sown in the autumn, will more certainly succeed than when sown in the spring. When the plants are fit to remove, they should be transplanted into beds, and treated in the same manner as the hardy sorts before-mentioned; but a few plants of the last sort may be planted in pots, to be sheltered in winter.

CAMPHORA. See LAURUS.

CAMPHOROSMA. Camphorata. Tourn. Inst.

C A N

The CHARACTERS are,

It hath a pitcher-shaped four-pointed empalement, which is permanent, but no corolla. It has four slender stamina which are equal, terminated by oval summits, and an oval compressed germen, supporting a slender style longer than the empalement, crowned by acute stigma. The empalement afterward becomes a capsule crowned with one cell open at the top, inclosing one compressed seed.

The SPECIES are,

1. CAMPHORASMA (*Monspeliaca*) foliis hirsutis linearibus. Amoen. Acad. 1. p. 392. *Camphorata with linear hairy leaves.* Camphorata hirsuta. C. B. P. 486.
2. CAMPHORATA (*Glabra*) foliis subtriquetris glabris inermibus. Amoen. Acad. p. 393. *Camphorata with smooth three-cornered leaves.*

The first sort grows naturally about Montpellier. It is an annual plant, whose branches trail on the ground, and extend each way a foot and more in length, garnished with linear hairy leaves placed close on the branches; the flowers are produced from the joints of the stalks, which are so small as to be scarce perceptible, having no petals but a pitcher-shaped empalement, which afterward becomes a capsule to the seed. This is an annual plant, which is propagated by seeds, which, if sown in the autumn, will more probably succeed, than if sown in the spring; and if the seeds are permitted to fall in the autumn, there will be a supply of young plants the following spring.

The second sort grows naturally in the Helvetian mountains. This is a perennial plant, whose branches trail on the ground; the leaves are smooth, three-cornered, and unarmed. The flowers are not more visible than those of the first sort, and the empalement becomes a cover to the seeds.

These plants are preserved in some gardens, more for the sake of variety, than for either beauty or use; if the seeds are sown in any abject part of the garden, and when the plants come up, they are thinned, and afterward kept clean from weeds, they will ripen their seeds, which, if permitted to scatter, there will be a supply of plants.

CAMPION. See LYCHNIS.

CANDLE-BERRY-TREE. See MYRICA.

CANDY-TUFT. See IBERIS.

CANNA. Lin. Gen. Plant. 1. Indian flowering Reed. In French Balisier.

The CHARACTERS are,

The flower hath a three-leaved empalement, which is permanent, erect, and coloured. It hath one petal, which is divided into six parts: the three upper segments are erect, and broader than the lower, which are longer, two of which are erect, and the other turns back and is twisted. It hath one spear-shaped stamina rising as high as the petal, having the appearance of a segment, which hath a slender summit sitting upon its border. Below the empalement is situated a roundish rough germen, supporting a flat style, with a slender stigma fastened to its border. After the flower is past, the germen becomes an oblong, roundish, membranaceous capsule, having three longitudinal furrows, crowned by the empalement, which hath three cells filled with round smooth seeds.

This genus of plants is ranged in the first section of Linnaeus's first class, intitled Monandria Monogynia. The flowers of this class have but one stamen, and in this section but one style.

The SPECIES are,

1. CANNA (*Indica*) foliis ovatis utrinque acuminatis nervosis. Prod. Leyd. 11. *Canna with oval nervous leaves pointed at both ends.* Cannacorus latifolius vulgaris. Tourn. Inst. 367.
2. CANNA (*Latifolia*) foliis oblongo-ovato, acuminatis, segmentis florum angustioribus. *Canna with oblong, oval, pointed leaves, and the segments of the flower narrow.* Cannacorus amplissimo folio flore rutilo. Tourn. Inst. 367.
3. CANNA (*Coccinea*) foliis ovatis obtusis nervosis, spicis florum longioribus. *Canna with oval, obtuse, nervous leaves, and longer spikes of flowers.* Cannacorus flore Coccineo splendente. Tourn. Inst. 367.

4. *CANNA (Lutea)* foliis ovatis petiolatis nervosis spatha floribus longiore. *Canna with oval, obtuse, nervous leaves, having foot-stalks, and a longer hood to the flower.* Cannacorus flore luteo punctato. Tourn. Inst. R. H. 367.

5. *CANNA (Glauca)* foliis lanceolatis petiolatis enervi-bus. Prod. Leyd. 11. *Canna with spear-shaped smooth leaves having foot-stalks.* Cannacorus glaucophyllus, ampliore flore, Iridis palustris facie. Hort. Elth. 69. The first sort grows naturally in both Indies: the inhabitants of the British islands in America, call all the species without distinction Indian Shot, from the roundness and hardness of the seeds.

This plant hath a thick, fleshy, tuberous root, which divides into many irregular knobs, spreading wide near the surface of the ground, sending out many large oval leaves without any order; these, at their first appearance, are twisted like a horn, but afterwards expand and are near a foot long, and five inches broad in the middle, lessening gradually to both ends, and terminating in points. They have many large transverse veins running from the midrib to the sides, which are prominent on their under side; and between each of these run two smaller, parallel, pointed veins, which are peculiar to this species. The stalks are herbaceous, rising four feet high, encompassed by the broad leafy foot-stalks of the leaves; these are compressed on two sides; at the upper part of the stalk the flowers are produced in loose spikes, each being at first covered by a leafy hood, which afterward stands below the flower, and turns to a brown colour. Each flower hath one petal, which is cut almost to the bottom into six slender segments, the three upper being broadest; these are of a pale red colour. The flower is encompassed by a three-leaved empalement, which sits upon a small, roundish, rough germen, which, after the flower is fallen, swells to a large fruit or capsule oblong and rough; having three longitudinal furrows, and is crowned by the three-leaved empalement of the flower which remains. When the fruit is ripe, the capsule opens lengthways into three cells, which are filled with round, hard, black, shining seeds. The principal season of these plants flowering, is in June, July, and August.

As this sort is a native of the warmest parts of America, it requires to be placed in a moderate stove in winter, otherwise the roots will decay. I have frequently tried to keep these roots through the winter in a green-house, but could not succeed; for although some have escaped, yet they were so much weakened by the cold, as not to recover their strength the following summer, so as to flower in any tolerable degree of perfection; so that I have since constantly kept them in winter in a moderate stove, where they always flower in that season, at which time they make a fine appearance; and in the summer, place them abroad in a sheltered situation with other tender exotic plants, where they flower again, and produce ripe seeds annually.

The second sort grows naturally in Carolina, and some of the other northern provinces of America. The leaves of this sort are longer than those of the former, and terminate in sharper points. The stalks grow taller, and the segments of the flower are much narrower; the colour is a pale red, so it makes no great appearance. The seeds are like those of the former sort. If the roots of this sort are planted in warm borders and a dry soil, they will live through the winter in the open air. I have plants of this sort in the Chelsea garden, which have survived twelve winters in a south-west border without cover, and flower well every year, but do not produce seeds.

The third sort hath larger leaves than either of the former; the stalks rise much taller. I have received the seeds of this from America, and from the Brazils; by the title of Wild Plantain. The flower-stalks of this sort rise more than six feet high. The leaves are very large, and those near the root have long foot-stalks. The flowers are produced in larger spikes than those of the former sort, and are of a

much brighter scarlet. The seed-vessels are longer, and the seeds larger than those; and these differences are permanent from seeds, so that I make no doubt of its being a distinct species.

The fourth sort is less common in America than either of the former. I received the seeds of this from India, but have had two varieties arise from the seeds, one with a plain yellow, and the other a spotted flower, which I find are apt to change from one to the other, when propagated by seeds. This sort hath shorter and rounder leaves than either of the former sorts. The stalks seldom rise higher than three feet, and the spikes of flowers are like those of the first species, excepting the colour of the flowers.

The seeds of the fifth sort I received from Carthage in New Spain, in the year 1733, which produced very strong plants the first year, some of which flowered the same autumn. The roots of this are much larger than either of the former sorts, and strike down strong fleshy fibres deep in the ground. The stalks rise seven or eight feet high. The leaves are near two feet long, narrow, smooth, and of a sea-green colour. The flowers are produced in short thick spikes at the extremity, which are large, and of a pale yellow colour; the segments of the petal are broad, but their shape like those of the other sorts. The seed-vessels are larger, and much longer than those of the other sorts, but contain fewer seeds, which are very large. The young plants which are raised from seeds of this sort, do more certainly flower than the old roots, or the offsets taken from them; for the roots send out many offsets, which will spread to a considerable distance where they have room, but seldom produce flowers; so that it is the best way to raise a succession of plants from seeds, and to throw out the old ones after they have perfected their seeds.

All the sorts are propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted into separate small pots, filled with rich kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, observing to shade them till they have taken root; after which, they should have a large share of free air admitted to them every day in warm weather, and be frequently refreshed with water. As these plants will make great progress in their growth, they must be shifted into larger pots filled with the same sort of earth, and part of them plunged into the hot-bed again; and the others may be placed abroad in June, with other exotic plants, in a warm situation. Those which are placed in the hot-bed, will be strong enough to flower well in the stove the following winter; but those in the open air, will not flower before the following summer. These may remain abroad till the beginning of October, when they must be removed into the stove, and treated in the same manner as the old plants; and in May, if a gentle hot-bed is made, and covered a foot thick with rich earth, and the plants turned out of the pots, planting them with their balls of earth upon the hot-bed, covering each with a bell-glass, which may be raised on one side every day to admit air to the plants; and as these advance, they must be gradually inured to bear the open air. With this management the plants will grow much taller, and flower stronger than those which are kept in pots, and from these good seeds may be expected in autumn. These plants will continue many years with proper management; but as young plants always flower better than the old roots, it is scarce worth while to continue them after they have borne good seeds.

The second sort, which is much hardier than either of the other, should have a different treatment. The young plants of this must be earlier inured to the open air, where they may remain till the frost begins; then they must be placed in the green-house, and should have but little wet in winter; and the beginning of May, these should be turned out of the pots, and planted in a warm south border, in a dry soil, where they will thrive and produce flowers annually;

but

but as there is little beauty in this sort, a few plants for variety will be as many as most persons will choose to keep. There is a variety of this with variegated leaves, which is preserved in some gardens, and is propagated by parting the roots; but this hath little beauty, so is scarce worth cultivating.

CANELLA. See WINTERANA.

CANNABINA. See DATISCA.

CANNABIS [*Kánnabis*, Gr.] Lin. Gen. Plant. 988. Hemp.

The CHARACTERS are,

It is male and female in different plants. The male flowers have a five-leaved empalement which is concave, but have no petals; they have five short hairy stamina, terminated by oblong square summits. The female flowers have permanent empalements of one leaf, which are oblong and pointed. They have no petals, but a small germen, supporting two long styles, crowned by acute stigma; the small germen afterward becomes a globular depressed seed, inclosed in the empalement.

This genus of plants is ranged in the fifth section of Linnæus's twenty-second class, intitled Dioecia Pentandria, the male and female flowers being in separate plants, and the male having five stamina.

We have but one SPECIES of this plant, which is, CANNABIS. Lin. Sp. Plant. 1027. Hemp. Cannabis sativa. C. B. P. 320. *Manured Hemp*. Most of the old writers have applied the latter title to the female Hemp, and the male they have titled Cannabis erratica, or Wild Hemp; but as both arise from the same seeds, so they should not be made different plants.

This plant is propagated in the rich fenny parts of Lincolnshire, in great quantities, for its bark, which is useful for cordage, cloth, &c. and the seeds afford an oil, which is used in medicine.

Hemp is always sown on a deep, moist, rich soil, such as is found in Holland, in Lincolnshire, and the fens in the isle of Ely; where it is cultivated to great advantage, as it might in many other parts of England, where there is the like soil; but it will not thrive on clay, or stiff cold land: it is esteemed very good to destroy weeds, which is no other way effected, but by robbing them of their nourishment; for it will greatly impoverish the land, so that this crop must not be repeated on the same ground.

The land on which Hemp is designed to be sown, should be well ploughed, and made very fine by harrowing; about the middle of April is a good season for sowing the seed: three bushels is the usual allowance for an acre, but two is fully sufficient. In the choice of the seed, the heaviest and brightest coloured should be preferred; and particular care should be had to the kernel of the seed, so that some of them should be cracked to see if they have the germ or future plant perfect; for in some places the male plants are drawn out too soon from the female, i. e. before they have impregnated the female plants with the farina: in which case, though the seeds produced by these female plants may seem fair to the eye, yet they will not grow, as is well known by the inhabitants of Bickar, Swineshead, and Dunnington, three parishes in the fens of Lincolnshire, where Hemp is cultivated in great abundance, who have dearly bought their experience.

When the plants are come up, they should be hoed out in the same manner as is practised for Turneps, leaving the plants a foot or sixteen inches apart; observe also to cut down all the weeds, which, if well performed, and in dry weather, will destroy them. This crop will require a second hoeing about a month or six weeks after the first, in order to destroy the weeds. If this be well performed, it will require no farther care; for the Hemp will soon after cover the ground, and prevent the growth of weeds.

The first season for pulling the Hemp, is usually about the middle of August, when they begin to pull what they call the Fimble Hemp, which is the male plants; but it would be much the better method to defer this a fortnight or three weeks longer, until these male plants have fully shed their dust, without which, the

seeds will prove abortive, produce nothing if sown the next year, nor will those concerned in the oil-mills give any thing for them, there being only empty husks, without any kernels to produce the oil. These male plants begin to decay soon after they have shed their farina.

The second pulling is a little after Michaelmas, when the seeds are ripe: this is usually called Karle Hemp, it is the female plants which were left at the time when the male were pulled. This Karle Hemp is bound in bundles of a yard compass, according to statute measure, which are laid in the sun for a few days to dry; and then it is stacked up, or housed to keep it dry, till the seed can be threshed out. An acre of Hemp on a rich soil, will produce near three quarters of seed, which, together with the unwrought Hemp, is worth from six to eight pounds.

Of late years the inhabitants of the British colonies in North America, have cultivated this useful plant, and a bounty was granted by parliament for the Hemp, which was imported from thence; but whether the inhabitants of those colonies grew tired of cultivating it, or the bounty was not regularly paid, I cannot say; but whatever has been the cause, the quantity imported has by no means answered the expectation of the public, which is greatly to be lamented; because, as this commodity is so essential to the marine, which should be the principal object of this kingdom, the being furnished with it from our own plantations, will not only save the ready money paid for it, but secure to the country an ample supply at all times, without being obliged to our neighbours for it.

CANNACORUS. See CANNA.

CAPERS. See CAPPARIS.

CAPILLAMENTS [*Capillamenta*, Lat.] the strings or threads about the roots of plants.

CAPILLARY plants, [of *Capillaris*, Lat. of, or like hair,] are such plants as have no main stem, but the leaves arise from the root upon pedicles, and produce their seeds on the back of their leaves, as the Fern, Maiden Hair, &c.

CAPITULUM; i. e. a little head; the head or top of any flowering plant.

CAPNOIDES.

CAPNORCHIS. } See FUMARIA.

CAPPARIS. Lin. Gen. Plant. 567. The Caper Bush.

The CHARACTERS are,

The empalement is composed of three oval concave leaves; the flower hath four large roundish petals, which are indented at the top, and spread open; it hath a great number of slender stamina, which are as long as the petals, terminated by single summits. In the midst of these arise a single style longer than the stamina, with an oval germen, crowned by a short obtuse stigma. The germen afterward becomes a fleshy turbinate capsule, with one cell, filled with kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled Polyandria Monogynia, the flower having many stamina and but one style.

The SPECIES are,

1. CAPPARIS (*Spinosa*) pedunculis solitariis unifloris, stipulis spinosis foliis annuis, capsulis ovalibus. Lin. Sp. 720. *Caper with one flower on each foot-stalk, prickly stipula, annual leaves, and oval fruit.* Capparis spinosa, fructu minore, folio rotundo. C. B. P. 480.
2. CAPPARIS (*Baduica*) pedunculis subsolitariis, foliis persistentibus ovato-oblongis nudis determinate confertis. Lin. Sp. 720. *Caper with single foot-stalks, oblong, oval, naked leaves in clusters, which are always green.* Capparis arborescens Indica Baduica dicta. Raii Hist. 1630. *Indian Tree Caper, called Baduica.*
3. CAPPARIS (*Arborescens*) foliis lanceolato-ovatis perennantibus caule arborescenti. *Caper with oval spear-shaped leaves which continue through the year, and a tree-like stalk.*
4. CAPPARIS (*Cynophallophora*) pedunculis multifloris terminalibus angulatis, foliis persistentibus ovalibus obtusis.

obtusis. Lin. Sp. 721. *Caper with angular branches terminated by foot-stalks, having many flowers, and evergreen, obtuse, oval leaves.* Capparis arborescens Lauri foliis fructu longissimo. Plum. Cat. 7. *Tree Caper with Bay leaves, and the longest fruit.*

5. CAPPARIS (*Racemosa*) foliis ovatis oppositis perennantibus floribus racemosis. *Caper with oval leaves placed opposite, which continue through the year, and flowers growing in bunches.*
6. CAPPARIS (*Siliquosa*) pedunculis unifloris compressis, foliis persistentibus lanceolato-oblongis acuminatis subtus punctatis. Lin. Sp. 721. *Caper with compressed foot-stalks having one flower, and oblong, spear-shaped, evergreen leaves, with punctures on their under side.* Breynia arborescens, foliis ovatis utrinque acuminatis, siliqua torosa longissima. Brown. Hist. Jam. 247.
7. CAPPARIS (*Fruticosa*) foliis lanceolatis acutis confertis perennantibus, caule fruticoso. *Caper with pointed spear-shaped leaves growing in clusters, which continue through the year, and a shrubby stalk.*
8. CAPPARIS (*Confertis*) foliis lanceolatis alternis petiolis longissimis floribus confertis. *Caper with spear-shaped leaves placed alternate on very long foot-stalks, and flowers growing in clusters.* Capparis alia arborescens Lauri foliis fructu oblongo ovato. Plum. Cat. 7.
9. CAPPARIS (*Breynia*) pedunculis racemosis, foliis persistentibus oblongis, pedunculis calycibulque tomentosis, floribus octandris. Jacq. Amer. tab. 103. *Caper with branching foot-stalks, oblong evergreen leaves, flowers with eight stamina, whose foot-stalks and cups are woolly.*
10. CAPPARIS (*Triflora*) foliis lanceolatis nervosis perennantibus pedunculis trifloris. *Caper with nervous spear-shaped leaves which continue through the year, and three flowers upon each foot-stalk.*

The first is the common Caper, whose full grown flower-bud is pickled, and brought to England annually from Italy, and the Mediterranean. This is a low shrub, which generally grows out of the joints of old walls, the fissures of rocks, and amongst rubbish, in most of the warm parts of Europe: the stalks are ligneous, and covered with a white bark, which sends out many lateral slender branches; under each of these are placed two short crooked spines, between which and the branches come out the foot-stalk of the leaves, which are single, short, and sustain a round, smooth, entire leaf; at the intermediate joints between the branches, come out the flowers upon long foot-stalks; before these expand, the bud, with the empalement, is gathered for pickling; but those which are left expand in form of a single Rose, having five large, white, roundish, concave petals; in the middle is placed a great number of long stamina, surrounding a style, which rises above them, and is crowned with an oval germen, which afterward becomes a capsule, filled with kidney-shaped seeds.

This sort is cultivated upon old walls about Toulon, and in several parts of Italy. Mr. Ray observed it growing naturally on the walls and ruins at Rome, Sienna, and Florence.

The second sort hath a tree-like stem dividing into branches, which are smooth, having no spines on them; the leaves are oblong, oval, and smooth, which continue through the year. From the wings of the leaves come out the foot-stalks of the flowers, which are produced singly; these flowers are like those of the former, but are much larger, as are also the buds.

The plants of the first sort are with difficulty preserved in England, for they delight to grow in crevices or rocks, and the joints of old walls or ruins, and always thrive best in an horizontal position; so that when they are planted either in pots, or the full ground, they rarely thrive, though they may be kept alive for some years. They are propagated by seeds in the warm parts of Europe, but it is very difficult to get them to grow in England. I have several times sowed these seeds without success, as have many other persons; I never had raised any of the plants from seeds, excepting in the years 1738 and 1765, when I

had three plants come up in an old wall, which being young and tender, were destroyed in the year 1740; but in the year 1765, raised a good number of plants from seeds, which were sown the year before. There is an old plant growing out of a wall in the gardens at Cambden-House, near Kensington, which has resisted the cold for many years, and annually produces many flowers, but the young shoots of it are frequently killed to the stump every winter.

The roots of this plant are annually brought from Italy, by the persons who import Orange-trees, some of which have been planted in walls, where they have lived a few years, but have not continued long.

The third sort I received from Carthage in New Spain, near which place it grows naturally. This rises with a woody stem to the height of twelve or fourteen feet, sending out many lateral branches, covered with a russet bark, garnished with oblong oval leaves, standing upon long foot-stalks; the flowers are produced from the side of the branches, single, standing upon long foot-stalks, which are like those of the last sort.

The fourth sort was sent me from Carthage by the late Mr. Robert Millar, surgeon. This grows with a strong upright trunk near twenty feet high, sending out many lateral branches, garnished with a very white bark, and closely garnished with large, oblong, stiff leaves, of a thicker consistence than those of the common Laurel, of a splendid green, having several transverse nerves from the midrib to the border, which are prominent on their under side; the flowers come out from the side of the branches, which are large, and the summits of the stamina are purple.

The fifth sort was sent me from the same country. This rises with a trunk about twenty feet high, sending out many long slender branches, which are covered with a brown bark, and garnished with leaves like those of the Bay-tree, but longer, and deeply ribbed on their under side, standing upon pretty long foot-stalks opposite. The flowers are produced upon long branching foot-stalks, which terminate the branches, each sustaining two or three flowers, which are large, white, and are succeeded by pods two or three inches long, the thickness of a man's little finger, which are filled with large kidney-shaped seeds: these pods have a thick fleshy cover.

The sixth sort was sent me from Tolu in America. This rises with a shrubby stalk to the height of eight or ten feet, sending out many ligneous branches, covered with a reddish brown bark, garnished with oblong, spear-shaped, stiff leaves, having punctures on their under side; from the wings of the leaves arise the foot-stalks of the flowers, which are long, slender, and compressed, each of which sustains a small white flower, which is succeeded by an oval pod, containing many small kidney-shaped seeds.

The seventh sort rises with a shrubby stem to the height of twelve or fourteen feet, sending out many strong lateral branches, covered with a dark brown bark, garnished with spear-shaped pointed leaves, placed alternately, having very short foot-stalks; the leaves are of a thicker consistence than those of the Bay-tree; at the foot-stalk of each leaf comes out a single flower, almost the whole length of the branches, which are small, and stand upon short foot-stalks; the summits of these flowers are of a purplish colour, but the stamina are white. This sort was sent me from Tolu.

The eighth sort rises with a shrubby stalk to the height of ten or twelve feet, sending out slender horizontal branches, which are covered with a reddish bark; the joints of these branches are far distant; at each of these come out several leaves in clusters, without order, standing upon pretty long foot-stalks; they are six inches long, and three broad in the middle, and as thick as those of the Laurel, of a shining green, smooth on their upper side, but have many transverse ribs on their under side, which are prominent. I received this sort from Tolu, with the former.

The

The ninth sort grows naturally in most of the islands in the West Indies; it hath a strong woody stem, twenty-five or thirty feet high, dividing into many branches, covered with an Ash-coloured bark, and garnished with oblong oval leaves, downy on their under side, but smooth on their upper, placed without order; the flowers are produced in loose panicles at the extremity of the branches; these consist of four pretty large concave petals, of a purple colour, including eight long purple stamina, with a very long style crowned by an obtuse stigma; the germen afterward turns to an oblong fleshy pod, containing four or five seeds.

The tenth sort hath slender shrubby stalks, which rise seven or eight feet high, sending out many ligneous branches, garnished with very long, nervous, spear-shaped leaves. The flowers come out at the end of the branches, three standing upon each foot-stalk; these are small, white, and are succeeded by oval fruit.

These last nine sorts are natives of warm countries, so will not live through the winter in England, without the assistance of a stove. They are propagated by seeds, which must be procured from the countries where they grow naturally, for they do not produce any in England; these must be sown in small pots, filled with light sandy earth, and plunged into a hot-bed of tanners bark; which should be now and then refreshed with water, but by no means should have it given in too great plenty: these seeds frequently remain in the ground a year before they vegetate, therefore the pots in which they are sown should be protected in winter; and the spring following must be plunged into a fresh hot-bed of tanners bark, which will bring up the plants if the seeds were good; when the plants appear they must have but little wet, and a good share of air in warm weather; but when they are large enough to remove, they must be each transplanted into a separate small pot, filled with the same earth, and then plunged into the hot-bed again, observing to shade them until they have taken fresh root; after which they should have fresh air admitted to them every day, in proportion to the warmth of the season. In the autumn they must be removed into the stove, and plunged into the bark-bed, where they should constantly remain, and will require the same treatment as other tender exotic plants from the same countries; with this difference only, that they require but little water, especially during the winter, for the roots of these plants are very subject to rot with wet.

If the seeds are brought over in their capsules, they will keep much better than without them; but these should be secured from insects, by wrapping them in Tobacco leaves which are well dried; without this precaution, the seeds will be destroyed before they arrive.

CAPER [BEAN.] See ZYGOPHYLLUM.

CAPRARIA. Lin. Gen. Plant. 686. Sweet Weed.

The CHARACTERS are,

It hath a permanent empalement of one leaf, cut into five oblong narrow segments, which are erect and stand asunder; the flower is bell-shaped, of one leaf, divided at the top into five equal parts, the two upper standing erect; it hath four stamina, which are inserted in the base of the petal, and but little more than half so long, two of the under being shorter than the other, and terminated by heart-shaped summits; it hath a conical germen supporting a slender style, longer than the stamina, crowned by a bivalve heart-shaped stigma. The germen afterward becomes an oblong conical capsule, compressed at the point, having two cells, divided by a partition filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamina, and the seeds being included in a capsule.

We have but one SPECIES of this genus, viz.

CAPRARIA (*Biflora*) foliis alternis floribus geminis. Jacq.

tab. 15. *Capraria with alternate leaves, and foot-stalks with two flowers.* Capraria Curassavica. Par. Bat. 110.

This plant grows naturally in the warm parts of America, where it is often a troublesome weed in the plantations; it rises with an angular green stalk about a foot and a half high, sending out branches at every joint, which sometimes come out by pairs opposite, but generally there are three at a joint standing round the stalk; the leaves are also placed round the branches by threes; these stand upon short foot-stalks, are oval, hairy, and a little indented on their edges. The flowers are produced at the wings of the leaves, coming out on each side the stalk, each foot-stalk sustaining two flowers; they are white, and succeeded by conical capsules compressed at the top, opening in two parts, and filled with small seeds.

This plant is preserved in botanic gardens for the sake of variety; but as it hath no great beauty, so is seldom admitted into other gardens.

It is propagated by seeds, which must be sown upon a hot-bed in the spring of the year, and the plants must be brought forward by planting them upon a second hot-bed; and about the middle or latter end of June they may be transplanted either into pots of rich earth, or a warm border, and may then be exposed to the open air, where they will perfect their seeds in autumn.

CAPREOLATE plants [of capreolus, Lat. the tendril of a Vine,] such plants as twist and climb upon others, by means of tendrils.

CAPRIFOLIUM. See PERICLYMENUM.

CAPSICUM. Lin. Gen. Plant. 225. [takes its name of capsia, Lat. a chest; because the seeds of this plant are included, as it were, in a little chest; or else of καίω, to bite, because it is a burning pungent plant.] Guinea Pepper; in French, *Poivre d'Inde ou de Guinée*.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, divided into five parts, which are erect. It hath but one petal, which is wheel-shaped, having a very short tube, spread open above, and divided into five parts; it hath five small stamina, terminated by oblong summits, which are connected. It hath an oval germen, supporting a slender style, longer than the stamina, and crowned by an obtuse stigma. The germen afterward becomes a soft fruit, or capsule, of an indeterminate figure, having two or more cells, divided by intermediate partitions, to which adhere many compressed kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and but one style.

The SPECIES are,

1. CAPSICUM (*Annuum*) caule herbaceo; fructu oblongo propendente. *Capsicum with an herbaceous stalk, and an oblong fruit hanging downward.* Capsicum filiquis longis propendentibus. Tourn. Inst. 152.
2. CAPSICUM (*Cordiforme*) caule herbaceo, fructu cordiformi. *Capsicum with an herbaceous stalk, and an heart-shaped fruit.* This is the Capsicum filiqua propendente oblonga & cordiformi. Tourn. Inst. 152.
3. CAPSICUM (*Tetragonum*) caule herbaceo, fructu maximo anguloso obtuso. *Capsicum with an herbaceous stalk, and a large angular obtuse fruit.* Capsicum fructu longo, ventre tumido, per summum tetragonum. Tourn. Inst. 153. *Bell Pepper.*
4. CAPSICUM (*Angulosum*) caule herbaceo, fructu cordiformi anguloso. *Capsicum with an herbaceous stalk, and an angular heart-shaped fruit.* Capsicum filiquis surrectis cordiformibus angulatis. Tourn. Inst. R. H. 153.
5. CAPSICUM (*Cerasiforme*) caule herbaceo, fructu rotundo glabro. *Capsicum with an herbaceous stalk, and a round smooth fruit.* Capsicum filiquis surrectis Cerasi forma. Tourn. Inst. 153.
6. CAPSICUM (*Olivæforme*) caule herbaceo, fructu ovato. *Capsicum with an herbaceous stalk, and an oval-shaped fruit.* Capsicum filiqua olivæ forma. Tourn. Inst. 153.

7. CAPSICUM (*Pyramidale*) caule fruticoso foliis lineari-lanceolatis; fructu pyramidalis erecto luteo. *Capsicum with a shrubby stalk, narrow spear-shaped leaves, and yellow pyramidal fruit growing upright.*
 8. CAPSICUM (*Conoide*) caule fruticoso fructu conico erecto rubro. *Capsicum with a shrubby stalk, and a conical red fruit growing erect, commonly called Hen Pepper.*
 9. CAPSICUM (*Frutescens*) caule fruticoso, fructu parvo pyramidalis erecto. *Capsicum with a shrubby stalk, and a small pyramidal fruit growing erect. Capsicum minus fructu parvo pyramidalis erecto. Sloan. Hist. Jam. vol. i. p. 240. Commonly called Barberry Pepper.*
 10. CAPSICUM (*Minimum*) caule fruticoso, fructu parvo ovato erecto. *Capsicum with a shrubby stalk, and a small oval fruit growing erect, commonly called Bird Pepper.*
- The first is the common long podded Capsicum, which is frequently cultivated in the gardens; of this there is one with red, and another with yellow fruit, which only differ in the colour of their fruit, which difference is permanent; for I have cultivated both sorts many years, and never have found them change from one to the other; but both will vary in the shape of their fruit and their manner of growing, so that the following varieties I have raised from the same seeds, viz.

1. CAPSICUM fructu surrecto oblongo. Tourn. *Capsicum with oblong fruit growing erect.*
2. CAPSICUM fructu bifido. Tourn. *Capsicum with a divided fruit.*
3. CAPSICUM siliquis surrectis & oblongis brevibus. Tourn. *Capsicum with oblong and short pods growing erect.*
4. CAPSICUM fructu tereti spithameo. Tourn. *Capsicum with a taper fruit a span long.*

Of these different forms I have had both the red and yellow, but neither of them have changed their colours, though they have frequently varied in their shape.

The second sort with heart-shaped fruit, is undoubtedly a different species from the first, and never alters toward it, though there are several varieties of this, which arise from the same seeds; of this there are red and yellow fruit, which do not alter in colour, though they produce the following varieties.

1. CAPSICUM siliqua propendente rotunda & cordiformi. Tourn. *Capsicum with round, heart-shaped, hanging pods.*
2. CAPSICUM siliqua latiore & rotundiore. Tourn. *Capsicum with a larger and rounder pod.*
3. CAPSICUM rotundo maximo. Tourn. *Capsicum with the largest round fruit.*
4. CAPSICUM siliquis surrectis cordiformibus. Tourn. *Capsicum with upright heart-shaped pods.*
5. CAPSICUM siliquis surrectis rotundis. Tourn. *Capsicum with round upright pods.*

The third sort I have cultivated many years, and have not found it alter, nor have I seen any other but the red fruit of this. It is the only sort which is proper for pickling, the inside of the fruit being fleshy and tender, whereas those of the other sorts are thin and tough. The pods of this sort are from one inch and a half, to two inches long, are very large, swelling, and wrinkled; flatted at the top, where they are angular, and sometimes stand erect, at others grow downward. When the fruit of this are designed for pickling, they should be gathered before they arrive to their full size, while their rind is tender; then they must be slit down on one side to get out the seeds, after which, they should be soaked two or three days in salt and water; when they are taken out of this and drained, boiling vinegar must be poured on them, in a sufficient quantity to cover them, and closely stopped down for two months; then they should be boiled in the vinegar to make them green; but they want no addition of any sort of spice, and are the wholesomest and best pickle in the world.

The fourth sort is also a distinct species from all the other: this hath broad wrinkled leaves; the fruit is also furrowed and wrinkled, generally growing up-

right, and of a beautiful scarlet colour: some of the fruit will have their tops compressed like a bonnet, from whence it had the name; others upon the same plants will be bell-shaped, but they never alter to any of the other sorts. This is much tenderer than either of the former, so will not ripen its fruit in the open air in England; but if the plants are kept under glasses, without any artificial heat, they will thrive better, and produce more fruit, than in hot-beds or stoves.

The fifth sort was sent me from the Spanish West-Indies: this doth not grow so tall as the other sorts, but spreads near the ground. The leaves come out in clusters, which are of a shining green, and stand on long foot-stalks. The fruit is round, smooth, of a beautiful red, and the size of a common Cherry. I have cultivated this several years, and have not found it change.

The sixth sort I received from Barbadoes: this is like the common in its stalk and leaves, but the fruit is oval, and about the size of a French Olive. I have cultivated this many years, and find it constantly the same.

These six sorts are annual with us, whatever they may be in their native countries, for their stalks decay soon after the fruit is ripe. They are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants have six leaves, they should be transplanted on another hot-bed, at four or five inches distance, shading them in the day time from the sun, until they have taken root, after which, they must have a large share of air admitted to them in warm weather, to prevent their drawing up weak. Toward the end of May, the plants must be hardened by degrees to bear the open air; and in June they should be carefully taken up, preserving as much earth about their roots as possible, and planted into borders of rich earth, observing to water them well, as also to shade them until they have taken root; after which time, they will require no other management, but to keep them clean from weeds, and in very dry seasons to refresh them three or four times a week with water. They will flower the end of June and in July, and their fruit will ripen in autumn. These directions are for the culture of the common sorts of Capsicum, which are generally planted by way of ornament. But the plants of the third sort, which are propagated for pickling, should be planted in a rich spot of ground, in a warm situation, about a foot and a half asunder, and shaded till they have taken root, and afterward duly watered in dry weather; which will greatly promote their growth, and cause them to be more fruitful, as also enlarge the size of the fruit. By this management, there may be at least two crops of fruit for pickling obtained the same year, provided the season proves not too cold; but there should be one plant, whose pods are large and forward, chosen for to save seeds; so the first fruits on this should be suffered to remain, that they may have time to perfect their seeds before the frost comes in autumn, for the early frost generally destroys these plants. When the fruit is fully ripe, it should be cut off, and hung up in a dry room till the spring, when the seeds are wanted.

The fourth, fifth, and sixth sorts being tender, the plants should be put into pots, and placed in an old hot-bed under a deep frame, where they may have room to grow; or if they are planted in the full ground, the plants should be each covered with a bell-glass to screen them from cold. These glasses may be set off every day in warm weather, and placed over them in the evening again; and at such times as the weather is not favourable, the glasses should be raised on the contrary side to the wind, to admit the fresh air. With this care, the fruit of these sorts will ripen in England, which without it, rarely come to maturity, but in very warm seasons.

The beauty of these plants is in their ripe fruit, which being of different forms and colours, intermixed with the green leaves, and white flowers at the same time,

do make a pretty appearance in the latter part of summer, when they are properly disposed in the borders of the flower-garden; or if they are planted in pots, for the decoration of courts, &c. being intermixed with other annual plants, which are in beauty at the same season, they will make an agreeable variety; especially, if as many of the different shaped fruits, of both the red and yellow colours as can be procured, are propagated.

The four last sorts have perennial shrubby stalks, which rise four or five feet high; these are not so hardy as the other, therefore when the plants have been brought forward in the hot-bed, as was directed for the common sorts, they should be each planted in a pot filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance; and in warm weather, they should have a large share of air admitted to them, but must be covered with glasses every night, or in cold weather, and frequently watered. With this management, they will produce plenty of fruit in autumn, which ripen in winter; but they must be removed into the stove, on the first approach of frost, and placed where they may have a temperate warmth, in which they will thrive better than in a greater heat; and the fruit will continue in beauty most part of winter, making a pretty appearance in the stove during that season.

The seeds of the seventh sort I received from Egypt: the leaves of this are much narrower than those of any other sort I have yet seen; the pods always grow erect, and are produced in great plenty, so that the plants make a good appearance for three months in the winter, and they may be preserved two or three years; but as the young plants are the most fruitful, so few persons preserve the old longer, than till they have perfected their fruit, when they begin to lose their beauty. I have cultivated this sort several years, and have never found it vary, so conclude it is a distinct species.

The eighth sort I received from Antigua, by the title of Hen Pepper. This rises with a shrubby stalk three or four feet high, sending out many branches toward the top: the fruit is about half an inch long, shaped in form of an obtuse cone, and of a bright red, growing erect. This ripens its fruit in winter, when it makes a pretty appearance.

The ninth sort grows about the same height as the eighth, but differs from it in the shape and size of the fruit: those of this sort being about the bigness of a Barberry, and nearly of the same shape. This I have long cultivated, and have not observed it to alter.

The tenth sort is commonly known by the title of Bird Pepper in America. This rises with a shrubby stalk four or five feet high: the leaves are broad, and rounder at the ends than those of the other sorts, and of a lucid green: the fruit grows at the divisions of the branches, standing erect: these are small, oval, and of a bright red; they are much more sharp and biting than those of the other sorts. From the fruit of this sort is made the Cayan butter, or what the inhabitants of America call Pepper-pots, which they esteem as the best of all the spices. The following is a receipt for making a Pepper-pot: take of the ripe pods of this sort of Capsicum, and dry them well in the sun, then put them into an earthen or stone pot, mixing flour between every strata of pods, and put them into an oven after the baking of bread, that they may be thoroughly dried; after which, they must be well cleansed from the flour, and if any of the stalks remain to the pods, they should be taken off, and the pods beaten, or ground to fine powder; to every ounce of this, add a pound of Wheat flour, and as much leaven as is sufficient for the quantity intended; after this has been properly mixed and wrought, it should be made into small cakes, and baked in the same manner as common cakes of the same size; then cut them into small parts, and bake them again, that they may be as dry and hard as

biscuit, which, beaten into fine powder and sifted, may be kept for use. This may be used as the common Pepper, to season meat or broth, or for any of the purposes that the ordinary Pepper is used: it gives a better relish to meat or sauce, and is found of excellent use to break and discuss the wind, both in the stomach and the guts; therefore is very proper sauce for such meats as are flatulent and windy, or that breed much moisture or crudity. A scruple of this powder put into chicken or veal broth, is greatly commended for comforting cold stomachs, or dispelling of phlegm or viscous humours, and helping digestion.

Most of the sorts of Capsicum are natives of both the Indies; but they have been brought to Europe from America, where they abound in all the Caribbee islands, and are by the inhabitants greatly used in all their sauces; but especially by the negroes, who are great devourers of them; from whence it had the appellation of Negro Pepper, and probably the title of Guinea Pepper may have been applied to it for the same reason. In Spain and Portugal these fruit are much cultivated, where they are used for the same purposes as in America; but in England, they are chiefly cultivated for ornament, being rarely used for sauce, or in medicine; though it is much used in both, in several other countries.

If the ripe pods of Capsicum are thrown into the fire, they will raise strong and noisome vapours, which occasion vehement sneezing and coughing, and often vomiting, in those who are near the place, or in the room where they are burnt. Some persons have mixed the powder of the pods with snuff, to give to others for diversion; but where it is in quantity, there may be danger in using it, for it will occasion such violent fits of sneezing, as to break the blood-vessels of the head, as I have observed in some to whom it has been given.

CAPSULATE pods [of capsula, *Lat.* a chest] are little, short, dry seed-vessels of plants.

CAPSULATED plants, are such as produce their seeds in short dry pods or husks.

CARACALLA. See **PHASEOLUS**.

CARAGANA. See **OROBUS**.

CARDAMINDUM. See **TROPÆOLUM**.

CARDAMINE. *Lin. Gen. Plant.* 727. [takes its name of Cardamum, which is called Nasturtium; hence it is a small species of Nasturtium,] in English, Ladies Smock.

The **CHARACTERS** are,

The empalement is composed of four oval oblong leaves. The flower hath four oblong petals, placed in form of a cross, which at their base are erect, but spread open above, and are much larger than the empalement; it hath six stamina, four of which are the length of the empalement; the other two, which are opposite, are much longer: these are terminated by oblong, heart-shaped, erect summits. It hath a slender cylindrical germen, as long as the stamina, having no style, but is crowned by an obtuse stigma. The germen afterward turns to a long, compressed, cylindrical pod, with two cells, opening in two valves which twist spirally, and cast out the seeds when ripe, by their elasticity.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradinamia Siliquosa; the flowers of this class have six stamina, four of which are short, and two are longer, standing opposite, and the seeds are included in long pods.

The **SPECIES** are,

1. **CARDAMINE** (*Pratensis*) foliis pinnatis, foliolis radicalibus subrotundis, caulinis lanceolatis. *Lin. Sp. Plant.* 656. *Ladies Smock with winged leaves, whose lobes at bottom are roundish, but those on the stalks are spear-shaped.* Cardamine pratensis magno flore purpurascens. *Tourn. Inst.* 224.
2. **CARDAMINE** (*Parviflora*) foliis pinnatis, foliolis incis, floribus exiguis, caule erecto ramoso. *Ladies Smock with winged leaves, cut lobes, very small flowers, and an upright branching stalk.* Cardamina annua exiguu flore. *Tourn. Inst. R. H.* 224.

3. **CARDAMINE**

3. CARDAMINE (*Hirsuta*) foliis pinnatis, floribus tetrandis. Hort. Cliff. 336. *Ladies Smock, or impatient Cress with winged leaves, and flowers with four stamina.* Cardamine quarta. Dalechamp. Ludg.
 4. CARDAMINE (*Impatiens*) foliis pinnatis incisis stipulatis, floribus apetalis. Lin. Sp. 914. *Impatient Cress with winged leaves, cut stipule, and fugacious flowers.* Cardamine pratensis parvo flore. Tourn. Inst. 224.
 5. CARDAMINE (*Græca*) foliis pinnatis foliolis palmatis æqualibus petiolatis. Prod. Ley. 345. *Impatient Cress with winged leaves, whose lobes are banded, equal, and have foot-stalks.* Cardamine Sicula, foliis Fumaricæ. Tourn. Inst. 225. *Sicilian impatient Cress with Fumitory leaves.*
 6. CARDAMINE (*Amara*) foliis pinnatis, foliolis subrotundis angulosis. Hall. Helv. 558. *Impatient Cress with winged leaves, whose lobes are roundish and angular.* Nasturtium aquaticum majus & amarum. C. B. P. 104.
 7. CARDAMINE (*Trifolia*) foliis ternatis obtusis, caule subnudo. Lin. Sp. Plant. 654. *Three-leaved impatient Cress with a naked stalk.* Nasturtium Alpinum trifolium. C. B. P. 104.
 8. CARDAMINE (*Bellidifolia*) foliis simplicibus ovatis integerrimis petiolis longis, Flor. Lap. 206. *Impatient Cress with single, oval, entire leaves, having long foot-stalks.* Nasturtium Alpinum Bellidis folio minus. C. B. P. 105. *Smaller Alpine Cress with a Daisy leaf.*
 9. CARDAMINE (*Petræa*) foliis simplicibus oblongis dentatis. Lin. Sp. Plant. 654. *Impatient Cress with single, oblong, indented leaves.* Nasturtium petræum. Pluk. Alm. 261. *Rock Cress.*
 10. CARDAMINE (*Chelidonia*) foliis pinnatis foliolis quinis incisis. Lin. Sp. Plant. 655. *Impatient Cress with winged leaves, having five lobes which are cut.* Cardamine glabra Chelidonii folio. Tourn. Inst. 225.
- The first sort grows naturally in the meadows in many parts of England; it is called Cuckow Flower, and Ladies Smock. Of this there are four varieties, viz. the single purple with white flowers, which are frequently intermixed in the meadows, and the double flower of both colours. The single sorts are seldom admitted into gardens; but as the first sort stands in the list of medicinal plants, I have enumerated it. The young leaves of this plant have been gathered in the spring, by some persons, and put into sallads instead of Cress: it is supposed to be an antiscorbutic. The two varieties with double flowers were accidentally found growing in the meadows, and were transplanted into gardens, where they have been propagated. These deserve a place in shady moist borders of the flower-garden, where they will thrive, and make a pretty appearance during their continuance in flower: they are propagated by parting their roots; the best time for this is in autumn, when they should be transplanted annually. They delight in a soft loamy soil, not too stiff, and must have a shady situation. This flowers in May, and in cool seasons will continue part of June.
- The seventh, eighth, and tenth sorts, grow naturally on the Alps, and other mountainous places. I received these from Verona, in the neighbourhood of which place they grow naturally. These are low perennial plants, which may be propagated by parting their roots in the autumn, and require a strong soil and shady situation: they may also be propagated by seeds, which should be sown in the autumn, on a shady border, where they will come up soon after, and are never hurt by frost, so will flower the following season. These varieties are preserved in some gardens, but having little beauty, are seldom admitted into the flower-garden.
- The ninth sort is a low biennial plant, which grows naturally in several parts of England and Wales, and is preserved in some gardens for the sake of variety. It may be propagated by seeds, which should be sown in the autumn, upon poor light ground in an open situation, and will require no other care but to keep the plants clear from weeds. It flowers in June, and the seeds ripen in July.

The sixth sort grows naturally by the sides of rivers and ditches in most parts of England, so is not admitted into gardens. There has been a variety of this found with double flowers, but it is not as yet much known. This flowers the latter end of April, and in May.

The other sorts are low annual plants, which grow naturally in several parts of England, so are seldom admitted into gardens. These have the title of Impatient Cress, from the elasticity of their pods, which, if touched when they are ripe, spring open, and cast out their seeds with violence, to a considerable distance. These sorts when young, are, by the country people, eaten in sallads, and have the flavour of the common Cress, but milder.

These plants, when once admitted into a garden, propagate in plenty; for they produce great quantities of seeds, which, if permitted to scatter, there will be a supply of plants, which only require to be thinned and kept clean from weeds, and will thrive best in the shade.

CARDIACA. See LEONURUS.

CARDINALS FLOWER. See RAPUNTUM.

CARDIOSPERMUM. Lin. Gen. Plant. Heart Pea; by the inhabitants of America called Wild Parsley; by the French, *Pois de Merveille*.

The CHARACTERS are,

It hath a permanent empalement composed of four concave leaves. The flower has four obtuse petals, which are alternately larger; it hath a small four-leaved nectarium encompassing the germen, and eight stamina, three and three standing opposite, the other two on each side; these are terminated by small summits. The germen is three-cornered, and supports three short styles, crowned by single stigma. The germen afterward becomes a roundish swollen capsule with three lobes, divided into three cells, opening at the top, each having one or two globular seeds, marked with a heart.

This genus of plants is ranged in the third section of Linnæus's eighth class, intitled Octandria Trigynia, the flower having eight stamina and three styles.

The SPECIES are,

1. CARDIOSPERMUM (*Corindum*) foliis subtus tomentosis. Lin. Sp. 526. *Heart Pea with woolly leaves.* Corindum folio & fructu minori. Tourn. Inst. 431.

2. CARDIOSPERMUM (*Halicacabum*) foliis lævibus. Hort. Cliff. 150. *Heart-seed with smooth leaves.* Corindum folio ampliori, fructu majore. Tourn. Inst. 431.

The first sort rises with a slender, channelled, climbing stalk, to the height of four or five feet, sending out many side branches, garnished with leaves, upon very long foot-stalks, coming out opposite at the lower part of the stalk; but upward the leaves come out on one side, and the foot-stalk of the flower at the opposite; the foot-stalks of the leaves are divided into three, each of which sustain small leaves, which are again divided into three parts, that are sharply cut on their edges, and end in sharp points. The foot-stalk of the flowers are long, naked, and toward the top, divided into three short ones, each sustaining a single flower. Immediately under these divisions, comes out tendrils or clasps, like those of the Vine, but smaller; these fasten themselves to whatever plants grow near them, and are thereby supported. The flowers are small, white, and composed of four small concave petals, two of which standing opposite, are larger than the other; when these fall away, the germen afterward becomes a large inflated bladder, having three lobes, in each of which is contained one, two, and sometimes three seeds, which are round, hard, and the size of small Peas, each being marked with a black spot in shape of a heart.

The second sort differs from the first in having taller stalks, the leaves being first divided into five, and again into three parts. The foot-stalks are shorter, and the seeds and bladders in which they are contained are much larger, and the whole plant is smoother, in other respects they agree.

These plants grow naturally in both Indies, where they climb upon whatever shrubs are near them, and rise

rise to the height of eight or ten feet, but in England they seldom are much above half so high; they send out many side branches, which spread to a considerable distance every way, and, if permitted, will fasten themselves to the plants which are near them by their small tendrils, and thereby spread over them.

They are annual, and perish soon after they have perfected their seeds, and being natives of hot countries, they will not thrive in England in the open air. They are propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a pot filled with light sandy earth, not too rich, then plunged into a very moderate hot-bed, where they must be carefully shaded until they have taken fresh root; after which they must have a large share of air admitted to them, to prevent their being drawn up tall and weak; and when their roots have filled the pots, they should be carefully shaken out, preserving all the earth to their roots (for if that should fall off, the plants will not survive it;) then put them into pots a little larger, filling them up with the same light earth, and place them either under a deep frame, or behind the plants in the stove, where they may be screened from the sun till they are well settled in the pots; after which they may be removed into a glass-case, where they may have room to grow and be screened from the cold of the nights, but in warm weather they will require a large share of air; with this management they will flower in July, and their seeds will ripen in autumn.

CARDUUS. Lin. Gen. Plant. 832. Thistle, in French, *Chardon*.

The CHARACTERS are,

It hath a compound flower made up of many hermaphrodite florets, which are fruitful; these are included in one common scaly empalement, which is swollen in the middle, each scale ending in a sharp spine; the florets are funnel-shaped, of one leaf, having a slender tube, with an erect brim, cut into five narrow segments; each of these florets have five short hairy stamina, terminated by cylindrical summits, which are indented at the top. In the center is situated an oval germen, crowned with down, supporting a slender style, which is longer than the stamina, crowned with a single, naked, indented stigma. The germen afterward becomes an oblong four-cornered seed, crowned with down, and inclosed by the empalement.

This genus of plants is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia æqualis; the flowers of this class have their summits connected into a cylindrical tube, but the stamina are separate, and those of this section have only hermaphrodite fruitful flowers.

1. CARDUUS (*Ptarmicifolia*) foliis integris subtus tomentosis, spinis ramosis lateralibus. Prod. Leyd. 133. *Thistle with entire leaves, woolly on their under side, and branching spines proceeding from the side of the stalks.* Carduus humilis aculeatus, Ptarmicæ Austriacæ foliis. Triumph. obs. 96.
2. CARDUUS (*Eriophorus*) foliis sessilibus bifariam pinnatifidis laciniis alternis erectis, calycibus globosis villosis. Hort. Upsal. 249. *Thistle with leaves growing close to the stalks, which are doubly pinnated, the segments alternately erect, and globular woolly heads.* Carduus eriocephalus. Dod. Pempt. 723. *Woolly-headed Thistle, called by some Friars Crown.*
3. CARDUUS (*Acarna*) foliis lanceolatis dentatis ciliatis decurrentibus, spinis marginalibus duplicibus. *Thistle with spear-shaped indented leaves running along the stalks, with hairy edges, and the spines double on their borders.* Acarna major caule folioso. C. B. P. 379. *Greater Fish Thistle.*
4. CARDUUS (*Marianus*) foliis amplexicaulibus hastatopinnatifidis spinosis, calycibus aphyllis, spinis canaliculatis duplicato-spinosis. Gouan. Monsp. 422. *Thistle with prickly leaves embracing the stalks, empalements without leaves, and doubly armed with channelled spines.* Carduus Mariæ. Dalech. Hist. 1475. *Our Ladies Thistle, or Milk Thistle.*

5. CARDUUS (*Cirsium*) foliis lanceolatis decurrentibus denticulis inermibus, calyce spinoso. Hort. Cliff. 392. *Thistle with spear-shaped leaves running along the stalks, with smooth indentures, and a prickly empalement.* Cirsium Anglicum. Ger. Emac. 1183. *English soft or gentle Thistle.*

6. CARDUUS (*Casabonæ*) foliis sessilibus lanceolatis integerrimis subtus tomentosis, margine spinis ternatis. Hort. Cliff. 393. *Thistle with entire spear-shaped leaves growing close to the stalks, whose borders are set with triple spines.* Acarna Theophrasti anguillaræ. Lob. Icon. 486. *The supposed true Fish Thistle of Theophrastus.*

There are a great number of species more than are here enumerated, some of which are very troublesome weeds in the gardens and fields, therefore are better to be kept out of both; so I thought it needless to mention them here. The few sorts which I have here enumerated, being often preserved in the gardens of the curious for the sake of variety, or cultivated for use by some persons, therefore chose not to omit them.

The first sort grows naturally in Sicily. This is an annual plant, which rises with a channelled stem about a foot and a half high, sending out several side branches toward the top, garnished with long narrow leaves like those of the Austrian Ptarmica, which are of a deep green above, but white on their under side, placed alternate: just below the foot-stalk of the leaf come out several unequal yellow spines, and at the end of the branches the flowers are produced; these have very prickly empalements, under which are placed two long leaves; the flowers are purple, and shaped like those of the common Thistle, but are smaller; these are succeeded by oblong smooth seeds, which have a long woolly down sitting on their top. This sort flowers in July and August, and the seeds ripen in September. It is propagated by seeds, which should be sown on a bed of light earth in the spring where the plants are to remain, for they do not bear transplanting, unless it is performed when they are very young; for they send long slender roots deep into the ground, which, if broken, the plant seldom survives it. The only care they will require, is to keep them clean from weeds, and thin the plants where they are too close.

The second sort grows naturally in several of the midland counties of England. This is a biennial plant, which sends out many long leaves near the ground, having several long segments, placed alternate, which are joined to a winged border running on each side the mid-rib the whole length; these segments point upward; the under side of the leaves, and the margin of the midrib, are armed with long sharp spines, standing every way. The following spring, there arises from the center of the plant one strong channelled stalk, four or five feet high, branching every way toward the top: the stalk and branches are garnished with the same shaped leaves as below, and each branch is terminated by a single head of purple flowers, having a woolly empalement. This flowers in June and July, and the seeds ripen in the autumn. One or two of these plants may be allowed a place in some abject part of the garden, for its singularity. The seeds of this plant should be sown where the plants are to remain, and will require no other care but to keep them clean from weeds. The second year they will flower, and then the whole plant perishes.

The third sort grows naturally in Spain and Portugal. This rises six feet high; the leaves are long, narrow, and the edges are set closely with small hairs; at every indenture of the leaves there comes out two long yellowish spines; at the end of the branches the flowers are produced from the side of the stalk, which have woolly oval empalements, closely armed with slender spines. The flowers are yellow, but make no great appearance, as they advance very little above the empalement. It flowers in July and August, and the seeds ripen in autumn. This plant may be propagated by seeds in the same

B b b

manner

manner as the former sort. It is called Fish Thistle, from the resemblance which the spines have to the bones of fish.

The fourth sort grows very common on the side of banks, and in waste land in many parts of England, and is by some persons blanchd and dressed as a curious dish. This is a biennial plant, which should be sown very thin, and when the plants are come up so as to be well distinguished, the ground should be hoed, to cut down all the young weeds, and the plants left about a foot and a half distance; and the following summer the ground should be kept clean from weeds. In the autumn the leaves of the plants should be tied up, and the earth drawn up close to blanch them; when they are properly whitened, they will be fit for use. This is a biennial plant, which perishes soon after the seeds are ripe.

The fifth sort is a biennial plant, which is by some cultivated for medicinal use, and has been supposed a remedy for some sort of madness. This may be propagated by seeds in the same manner as the second sort. It grows naturally in the northern parts of England, and flowers in June.

The sixth sort is supposed to be the true Fish Thistle of Theophrastus. This is a biennial plant, which rises with an upright stalk six feet high, garnished with long spear-shaped leaves, armed with triple spines at every indenture on their edges; at the top of the stalks the flowers come out in clusters, which are of a purple colour, and are succeeded by smooth, oval, black seeds. It grows naturally in Sicily and the Levant. It is propagated by seeds as the second sort, which should be sown on a warm border, otherwise the plants will not live through the winter. It flowers in June, and the seeds ripen in autumn.

CARDUUS BENEDICTUS. See CENTAUREA.

CARDUUS FULLONUM. See DIPSACUS.

CARICA. Lin. Gen. Plant. 1000. Papaw, in French *Papaye*.

The CHARACTERS are,

It is male and female in different plants; the flowers of the male have scarce any empalement; they are funnel-shaped, and of one leaf, having a long slender tube, which expands at the top, where it is divided into five narrow obtuse parts, which turn backward; it hath ten stamina, five of which are alternately longer than the other, and are terminated by oblong summits. The female flowers have a small permanent empalement indented in five parts; it hath five long spear-shaped petals; which are obtuse, and turn backward at the top; the oval germen supports five oblong blunt stigma, which are broad at the top, and crenated. The germen afterward becomes a large oblong fleshy fruit, having five longitudinal cells, which are full of small oval furrowed seeds, inclosed in a glutinous pulp.

This genus of plants is ranged in the ninth section of Linnæus's twenty-second class, intitled Diœcia Decandria; the plants of this class have male and female flowers on different plants, and in this section the male flowers have ten stamina.

The SPECIES are,

1. **CARICA** (*Papaya*) foliorum lobis sinuatis. Hort. Cliff. 461. *Papaw with the lobes of the leaves sinuated.* *Papaya fructu Melopeponis effigie.* Plum. *Papaw with the fruit shaped like the Squash.*
2. **CARICA** (*Posoposa*) foliorum lobis integris. Hort. Cliff. 461. *Papaw with the lobes of the leaves entire.* *Papaya ramosa fructu pyriformi.* Feuil. Peruv. 2. p. 52. tab. 39. *Branching Papaw with a Pear-shaped fruit.*

There are several varieties of the first sort, which differ in the size and shape of their fruit. Plumier mentions three of the female or fruitful Papaw, beside the male, one of which he titles Melon-shaped, and the other shaped like the fruit of the Gourd; and I have seen another variety in England, with a large, smooth, pyramidal fruit: but these are supposed to be accidental varieties, which arise from the same seeds.

This sort rises with a thick, soft, herbaceous stem, to the height of eighteen or twenty feet, which is naked till within two or three feet of the top, and hath marks of the vestiges of the fallen leaves great part of its length; the leaves come out on every side the stem upon very long foot-stalks; those which are situated undermost are almost horizontal, but those on the top are erect: these leaves (in full grown plants) are very large, and divided into many parts (or lobes) which are deeply sinuated, or cut into irregular divisions. The whole plant abounds with a milky acrid juice, which is esteemed good for the ringworm: the stem of the plant, and also the foot-stalks of the leaves, are hollow in the middle. The flowers of the male plants are produced from between the leaves on the upper part of the plant, on every side, which have foot-stalks near two feet long, at the ends of which the flowers stand in loose clusters, each having a separate short foot-stalk; these are of a pure white, and have an agreeable odour. They are monopetalous, having pretty long tubes, but are cut at the top into five parts, which twist backward like a screw; sometimes these are succeeded by small fruit, about the size and shape of a Catherine Pear, which has occasioned some to suppose it was a distinct species; but I have frequently raised this, and the female or fruitful sort, from the same seeds, and in general the male flowers fall away, without any fruit succeeding them. The flowers of the female Papaw also come out between the leaves, toward the upper part of the plant, upon very short foot-stalks, singly sitting close to the stem; they are large and bell-shaped, composed of six petals, which are commonly yellow, but those of the pyramidal sort, which I before mentioned, were purple: when these fall away, the germen swells to a large fleshy fruit, the size of a small Melon, which are of different forms; some are angular, and compressed at both ends, others are oval and globular, and some pyramidal; the fruit also abounds with the same acrid milky juice as the plants. This fruit, when ripe, is by the inhabitants of the Caribbee Islands eaten with pepper and sugar as Melons, but are much inferior to our most common Melon in flavour, in its native country; but those which have ripened in England were detestable: the only use I have made known of this fruit, was, when they were about half grown, to soak them in salt water, to get out the milky juice, and pickle them for Mangos, for which they have been a good substitute. These plants are supposed to be natives of America, from whence they were carried to the Philippine Islands, and to several parts of India, where they are now pretty common. Though these plants have been supposed to have male flowers only in some plants, and female on the other, yet I have often seen small fruit on the male plants, and have frequently had fruit on the female, whose seeds have grown as well as any I ever sowed, though no male plants were in the same stove with them.

The second sort was found growing in a garden at Lima, by father Feuillée, and it was the only plant he saw of that sort in his travels. This differs from the other, in having a branching stalk, the lobes or divisions of the leaves being entire, and the fruit being shaped like a Pear, which he says were of different sizes; that which he designed was about eight inches long, and three and a half thick, yellow within and without, and of a sweet flavour. The flower, he says, was of a Rose colour, and divided but into five parts.

These plants being natives of hot countries, will not thrive in England, unless they are preserved in a warm stove; where there are such conveniencies, of a proper height to contain the plants, they deserve a place as well as almost any of the plants which are cultivated for ornament; for when they are grown to a large size, they make a noble appearance with their strong upright stems, which are garnished on every side near the top with large shining leaves, spreading out near three feet all round the stem: the flowers of

of the male sort come out in clusters on every side; and the fruit of the female growing round the stalks between the leaves, being so different from any thing of European production, may intitle them to the care of the curious.

They are easily propagated by seeds, which are annually brought in plenty from the West-Indies. These should be sown in a hot-bed early in the spring, that the plants may obtain strength before the autumn: when the plants are near two inches high, they should be each transplanted into a separate small pot filled with a light, gentle, loamy soil, and plunged into a hot-bed of tanners bark, carefully shading them from the sun till they have taken root; after which they must be treated in the same manner as other tender plants from the same country; but as these plants have soft herbaceous stalks, and abound with a milky juice, they must not have too much water, for they are frequently killed with moisture. There should also be great care taken when these plants are shifted from small pots into larger, to preserve the whole ball of earth to their roots; for whenever they are left bare, they rarely survive it. As the plants advance in their growth, they will require larger pots, and when they are too tall to remain under frames, they must be placed in the tan-bed of the bark-stove, where they should constantly remain, being careful not to give them much water, especially during the winter season; and in summer their waterings should be often repeated, but given in small quantities. With this management I have raised plants near twenty feet high in three years, which have produced their flowers and fruit in great perfection.

CARLINA. Lin. Gen. Plant. 836. The Carline Thistle.

The CHARACTERS are,

It hath a compound flower, made up of many hermaphrodite florets, which are fruitful; these are included in a common, swollen, scaly empalement; the inner scales are long, and placed in a circular order. The flowers are funnel-shaped, having a narrow tube, but are bell-shaped above, and cut into five parts at the brim; these have each five short hairy stamina, terminated by cylindrical summits. In the center is situated a short germen crowned with down, supporting a slender style the length of the stamina, crowned with an oblong bifid stigma. The germen afterward becomes a single taper seed, crowned with a branching plumose down.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis, the flowers being composed of only hermaphrodite florets which are fruitful, whose summits are connected, and form a tube.

The SPECIES are,

1. **CARLINA** (*Vulgaris*) caule multifloro corymboso, floribus terminalibus calycibus radio albis. Hort. Cliff. 395. *Carline Thistle with many flowers in a corymbus, which terminate the stalk, having white rays to the empalement.* Carlina sylvestris vulgaris. Clus. Hist. 2. p. 155. *Common wild Carline Thistle.*
2. **CARLINA** (*Racemosa*) floribus sessilibus, lateralibus paucissimis. Sauv. Meth. 293. *Carline Thistle with a few flowers growing close to the side of the stalk.* Carlina sylvestris minor Hispanica. Clus. Hist. 2. p. 157. *Small wild Spanish Carline Thistle.*
3. **CARLINA** (*Acaulis*) caule unifloro flore brevior. Hort. Cliff. 395. *Carline Thistle with one shorter flower on each stalk.* Carlina acaulos magno flore albo. C. B. P. 380.
4. **CARLINA** (*Lanata*) caule multifloro lanato, calycibus radio purpureis. Lin. Sp. 1160. *Carline Thistle with many downy flowers on a stalk, which have purple rays to their empalement.* Acarna flore purpureo rubente patulo. C. B. P. 372.
5. **CARLINA** (*Corymbosa*) caule multifloro subdiviso, floribus sessilibus calycibus radio flavis. Prod. Leyd. 135. *Carline Thistle with many flowers on a stalk, which is subdivided, the flowers sit close on the stalks, and have yellow rays to their empalement.* Acarna apula umbellata. Colum. Ecphr. 27.

The first sort grows naturally upon sterile ground in most parts of England, so is rarely admitted into gardens. The others are often preserved in botanic gardens for the sake of variety. They grow naturally in the south of France, Spain, and Italy.

They may all be propagated by sowing their seeds in the spring on a bed of fresh undunged earth, where they are designed to remain; for, as they send forth tap roots, they will not bear transplanting so well as most other plants. When the plants appear above ground, they should be carefully weeded; and, as they grow in size, they should be thinned, where they are too close, leaving them about ten inches or a foot asunder. The second year most of these plants will flower; but, unless the summer proves dry, they rarely produce good seeds in England, and most of them decay soon after they have flowered, therefore it is pretty difficult to maintain these plants in this country.

CARNATION. See DIANTHUS.

CARPESIMUM. Lin. Gen. 948. Nodding Starwort.

The CHARACTERS are,

It hath an imbricated empalement, the outer leaves are larger, spreading, and reflexed, the inner are shorter and equal: the flower is equal and compounded; the hermaphrodite florets are funnel-shaped, opening at the top in five parts; these compose the disk. The female florets are tubulous, quinquefid, closing together, which compose the border. The hermaphrodite florets have five short stamina, crowned by cylindrical summits, and an oblong germen, with a single stalk, crowned by a bifid stigma; the female florets have the like, and both are succeeded by oval naked seeds inclosed in the empalement.

This genus of plants is ranged in the second order of Linnæus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers being composed of female and hermaphrodite florets, which are both fruitful.

The SPECIES are,

1. **CARPESIMUM** (*Cernuum*) floribus terminalibus. Lin. Sp. 1203. *Nodding Starwort whose flowers terminate the stalks.* After Cernuus. Col. Ecphr. 1. p. 251.
2. **CARPESIMUM** (*Abrotanoides*) floribus lateralibus. Osb. It. tab. 10. *Nodding Starwort whose flowers come from the side of the stalks.*

The first sort grows naturally in Italy. It is a biennial plant, whose lower leaves are obtuse, woolly, and soft to the touch. The flower-stalk rises from the center of the plant near a foot and a half high, branching toward the top, and garnished with leaves of the same form with those at bottom, but smaller: each of the branches are terminated by one pretty large flower of an herbaceous yellow colour, nodding on one side the stalk; these are composed of female florets which compose the border, and hermaphrodite florets which compose the disk, both which are succeeded by oval naked seeds. This flowers in July, and the seeds ripen in September.

The plant is easily propagated by seeds, which may be sown on a bed of light earth in the spring, and when the plants come up, if they are thinned and kept clean from weeds, they will require no other culture. The second year they will flower and produce seeds, soon after which the plants decay.

The second sort grows naturally in China, and at present is rare in England. This hath a hard branching stalk, garnished with broad spear-shaped leaves slightly crenated on the edges: the flowers are thinly scattered on the side of the stalks and branches, where they sit very close, nodding downward; their empalements are composed of many small leaves which spread open, and inclose a great number of florets.

This may be propagated by seeds, which should be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a single pot; and when the weather becomes warm, they may be exposed, but in autumn they must be housed.

CARPINUS. Lin. Gen. Plant. 952. [so called of carpere, Lat. to crop; because it may be easily cropped, or its wood is easily cleft.] The Hornbeam, or Hardbeam, in French *Charme*.

The CHARACTERS are,

It hath male and female flowers, growing separate on the same plant. The male flowers are disposed in a cylindrical rope or catkin, which is loose and scaly, each scale covering one flower, which hath no petals, but ten small stamina, terminated by compressed hairy summits. The female flowers are disposed in the same form, and are single under each scale; these have one petal, which is shaped like a cup, cut into six parts, and two short germen, each having two hairy styles, crowned by a single stigma. The catkin afterward grows large, and at the base of each scale is lodged an oval angular nut.

This genus of plants is ranged in the eighth section of Linnaeus's twenty-first class, intitled Monœcia Polyandria, the plants of this class having male and female flowers growing separate on the same tree, and those of this section have many stamina.

The SPECIES are,

1. CARPINUS (*Vulgaris*) squamis strobilorum planis. Hort. Cliff. 447. *Hornbeam with flat scales to the cones.* Carpinus. Dod. Pempt. 841. *Common Hornbeam.*
2. CARPINUS (*Ostrya*) squamis strobilorum inflatis. Hort. Cliff. 447. *Hornbeam with inflated scales to the cones.* Ostrya ulmo similis, fructu racemoso lupulo similis. C. B. P. 427. *The Hop Hornbeam.*
3. CARPINUS (*Orientalis*) foliis ovato-lanceolatis serratis strobilis brevibus. *Hornbeam with oval, spear-shaped, sawed leaves, and the shortest cones.* Carpinus Orientalis folio minori, fructu brevi. T. Cor. 40. *Eastern Hornbeam, with a smaller leaf and shorter fruit.*
4. CARPINUS (*Virginiana*) foliis lanceolatis acuminatis, strobilis longissimis. *Hornbeam with pointed spear-shaped leaves, and the longest cones.* Carpinus Virginiana floreſcens. Pluk. *Virginia flowering Hornbeam.*

The first sort is very common in many parts of England, but is rarely suffered to grow as a timber-tree, being generally reduced to pollards by the country people; yet where the young trees have been properly treated, they have grown to a large size. I have seen some of them in woods, upon a cold stiff clay, which have been near seventy feet high, with large, noble, fine stems, perfectly strait and sound. Of late years, this has been only considered as a shrub, and never cultivated but for under-wood in the country, and in the nurseries to form hedges, after the French taste; for in most of their great gardens, their cabinets, &c. are formed of these trees, as are their trellisses and hedges which surround their plantations. But since these sort of ornaments have been almost banished from the English gardens, there has been little demand for these trees in the nurseries.

As this tree will thrive upon cold, barren, exposed hills, and in such situations where few other sorts will grow, it may be cultivated to great advantage by the proprietors of such lands. It will resist the violence of winds better than most other trees, and is by no means slow in its growth. But where these are propagated for timber, they should be raised from seeds, upon the same soil, and in the same situation, where they are designed to grow; and not brought from better land, and a warmer situation, as is too frequently practised. Nor should they be propagated by layers, which is the common method where they are intended for hedges or under-wood; for which those so raised will answer the purpose full as well as those raised from seeds, but the latter must always be preferred for timber-trees.

The seeds of this tree should be sown in the autumn, soon after they are ripe; for if they are kept out of the ground till spring, the plants will not come up till the following year. When the plants appear, they must be kept very clean from weeds, and treated as other forest-trees; in two years time they will be fit to transplant, for the sooner all trees which are designed for timber are planted where they are to remain, the larger they will grow, and the wood will

be firmer and more durable. If these are not intermixed with other kind of trees, they should be planted pretty close; especially on the outside of the plantations, that they may protect and draw each other up: and if they are kept clean from weeds three or four years, it will greatly promote their growth, after which the plants will have obtained sufficient strength to keep down the weeds.

As the trees advance in their growth, they must be thinned, which should be done with caution, cutting away the most unpromising plants gradually, so as not to let much cold air at once, to those which are left, especially on the borders of the plantation. For in all young plantations of timber, it is much the better method, to take away a few trees every year, where it is wanted, than, as is commonly practised, to let all grow till it is fit to cut as under-wood, and then cut all away, except those intended for timber; whereby so much cold air is suddenly let in upon them, as to stop their progress for some years: but by this method a present advantage is gained, which is now more generally attended to, than the future profit.

The timber of this tree is very tough and flexible, and might be converted to many useful purposes, when suffered to grow to a proper size; but as they have been generally treated otherwise, the principal uses it has been applied to, was for turnery ware, for which it is an excellent wood, and also for making mill-cogs, heads of beetles, &c. It is also excellent fuel. The leaves of this tree remain upon them, till the young buds in the spring thrust them off, so they afford much shelter to birds in winter; and this renders them very proper to plant round the borders of other plantations in exposed situations, where they will defend the other trees in winter, and thereby greatly promote their growth.

The Hop Hornbeam sheds its leaves in winter, with the Elm, and other deciduous trees. This tree, tho' but lately much known in England, is very common in Germany, growing promiscuously with the common sort. It is also said to grow plentifully in many parts of North America, but it is doubtful whether that is not a different sort from this. The Hop Hornbeam is of quicker growth than the common sort, but what the wood of that will be I do not know; for there are but few of the trees in England growing upon their own roots, most of them having been grafted upon the common Hornbeam, which is the usual method of propagating them in the nurseries; but the trees so raised are of short duration, for the graft generally grows much faster than the stock, so that in a few years there is a great disproportion in their size; and where they happen to stand exposed to strong winds, the graft is frequently broken from the stock, after many years growth; for which reason, I would caution every person not to purchase any of these trees which have been so propagated.

The Virginian flowering Hornbeam is still less common than the last, and only to be seen in curious gardens; it is equally as hardy as the other, and may be increased by layers.

This sort will grow to the height of thirty feet, or more, and is of quicker growth than either of the former sorts: it sheds its leaves in autumn, about the same time with the Elm; and, during the time of its verdure, this tree makes a good appearance, being well clothed with leaves, which are of a deep, strong, green colour, resembling more the long-leaved Elm than the Hornbeam.

The Eastern Hornbeam is a tree of humble growth, rarely rising above ten or twelve feet high in this country, shooting out many horizontal irregular branches, so cannot easily be trained up to a stem. The leaves of this sort are much smaller than those of the common Hornbeam, and the branches grow closer together, therefore may be very proper for low hedges, where they are wanted in gardens; being a very tonfile plant, it may be kept in less compass than

than almost any deciduous tree. It is as hardy as any of the sorts, and may be propagated in the same manner; but at present it is rare in the English nurseries.

CARROTS. See DAUCUS.

CARTHAMUS. Lin. Gen. Plant. 838. [so called of καθάρειν, Gr. to purge, because the seeds of it are purging,] Bastard Saffron, or Safflower in French; *Cartame, ou Saffran Batard*.

The CHARACTERS are,

It hath a flower composed of several hermaphrodite florets, included in one common scaly empalement. The scales are composed of many flat leaves, broad at their base, ending in a spine, and spread open below. The florets are funnel-shaped, of one leaf, cut into five equal segments at the top; these have five short hairy stamina, terminated by cylindrical tubular summits; in the center is situated a short germen, supporting a slender style the length of the stamina, crowned by a single stigma. The germen afterward becomes a single, oblong, angular seed, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Æqualis; the flowers of this section being composed of only fruitful florets, and their summits are connected in form of a cylindrical tube.

The SPECIES are,

1. CARTHAMUS (*Tinctorius*) foliis ovatis integris serrato-aculeatis. Hort. Cliff. 394. *Bastard Saffron with oval entire leaves, which have spiny serratures. Carthamus officinarum, flore croceo. Tourn. Inst. 457. Bastard Saffron of the shops, with a Saffron-coloured flower.*
2. CARTHAMUS (*Lanatus*) caule piloso supernè lanato, foliis inferioribus pinnatifidis, summis amplexicaulibus dentatis. Hort. Upsal. 251. *Carthamus with a hairy stalk, woolly above, the under leaves indented, and the upper embracing the stalk. Atractylis lutea. C. B. P. Yellow Distaff Thistle.*
3. CARTHAMUS (*Creticus*) caule læviusculo, calycibus sublanatis, flosculis subnovenis, foliis inferioribus lyratis, summis amplexicaulibus dentatis. Lin. Sp. 1163. *Carthamus with a smooth stalk, woolly empalements, generally nine florets, the under leaves lyre-shaped, and the upper embracing the stalk. Cnicus Creticus Atractylidis folio & facie, flore leucophæo. Tourn. Cor. 33.*
4. CARTHAMUS (*Tingitanus*) foliis radicalibus pinnatis, caulinis pinnatifidis, caule unifloro. Lin. Sp. 1163. *Carthamus whose radical leaves are winged, those on the stalks wing-pointed, and one flower on a stalk. Cnicus perennis cæruleus Tingitanus. H. L. 162. Blue perennial Cnicus of Tangier.*
5. CARTHAMUS (*Carduncellus*) foliis caulinis linearibus pinnatis longitudine plante. Lin. Sp. Plant. 831. *Carthamus with narrow winged leaves on the stalks, which are as long as the plant. Cnicus cæruleus humilis Montis Lupi. H. L. Dwarf Cnicus of Mount Lupus with a blue flower.*
6. CARTHAMUS (*Cæruleus*) foliis lanceolatis spinoso-dentatis, caule subunifloro. Hort. Cliff. 1163. *Carthamus with spear-shaped leaves prickly indented, and one flower on each stalk. Cnicus cæruleus asperior. C. B. P. 378. Rougher blue Cnicus.*
7. CARTHAMUS (*Arborescens*) foliis ensiformibus sinuato-dentatis. Prod. Leyd. 136. *Carthamus with sword-shaped leaves which are sinuated and indented. Cnicus Hispanicus arborescens fœtidissimus. Tourn. Inst. 451. Stinking shrubby Cnicus of Spain.*
8. CARTHAMUS (*Corymbosus*) floribus umbellatis numerosis. *Carthamus with many flowers in umbels. Chamæleon niger umbellatus, flore cæruleo hyacinthino. C. B. P. 380. Black umbellated Chamæleon with blue flowers.*

The first sort grows naturally in Egypt, and in some of the warm parts of Asia. I have frequently received the seeds of this from the British islands in America, but whether they were originally carried thither, or if it grows naturally there, I could never be rightly informed. It is at present cultivated in many parts of Europe, and also in the Levant, from whence great quantities of Safflower are annually imported to England, for dyeing and painting.

This is an annual plant, which rises with a stiff ligneous stalk two feet and a half, or three feet high, dividing upward into many branches, which are garnished with oval pointed leaves, sitting close to the branches: these are entire, and are slightly sawed on their edges, each tooth being terminated by a short spine. The flowers grow single at the extremity of each branch: the heads of flowers are large, inclosed in a scaly empalement; each scale is broad at the base, flat, and formed like a leaf of the plant, terminating in a sharp spine. The lower part of the empalement spreads open, but the scales above closely embrace the florets, which stand out near an inch above the empalement; these are of a fine Saffron colour, and this is the part which is gathered for the uses above-mentioned. When the florets decay, the germen which is situated in each, become single, oblong, angular seeds, of a white colour, and have a pretty strong shell or cover to them. It flowers in July and August, and the seeds ripen in autumn; but if the season proves cold and moist, when the plants are in flower, there will be no good seeds produced; so that there are few seasons, wherein the seeds of this plant do come to perfection in England.

The seeds of this plant are sometimes used in medicine, and are accounted a pretty strong cathartic, but at present they are seldom prescribed. It is propagated by seeds, which should be sown in April, upon a bed of light earth: the best way is to sow them in drills, drawn at two feet and a half distance from each other, in which the seeds should be scattered thinly, for the plants must not stand nearer each other than a foot in the rows; but as some of the seeds will fail, so a greater quantity should be sown, as it will be easy to thin the plants, at the time when the ground is hoed. If the seeds are good, the plants will appear in less than a month; and in a fortnight or three weeks after, it will be proper to hoe the ground to destroy the weeds, and at the same time the plants should be thinned where they are too close; but at this time they should not be separated to their full distance, lest some of them should afterward fail; so that if they are now left six inches asunder, there will be room enough for the plants to grow, till the next time of hoeing, when they must be thinned to the distance they are to remain for good: after this they should have a third hoeing, which, if carefully performed in dry weather, will destroy the weeds and make the ground clean, so that the plants will require no farther care, till they come to flower; when, if the Safflower is intended for use, the florets should be cut off from the flowers as they come to perfection; but this must be performed when they are perfectly dry, and then they should be dried in a kiln, with a moderate fire, in the same manner as the true Saffron, which will prepare the commodity for use.

But if the plants are designed for seed, the flowers must not be gathered; for if the florets are cut off, it will render the seeds abortive, though they may swell and grow to their usual size, as I have frequently experienced; yet when they are broken, there will be found nothing more than a shell without any kernel. And this frequently happens to be the case with these seeds, in wet cold seasons; though in very wet years the germen will rot, and never come so forward as to form a shell.

I have been informed, that this plant was formerly cultivated in the fields in several parts of England, for the dyers use; and particularly in Gloucestershire, where the common people frequently gathered the florets, and dried them, to put into their puddings and cheescakes, to give them a colour; but some by putting it in too great quantity, gave their puddings a cathartic quality.

If this plant was ever cultivated here in great quantity, it is surprising how it came to be so totally neglected, as that at present, there are not the least traces to be met with, in any part of England, of its ever having been cultivated; nor is the commodity

scarce known, except to those who deal in it: the quantity of this which is annually consumed in England is so great, as to make a very considerable article in trade, so that it might be very well worthy of the public attention; for although the seeds seldom come to perfection in England, yet these might be annually procured from abroad, and the plants would constantly produce the flower, which is the only part useful. A few years past I sent a small parcel of the seeds of this plant to South Carolina, where I was afterward informed it grew amazingly, for in six weeks after the seeds were sown, the crop of Safflower was fit to cut, and the gentleman to whom the seeds were given, sent some of the commodity to his brother in London, who was so kind as to send me a specimen of it, with an account that the dyers complained of its want of colour; and upon examining it, I found the florets were drawn out of their empalements the whole length, so that their tails which had been included in their covers were white, and being mixed together gave the whole a pale appearance; upon this I wrote to the gentleman to desire he would cut off the upper part of the florets with scissars, which would be easier performed, but have heard nothing from him since; however, a year or two after I received a letter from his excellency Governor Lyttleton, in which he wrote that the Safflower bid fair to prove one of their great branches of commerce, but how it has turned out I have not since heard.

This plant is cultivated in great plenty, in some parts of Germany, where the seeds constantly come to perfection; and as I have obtained a short account of their method of cultivation, from a curious gentleman of that country, so I shall insert it for the benefit of those who may be induced to engage in this undertaking.

The ground in which they propose to sow the *Carthamus*, has always a double fallow given to it, first to destroy the weeds, and afterward to make it fine. They make choice of their lightest land, and such as is clear from Couch Grass, and other troublesome weeds. After the land has been fallowed a summer and winter, in which time they give it four ploughings, and harrow it between each, to break the clods, and pulverize it: in the latter end of March they give it the last ploughing, when they lay it in narrow furrows of about five feet or a little more, leaving a space of two feet between each: then they harrow these lands to make them level, and after it is finished, they sow the seeds in the following manner. With a small plough, they draw four shallow furrows in each land, at near a foot and a half distance, into which they scatter the seeds thinly; then with a harrow, whose teeth are little more than one inch long, they draw the earth into the drills to cover the seeds; after this, they draw a roller over the ground, to smooth and settle it. When the plants are come up, so as to be distinguished, they hoe the ground to destroy the weeds; and at this first operation, where the plants happen to be close, they cut up the least promising, leaving them all single, at the distance of three or four inches; which they always suppose will be sufficient room for their growth, till the second time of hoeing, which must be performed in about five weeks after their first; in which they are guided by the growth of the weeds, for as this work is performed with a Dutch hoe, so they never suffer the weeds to grow to any size before they cut them; in which they judge right, for when the weeds are small, one man will hoe as much ground in a day, as can be performed by three, when they are permitted to grow large; and the weeds will be more effectually destroyed.

They give a third hoeing to the plants, about five or six weeks after the second; which generally makes the ground so clean, as to require no more cleaning, till the *Carthamus* is pulled up. When the plants begin to flower, and have thrust out their florets (or thrum) to a proper length, they go over the ground once a week to gather it; and as it is from time to

time gathered, it is dried in a kiln for use. There is usually a succession of flowers for six or seven weeks. After the crop is gathered, the stalks are pulled, and tied in bundles for fuel; and when they have been set up a few days to dry, they are carried off, and the ground is ploughed for Wheat; which they say, always succeeds well after this plant.

The good quality of this commodity is chiefly in the colour, which should be of a bright Saffron colour; and herein that which is cultivated in England often fails; for if there happens much rain during the time the plants are in flower, it will cause the florets to change to a dark or dirty yellow, which will also befall that which is gathered when there is any moisture remaining upon it; therefore great care must be taken not to gather it till the dew is quite dried off, nor should it be pressed together till it has been dried on the kiln. The manner of doing this being the same as for the true Saffron, I shall not mention it here, but desire the reader to turn to the article *Crocus*, where that is fully treated.

In Spain this plant is cultivated in their gardens, as Marigolds are in England, to put into their soups, olios, and other dishes, to give them a colour. The Jews also are very fond of this, and mix it in most of their viands; and it is very probable they were the persons who first carried the seeds of this plant to America, and taught the inhabitants the use of it, for it is now as commonly used by the English there, as in any part of Europe.

This plant may be admitted to have a place in the borders of large gardens, where it will add to the variety, during the time of its continuance in flower, which is commonly two months, or ten weeks; for if the seeds are sown in the beginning of April, the first flowers will appear in the middle of July at farthest; and there will be a succession of flowers on the side branches, till the end of September, or in mild warm seasons till the middle of October, during which time the plants will not be destitute of flowers; which being of a bright Saffron colour, make a pretty appearance; and if the plants are supported to prevent their being broken, or blown down by the wind, they will not interfere with the other flowers, because these have a regular upright growth.

When they are cultivated for this purpose, the seeds should be sown in the places where the plants are designed to remain, because they do not bear transplanting well; therefore three or four seeds should be sown in each patch, lest any of them should fail; and when the plants are grown so strong as to be out of danger, the most promising in each patch should be left, and the others pulled up, that they may not draw or injure those which are to stand.

The second sort grows naturally in the south of France, Spain, and Italy, where the women use the stalks of this plant for distaffs, from whence it had the title of Distaff Thistle. It is by some called Bastard wild Saffron. The leaves of this plant are sometimes ordered for medicine, and are supposed to have the same virtues as *Carduus Benedictus*.

This plant is annual, perishing soon after the seeds are ripe; the lower leaves spread flat upon the ground; these are five or six inches long, narrow, and deeply indented on both sides; they are hairy, and have a few soft spines on their edges; the stalk rises about two feet high, covered with hairs, and garnished with oblong hairy leaves, which embrace the stalk with their base, and are deeply sinuated, with sharp thorns growing on their edges. The upper part of the stalk divides into many branches, which are garnished with leaves of the same form, but smaller. The flowers are produced at the end of the branches, having a cluster of stiff, hard, prickly leaves below the scaly empalement, which contains many yellow hermaphrodite flowers, succeeded by oblong angular seeds. It flowers in June and July, and the seeds ripen in autumn. If the seeds of this sort are sown in autumn, the plants will flower early the following summer, so there will be a certainty of good seeds. They may

may be sown upon a bed of earth in any situation, and will require no other culture, but to keep them clean from weeds, and thin the plants where they are too close; this being a medicinal plant, is kept in some gardens, but it hath little beauty.

There is a variety of this, which grows much taller, the heads are larger, and the leaves are placed closer upon the stalks. This was found by Dr. Tournefort in the Levant.

The third sort was also discovered by Tournefort in the island of Crete, from whence he sent the seeds to the royal garden at Paris. This differs from the former, in having a smooth stalk; the leaves are very stiff, deeply indented, smooth, and are armed with very strong spines; the heads of flowers are oval, the florets white, and the plant grows near four feet high. This is an annual plant, which may be sown and treated in the same way as the former, and flowers about the same time.

The fourth sort hath a perennial root, but an annual stalk. This grows naturally in Spain, and was first brought to England from Tangier; the seeds of this are never perfected in England, so it is propagated by parting of the roots. The best time for transplanting and parting them, is about the beginning of March; they should have a dry soil and a warm situation, otherwise they are liable to be destroyed in severe winters.

The stalks of this rise about a foot and a half high, seldom putting out any branches, garnished with narrow spear-shaped leaves the whole length of the stalk; these are deeply sawed on their edges, each of the serratures ending in a sharp point. The stalk is terminated by one large scaly head of blue flowers, shaped like those of the other species.

The fifth sort grows naturally in the south of France, Spain, and Italy. This hath a perennial root and an annual stalk, which rises about six inches high; it is channelled, hairy, and garnished with long narrow leaves, ending in several sharp spines; their edges are indented, each indenture ending in a spine. Each stalk is terminated by one large head of blue flowers, having a leafy empalement, composed of very broad scales, each ending in a sharp spine. It flowers in June.

This sort is difficult to propagate in England, for the roots do not put out offsets like the former, so it is only to be raised from seeds; which do not come to perfection here, unless the season proves warm and dry. This plant should have a dry soil and a warm situation.

The sixth sort is supposed by some, to be the same with the fourth, which is a great mistake, for they are extremely different. This rises with a single stalk about two feet high, which is of a purplish colour, hairy, and channelled, closely garnished with broad spear-shaped leaves, which are sharply sawed on their edges, and covered with a short hairy down. The stalk is terminated by a single large head of blue flowers, having a scaly empalement, composed of two orders of leaves, the outer being broad, long, and armed with sharp spines on their edges; the inner are narrow, and terminate with a sharp thorn. It flowers in June and July, and the seeds ripen in autumn. This sort may be propagated by parting of their roots, which should be performed in autumn, when the leaves decay. It should have a light dry soil, in which it will endure the cold of our winters, and continue many years. It may also be propagated by seeds, which ripen well in dry seasons, but in wet summers the seeds are generally abortive; this requires no other care but to keep it clean from weeds. It grows naturally in Spain, France and Italy, on arable land.

The seventh sort I received from Andalusia, where it grows naturally in great plenty. This rises with a shrubby perennial stalk to the height of eight or ten feet, dividing into many branches, garnished with pretty long sword-shaped leaves, which are indented, armed with spines on their edges, and embrace the

stalks with their base. The branches are terminated by large, scaly, prickly heads of yellow flowers, which come out in July, but are never succeeded by seeds in this country, so can only be propagated by side shoots, slipped from the branches in the spring, and planted in pots filled with light sandy earth, and plunged into a moderate hot-bed, observing to shade them till they have taken root; then they must be gradually hardened, and removed into the open air, and when they have obtained strength, they may be separated, and some of them planted in a warm dry border, where they will endure the cold of our ordinary winters; but, in severe frost, they are frequently destroyed; therefore a plant or two should be kept in pots, and sheltered in winter to preserve the species.

The seeds of the eighth sort were sent me from Spain, where it grows naturally. This hath a perennial root but an annual stalk, which is single, and never puts out any side branches; these are white, smooth, and channelled. The leaves are long, narrow, of a pale green, and closely armed on their edges with short stiff spines, which come out double. The stalks are terminated by single, oval, scaly heads of white flowers, each scale being terminated by a purplish spine. This squamous empalement is closely joined at the top, so as few of the hermaphrodite florets appear visible above it; and this is guarded by a border of long, narrow, prickly leaves, surrounding the head, which rise considerably above the flowers. This plant flowers in July and August, but seldom perfects its seeds in England. It should be planted in a light soil and a warm situation, where it will live abroad in our ordinary winters, but in severe frost it is sometimes destroyed. As the seeds of this sort rarely ripen in England, the only method to propagate the plant, is by parting the roots in the spring.

CARUM. Lin. Gen. Plant. 327. Carvi [so called of Κάρις, Gr. the head, as though good for the head; but others derive the name from Caria, where the ancients found this plant.] Carui, or Carraway.

The CHARACTERS are,

It hath an umbellated flower, composed of several small umbels; which are formed as rays to the general umbel, neither of which have any involucre; the single flowers have very small empalements; each hath five heart-shaped obtuse petals, turned inward at their points; it hath five hairy stamina the length of the petals, terminated by roundish small summits. The germen is situated under the flower, supporting two small styles, crowned by a single stigma. The germen afterward becomes an oblong channelled fruit, dividing into two parts, each having an oblong furrowed seed.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Dygynia, the flowers having five stamina and two styles.

The SPECIES are;

1. CARUM (*Carvi*) foliis pinnatifidis planis, umbellatis inæqualibus confertis. Carraway with plain leaves ending with many points, and unequal umbels, growing close. Cuminum pratense, Carui officinarum. C. B. P. 159. Meadow Cumin, or Carraway of the shops.
2. CARUM (*Hispanicum*) foliis capillaribus multifidis, umbellis laxis. Carraway with capillary multifid leaves, and loose umbels. Carvi Hispanicum, semine majore, & latiore. Juss. Spanish Carraway with a larger and broader seed.

The first sort is the common Carraway, whose seeds are greatly used, not only in medicine, but also in the kitchen, &c. This grows naturally in some rich meadows in Lincolnshire and Yorkshire, and is sometimes found growing in the pastures near London. It is also cultivated for use in Essex, and some other counties.

This is a biennial plant, which rises from seeds one year, flowers the next, and perishes soon after the seeds are ripe. It hath a taper root like a Parsnep, but much smaller, which runs deep into the ground, and hath a strong aromatic taste, sending out many small fibres; from the root arise one or two smooth, solid,

solid, channelled stalks, about two feet high, garnished with winged leaves, having long naked foot-stalks, and many small wings placed opposite on the midrib, which are composed of many narrow, little, plain leaves, ending in several points. The stalks divide upward into several smaller branches, each of which is terminated by an umbel, composed of six or eight small separate umbels or rays, which divide into several small foot-stalks, each sustaining a single white flower, with five heart-shaped petals; the flowers of these small umbels are closely joined together. After the flowers are decayed, the germen becomes an oblong channelled fruit, composed of two oblong channelled seeds, plain on one side, but convex on the other. It flowers in June, and the seeds ripen in autumn.

The best season for sowing the seeds of this plant is in autumn, soon after they are ripe, when they will more certainly grow, than those sown in the spring; and the plants which rise in the autumn, generally flower the following season, so that a summer's growth is hereby saved. When the plants come up, the ground should be hoed to destroy the weeds; and where the plants are too close, they must be thinned in the same manner as is practised for Carrots, leaving them three or four inches apart. In the following spring they will require to be twice more hoed, which will keep the ground clean till the seeds are ripe; then the stalks must be pulled up, and tied in bundles, setting them upright to dry, when the seeds may be threshed out for use.

The second sort grows naturally in Spain: the seeds of this were sent me from the royal garden at Paris. This plant rises with a stronger stalk than the former, which seldom grows more than a foot and a half high, but is closely garnished with fine narrow leaves like those of Dill; the stalks divide upward into many branches, each being terminated by loose umbels of white flowers, which are succeeded by large broad seeds, having the same aromatic flavour as the common sort. This is a biennial plant, and may be treated in the same manner as the former.

CARYOPHYLLATA. See **GEUM**.

CARYOPHYLLUS. Lin. Gen. 594. Caryophyllus aromaticus. Tourn. Inst. R. H. 661. tab. 432. *The Clove-tree, or All-spice.*

The **CHARACTERS** are,

It hath a double empalement, that of the flower is of one leaf, cut into four obtuse parts, upon which the germen is situated; the fruit hath another empalement, which is small, and slightly divided into four parts, which are permanent. The flower hath four blunt petals, which are situated opposite to the incisures of the empalement. It hath many stamina, which rise from the sides of the empalement, terminated by roundish summits. The germen is situated under the flower, and is crowned by the small empalement, supporting a single upright style, crowned by an obtuse stigma. The germen afterward becomes a soft berry with two cells, each containing a single kidney-shaped seed.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled Polyandria Monogynia, the flower having many stamina and but one style.

The **SPECIES** are,

1. **CARYOPHYLLUS** (*Aromaticus*) foliis ovato-lanceolatis oppositis, floribus terminalibus, staminibus corollâ longioribus. *The Clove-tree with oval spear-shaped leaves growing opposite, and flowers terminating the stalks, whose stamina are longer than the petals.* Caryophyllus aromaticus fructu oblongo. C. B. P. 410. *Aromatic Clove with an oblong fruit.*
2. **CARYOPHYLLUS** (*Pimento*) foliis lanceolatis oppositis, floribus racemosis terminalibus, & axillaribus. *Clove-tree with spear-shaped leaves growing opposite, and flowers growing in bunches at the ends of the branches, and wings of the leaves.* Myrtus arborea aromatica foliis laurinis. Sloan. Cat. 161. *The Pimento, or All-spice.*
3. **CARYOPHYLLUS** (*Fruticosus*) foliis lanceolatis opposi-

tis, floribus geminatis alaribus. Brown. Hist. Jam. 248. *Clove-tree with spear-shaped leaves placed opposite, and flowers growing by pairs from the sides of the stalks.*

4. **CARYOPHYLLUS** (*Cotinifolia*) foliis ovatis obtusis oppositis, floribus sparsis alaribus. *Clove-tree with oval blunt leaves placed opposite, and flowers growing thinly from the sides of the branches.* Myrtus cotini folio. Plum. Cat. 19. *Myrtle with a leaf of Venice Sumach.*

5. **CARYOPHYLLUS** (*Racemosus*) foliis oblongo-ovatis, emarginatis, rigidis, glabris, floribus racemosis terminalibus. *Clove-tree with oblong oval leaves, which are stiff, smooth, and indented at the edges, and flowers growing in branches terminating the stalk.*

The first sort grows naturally in the Moluccas, and the hottest parts of the world, where it rises to the height of a common Apple-tree; but the trunk generally divides at about four or five feet from the ground into three or four large limbs, which grow erect, and are covered with a thin smooth bark, which adheres closely to the wood. These limbs divide into many small branches, which form a sort of conical figure; the leaves are like those of the Bay-tree, and are placed opposite on the branches. The flowers are produced in loose bunches at the end of the branches, which are small, white, and have a great number of stamina, which are much longer than the petals. The flowers are succeeded by oval berries, which are crowned with the empalement, divided into four parts, which spread flat on the top of the fruit, in which form they are brought to Europe; for it is the young fruit beaten from the trees before they are half grown, which are the Cloves used all over Europe.

I have not heard of any plants of this kind being in the gardens, either in England or Holland, but I chose to mention it here, to introduce the other.

The second sort grows naturally in Jamaica, but particularly on the north side of that island, where it is found in great plenty, and is a considerable branch of their trade; the unripe fruit dried, being the All-spice so well known in Europe. It is now cultivated with care in many of the plantations, for the trees will thrive upon shallow rocky land, which is unfit for the Sugar-cane; so that a great advantage arises to the planters from those lands, which would otherwise be of small account to them.

This tree grows to the height of thirty feet or more, with a strait trunk, covered with a smooth brown bark, dividing upward into many branches which come out opposite, garnished with oblong leaves, resembling those of the Bay-tree in form, colour, and texture, but are longer, and are placed by pairs: when these are bruised or broken, they have a very fine aromatic odour like that of the fruit. The branches grow very regular, so that the trees make a fine appearance, and as they retain their leaves through the year, the trees are worthy of being propagated for ornament and shade about the habitations of the planters. The flowers are produced in large loose bunches from the side of the branches, towards their ends, each branch is also terminated by a larger bunch than the other; the flowers are small, and of an herbaceous colour; they are male and female upon distinct trees. I was favoured with fine samples of both, and also a particular account of the trees, by William Williams, Esq; of St. Anne's, on the north side of Jamaica, who has the greatest number of these trees on his plantation of any person in that island. The male flowers have very small petals, and a great number of stamina in each, which are of the same colour with the petals, terminated by oval bifid summits; the female flowers have no stamina, but an oval germen, situated below the flower, supporting a slender style, with a blunt stigma at the top. The germen afterward becomes a globular pulpy berry, including two kidney-shaped seeds. The usual season when these trees flower, is in June, July, and August.

When

When the fruit of these trees are designed for use, they are gathered, or beaten down from the trees a little before they arrive to their full size, and are separated from leaves, stalks, or any rubbish which may have accidentally mixed with them; then the fruit is exposed every day to the sun, spread on cloths for ten or twelve days to dry, but removed under cover every evening to screen it from the dews; when the fruit is perfectly dry, it is packed up for exportation. If the fruit is permitted to grow to maturity, the pulp, which surrounds the seeds, is so full of moisture, and is so glutinous, as to stick to the fingers of those who bruise them, therefore are unfit for those uses to which the dried fruit are applied.

It is called by some Jamaica Pepper, but the most general appellation is All-spice, from its relish and flavour, partaking of many other spices, and is deservedly accounted one of the best; and if it was as scarce and difficult to procure as those spices in the east, would be much more sought after and esteemed: our neighbours the Dutch, who have engrossed the spice trade to themselves, have also been artful enough to deceive us with this of our production, by purchasing the dried fruit of the All-spice in England at a low price, and grinding it to a powder, then selling it to us at an advanced price for powder of Cloves. This I have been credibly informed of, by an eminent merchant, through whose hands great quantities of this commodity have passed.

The Dutch have also drawn an oil from the fruit of this tree, which they vend for oil of Cloves. I had a small phial of this oil sent me from Jamaica, which was shewn to some of the best judges of drugs in London, who tried many experiments with it, and declared they thought it as good oil of Cloves as they had seen.

As there is so great an affinity between this tree and the true Clove, it might be worthy of trial, if the fruit when first formed, or the flowers were beaten down from the trees, and dried in the same manner as the eastern Cloves, might not answer the same purpose; or, at least, it would be a good succedaneum for that spice; and as it is the production of our own colonies, should have proper encouragement.

This tree is propagated by seeds, which in the natural place of its growth is conveyed, and sown by birds, to a great distance; and, it is very probable, the seeds passing through them, are rendered fitter for vegetation, than those which are immediately gathered from the tree; for I have received great quantities of the berries from the gentleman before-mentioned, which were perfectly ripe and fresh, great part of which I sowed in different ways, and communicated some of them to several other curious persons, who did the same, but none of them have yet succeeded; and upon informing my friend Mr. Williams of this, he told me that a friend of his, whose plantation was on the south side of Jamaica, desired him to save a large quantity of the ripe berries for him to sow on his plantation, which he accordingly did, but his friend forgot to send for them till near two years after; during which time, they had lain in a large heap, and had fermented, and, on sowing those berries, the plants came up with the first rains in great abundance; so that it may be of great service to these seeds, either to pass through animal bodies, or to be fermented before they are sown.

The plants cannot be preserved in England unless they are placed in a stove during the winter season, but they will thrive in a moderate degree of warmth: they should be planted in a soft light soil, and in winter must have but little water. In the summer they should have a large share of air, and in July, if the season proves warm, they may be placed in the open air, in a warm sheltered situation; but upon the approach of cold nights, they must be removed into the stove again. The exposing of these plants to the open air for one month only, will be of great service to clean their leaves from insects or filth, which they are subject to contract, by remaining long in the

stove; but if the season should prove very wet or cold, it will not be safe to trust these plants long abroad; therefore their leaves should be now and then washed with a sponge to clean them, which will not only render them more sightly, but also promote their growth. This tree is pretty difficult to propagate in England, where the seeds do not ripen; the only method in which this has been done, is by laying down the young branches, sitting them at a joint in the same manner as is practised in making layers of Carnations. If this is carefully performed, and the layers are regularly but gently watered, they will put out roots in one year; then they may be carefully separated from the old plants, and each planted in a small pot filled with light earth, and plunged into the tan-bed, either in the stove or under a frame, being careful to shade them until they have taken new root, after which they may be treated as the older plants. This plant, being an Evergreen, makes a fine appearance in the stove at all seasons of the year; and their leaves having such an agreeable fragrantcy when rubbed, render them as worthy of a place in the stove, as any other tender exotic plant which is preserved for ornament.

The third sort grows naturally in Jamaica, from whence I received it some years past. This rises with a divided trunk to the height of eight or ten feet, sending out many branches, which are placed opposite, covered with a grey bark: the leaves come out opposite, which are shorter and rounder at their points than those of the last species; they are also smoother, and of a firmer texture. The flowers come out from the side of the branches between the leaves, upon slender foot-stalks, about an inch in length, two generally arising from the same point: these are succeeded by round berries, of a brighter colour than those of the former, having the empalement on their crowns. The leaves and fruit of this sort have no aromatic flavour, so are not of use, but the characters of the flower and fruit are the same as in the other sort.

This tree retains its leaves all the year, which being of a splendent green, make a very good appearance, when it is intermixed with other exotic plants in the stove; but the flowers being small, and growing thinly upon the branches, do not make any great figure, so it is only preserved for the beauty of its foliage. It is propagated by seeds, and requires the same treatment as the other sort.

The fourth sort was sent me by the late Mr. Robert Millar, surgeon, from Carthage in New Spain: this rises with many irregular stems about twelve or fourteen feet high, covered with an Ash-coloured bark, dividing into many branches upward: these are garnished with stiff oval leaves, placed opposite. The flowers are produced from the side of the branches, sometimes four, five, or six foot-stalks arise from the same point; at other times, they come out single, or perhaps by pairs: these are white, and of the same shape with those of the second sort, and are succeeded by berries which are rounder, and, for the most part, contain but one kidney-shaped seed.

This sort agrees with the second in its general characters, but not in the virtues, for it hath none of the aromatic flavour, with which that abounds; but as it retains its leaves through the year, may merit a place in the stove, better than many other plants which are preserved by the curious. This is propagated by seeds, in the same way as the second sort, and the plants must be treated in the same manner as those.

The fifth sort was sent me from the island of Barbuda, where it rises to the height of twenty feet; the trunk and branches are covered with a smooth brown bark. The branches come out by pairs; they grow erect, and are garnished with very stiff, smooth, lucid leaves, which are placed opposite, and have very short foot-stalks. The leaves vary much in their form; some of them are oval, others oblong, and some are indented so deeply at their ends, as to

be almost heart-shaped. Their consistence is much thicker than those of the common Laurel, and their colour is a splendid green, with one deep midrib running through their middle, and many small veins going from thence transversely to their border. The flowers are produced in small loose bunches at the extremity of the branches, which have several narrow leaves intermixed with the bunches. These are succeeded by berries of the same shape with those of the second sort, but larger.

This tree is propagated by seeds as the other species, and deserves a place in the stove, for the beauty of its evergreen leaves, which being of a thick consistence, and of a shining green colour, make a fine appearance in the stove at all seasons of the year; but this hath no aromatic flavour to recommend it, as hath the second sort, for which reason it is seldom noticed. I take this to be the Bay-tree, mentioned by Hughes, in the History of Barbadoes, which he describes to have no flavour; for I have seen plants of this sort which were brought from Barbadoes, so that I suppose it grows naturally there.

As the plants of these sorts do not rise so readily from seeds in England, the best way to obtain them, is to get some person of skill in America, to take up a number of young plants, and plant them close in boxes of earth, setting them in the shade till they have taken new root; then remove them into an open situation, where they may have time to establish their roots before they are shipped for England; and in their passage they must be guarded from the spray of the sea, and salt water, and should have very little water given them; for most of the plants which are sent to England, are killed in their passage by having too much wet. If these directions are observed, the plants may be brought in good health to England, provided they come over any time in the summer, that they may have time to get fresh root before the cold season begins; and when once they are well established in their roots here, they may be preserved many years in vigour; but I have not seen many of the plants in flower here as yet.

CASSIA. See OSYRIS.

CASSIA. Lin. Gen. Plant. 461. Cassia, or Wild Senna.

The CHARACTERS are,

The empalement is composed of five concave coloured leaves; the flower hath five roundish concave petals, which spread open: it hath ten declining stamina, three of the lower are long, the three upper are shorter; the summits of the three lower are large, arched, beaked, and separated at their points; the three upper stamina have very small summits; the four side stamina have no beaks, but spread from the other. In the center is situated a long taper germen, having a short style, terminated by an obtuse stigma. The germen afterward becomes a long pod, divided by transverse partitions, each containing one or two roundish seeds, fastened to the margin of the upper valve.

This genus of plants is ranged in the first section of Linnaeus's tenth class, intitled Decandria Monogynia, the flowers having ten stamina and one style.

The SPECIES are,

1. CASSIA (*Occidentalis*) foliis quinquejugis, ovato-lanceolatis, margine scabris, exterioribus majoribus, glandula bascos petiolorum. Lin. Sp. Plant. 337. Cassia with leaves composed of five pair of oval spear-shaped lobes with rough borders, the upper lobes being the largest, and a small gland at the base of the foot-stalk. Senna occidentalis, odore opii viroso, orobi Pannonici foliis mucronatis glabris. Hort. Amst. 1. p. 51. tab. 26.
2. CASSIA (*Frutescens*) foliis quinquejugatis ovatis glabris, exterioribus longioribus, caule fruticoso. Cassia with leaves composed of five pair of smooth oval lobes, the upper being the longest, and a shrubby stalk. Senna spuria Americana frutescens, foliis mucronatis minoribus, siliquis teretibus, duplici seminum ordine factus. Houst. MSS.
3. CASSIA (*Alata*) foliolis octojugatis, ovali-oblongis, interioribus minoribus, petiolis eglandulosis stipulis

patulis. Hort. Cliff. 158. Cassia with eight pair of oblong oval lobes, the inner being the least, foot-stalks without glands, and a spreading stipula. Cassia sylvestris foetida, siliquis alatis. Plum. Cat. 18. Wild stinking Cassia with winged pods.

4. CASSIA (*Villosa*) foliolis trijugatis, oblongo-ovatis aequalibus villosis, siliquis articulatis, caule erecto arboreo. Cassia with three pair of oblong, oval, hairy leaves, which are equal, jointed pods, and an upright woody stem. Senna spuria arborea, villosa, foliis latis mucronatis, siliquis articulatis. Houst. MSS.
5. CASSIA (*Uniflora*) foliolis trijugatis, ovato-acuminatis, villosis, floribus solitariis axillaribus, siliquis erectis. Cassia with three pair of lobes in each leaf, which are oval, pointed, hairy, and single flowers proceeding from the sides of the stalks, with upright pods. Senna spuria herbacea orobi Pannonici foliis rotundioribus, flore parvo, siliquis erectis. Houst. MSS.
6. CASSIA (*Marylandica*) foliis octojugis ovato-oblongis, aequalibus, glandula bascos petiolorum. Lin. Sp. 541. Cassia with small leaves composed of eight pair of oblong, oval, equal lobes, having a gland at the base of the foot-stalk. Cassia Marylandica pinnis foliorum oblongis, calyce floris reflexo. Mart. Cent. 1. 21.
7. CASSIA (*Bicapsulari*) foliolis trijugatis, obovatis glabris, interioribus rotundioribus minoribus, glandula interjecta globosa. Hort. Cliff. 159. Cassia with three pair of oval smooth leaves, the inner ones being rounder, smaller, and a globular gland placed between the leaves. Cassia hexaphylla, siliqua bicapsulari. Plum. Cat. 18.
8. CASSIA (*Fistula*) foliis quinquejugatis ovatis acuminatis, petiolis eglandulosis. Flor. Zeyl. 149. Cassia with five pair of oval, pointed, smooth lobes, and foot-stalks having no glands. Cassia fistula Alexandrina. C. B. P. 405. The purging Cassia of Alexandria, or Pudding Pipe-tree.
9. CASSIA (*Bahamensis*) foliolis sexjugatis, lanceolatis, glabris, interioribus minoribus, floribus terminatricibus. Cassia with six pair of smooth spear-shaped lobes, the inner ones being smaller, and flowers terminating the stalk. Cassia Bahamensis, pinnis foliorum mucronatis angustis, calyce floris non reflexo. Martyn. Cent. 1. p. 21.
10. CASSIA (*Fruticosa*) foliolis bijugatis, ovato-lanceolatis, glabris, floribus terminalibus, siliquis longis teretibus, caule fruticoso. Cassia with two pair of oval, spear-shaped, smooth lobes, flowers terminating the stalks, long taper pods, and a shrubby stalk. Cassia fruticosa tetraphylla, siliquis erectis. Houst. MSS.
11. CASSIA (*Javanica*) foliolis duodecemjugatis, oblongis, obtusis, glabris, glandula nulla. Lin. Sp. Plant. 379. Cassia with twelve pair of smooth lobes, which have no glands. Cassia fistula Brasiliana. C. B. P. 403. Purging Cassia of Brazil, commonly called Horse Cassia in America.
12. CASSIA (*Lignstrina*) foliolis septemjugatis, oblongo-ovatis, floribus spicatis axillaribus, siliquis recurvis. Cassia with seven pair of oblong oval lobes, and short spikes of flowers proceeding from the sides of the stalks, and recurved pods. Senna folio ligustri. Plum. Cat. 18. Senna with a Privet leaf.
13. CASSIA (*Emarginata*) foliolis trijugatis, obtusis, emarginatis, caulibus pilosis, floribus solitariis axillaribus petiolis longioribus. Cassia with three pair of obtuse leaves, indented at the top, hairy stalks; flowers growing singly from the sides of the stalks upon a long foot-stalk. Senna spuria frutescens, foliorum pinnis latioribus, caulibus pilosis, siliquis longissimis pediculis infidentibus. Houst. MSS.
14. CASSIA (*Biflora*) foliolis quadrijugatis oblongo-ovatis, caulibus procumbentibus, floribus axillaribus pedunculis bifloris. Cassia with four pair of oval oblong leaves, trailing stalks, and flowers proceeding from the sides of the stalks, two growing upon each foot-stalk. Senna spuria minima, procumbens, foliorum pinnis subrotundis, caule pubescente. Houst. MSS.
15. CASSIA (*Arborecens*) foliolis bijugatis oblongo-ovatis, subtus villosis, floribus corymbosis, caule erecto arboreo. Cassia with two pair of oblong oval leaves, hairy on their under side, flowers growing in round bunches, and an erect tree-like stem. Senna spuria tetra-

tetraphylla arborea, filiquis compressis, angustis, longissimis, pendulis. Houst. MSS.

16. CASSIA (*Flexuosa*) foliolis multijugatis linearibus, floribus solitariis axillaribus, pedunculis longissimis. *Cassia with many pair of narrow leaves, single flowers proceeding from the sides of the stalks, and very long foot-stalks.* Senna occidentalis, foliis herbæ mimosæ, filiquâ singulari, floribus pediculis longioribus insistentibus. Sloan. Hist. Jam. 2. 51.

17. CASSIA (*Chamæcris*) foliolis multijugatis linearibus, caulibus procumbentibus, frutescentibus, floribus maximis solitariis axillaribus, filiquis glabris. *Cassia with many pair of small leaves, which are narrow, shrubby trailing stalks, large flowers growing singly from the sides of the stalks, and smooth pods.* Senna spuria mimosæ foliis, frutescens & procumbens, flore maximo, filiquis glabris. Houst. MSS.

18. CASSIA (*Pentagonia*) foliolis trijugatis ovatis, exterioribus majoribus glandulâ subulatâ inter inferiora. Prod. Leyd. 46. *Cassia with three pair of small oval leaves, the upper being the largest, and an owl-shaped glandule between the lower pair.* Senna spuria plerumque hexaphylla filiquâ pentagonâ alatâ. Houst. MSS.

19. CASSIA (*Racemosa*) foliolis quinquejugatis, lanceolatis rigidis floribus racemosis axillaribus, filiquis planis, caule fruticoso. *Cassia with five pair of spear-shaped stiff leaves, flowers growing in bunches from the sides of the stalk, flat pods, and a shrubby stalk.*

20. CASSIA (*Procumbens*) foliolis bijugatis ovatis, caulibus procumbentibus, floribus solitariis axillaribus, filiquis hirsutis. *Cassia with two pair of small oval leaves, trailing stalks, single flowers proceeding from the sides of the stalk, and hairy pods.* Senna spuria tetraphylla herbacea procumbens, filiquis hirsutis. Houst. MSS.

21. CASSIA (*Glandulosa*) foliolis multijugatis, glandulâ petioli pedicellatâ, stipulis ensiformibus. Hort. Upsal. 101. *Cassia with many pair of leaves, and the gland on the foot-stalk resembling an insect, and sword-shaped stipule.* Chamæchrista pavonis Americana, filiquâ multiplici. Breyn. Cent. 64.

The first sort grows naturally in most of the islands in the West Indies, where it is called Stinking Weed, from its unfavoury odour. This rises with a channelled stalk three or four feet high, dividing into several branches, garnished with winged leaves placed alternately; each of these is composed of five pair of lobes which are oval, spear-shaped, sitting close to the midrib, having rough edges, the lower pair of lobes being the smallest, the others enlarge to the top, which are the biggest; at the base of the foot-stalk is produced a small protuberance, which is called a gland; this is differently situated in the several species of this genus. The flowers come out from the sides of the stalks, two growing upon each foot-stalk; but the branches are terminated by loose spikes of flowers, which are composed of five concave yellow petals, with ten declining stamina, situated round the germen and style, which becomes a sword-shaped flat pod, having a border on each side, and is indented between each seed.

This is a biennial plant, which is propagated by seed in plenty, in the countries where it grows naturally; but in England, the seeds must be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a separate pot, filled with light earth, and plunged into a moderate hot-bed, where they should be shaded till they have taken fresh root; after which they should have fresh air admitted to them every day, in proportion to the warmth of the season, and should be frequently watered. When the plants have filled the pots with their roots, they should be shifted into larger; and if they are too tall to remain in the hot-bed, they must be placed either in the stove, or a glass-case, where they may be defended from cold, but in warm weather have plenty of air. With this management the plants will flower in August, and perfect their seeds in October, but may be preserved through the winter in a stove, where they will continue flowering a long time. In

warm summers the plants may be placed in the open air toward the latter end of June, where they will flower very well; but these will not perfect their seeds, unless they are removed into the stove in autumn.

The second sort was sent me from Jamaica by the late Dr. Houstoun, who found it growing there naturally. This rises with a shrubby stalk five or six feet high, sending out many branches toward the top, garnished with winged leaves, composed of five pair of small oval leaves, the upper ones being longest. The flowers come out from the side of the stalks, and also terminate the branches in loose spikes; these are yellow, and shaped like those of the former, but are smaller; the pods are long, taper, and contain two rows of seeds.

This plant may be preserved three or four years in the stove, and will annually flower and perfect the seeds. It is propagated by seeds, which should be sown on a hot-bed in the spring; and the plants must be treated in the same manner as the former sort, with only this difference, that these, when they are too tall to remain longer under the frames on the hot-bed, must be removed into the stove, where they will often flower in autumn or winter, but they seldom perfect their seeds till the second year.

The third sort hath an herbaceous stalk, which rises five or six feet high, garnished with long winged leaves, composed of eight or ten pair of large oval lobes, each being more than three inches long, and one broad, rounded at the end, where they are slightly indented. The flowers are produced in loose spikes at the top of the stalk, which are large, yellow, and of the same shape with those of the other species; the pods are long, taper, and have four borders or wings running longitudinally; these contain a double row of angular seeds. The whole plant hath a strong foetid odour.

This sort seldom continues more than two years; it must be raised from seeds as the former sorts, and placed in the tan-bed in the stove, being very tender, and should have but little water in winter. The second year the plants will flower, but they very rarely produce seeds in England.

The fourth sort was sent me from Campeachy by the late Dr. Houstoun, who found it growing there in great plenty. This rises with a woody stem to the height of fourteen or sixteen feet, sending out many lateral branches, garnished with winged leaves, composed of three pair of oblong, oval, hairy lobes, of equal size; the flowers come out in loose bunches at the end of the branches, which are of a pale straw colour, and small, but shaped like the others; the pods are long, narrow, and jointed, each seed being lodged in a sort of isthmus; the seeds are oval and brown.

This may be propagated by seeds, which must be sown upon a hot-bed, and the plants afterward treated as the former sorts, placing them in a warm stove, where they will continue several years producing their flowers in summer, and in warm seasons the seeds will ripen.

The fifth sort is a low herbaceous plant, seldom rising a foot high; the stalk is single, and garnished with winged leaves, composed of three pair of oval pointed lobes, which are hairy; the flowers come out single from the side of the stalks; they are of a pale yellow, and small; these are succeeded by narrow taper pods two inches long, which grow upright. This plant is annual; the seeds must be sown on a hot-bed, and the plants treated as the first sort: they will flower in July, and ripen their seeds in autumn. This was sent me from Campeachy by the late Dr. Houstoun.

The sixth sort grows naturally in Maryland, from whence I received the seeds. It hath a perennial root, composed of a great number of black fibres; this sends out several upright stalks in the spring, which rise four or five feet high, garnished with winged leaves, composed of nine pair of oblong smooth lobes, which are equal; toward the upper part of the stalks

the

the flowers come out from the wings of the leaves, two or three together; but the stalks are terminated by loose spikes of pale yellow flowers, which are rarely succeeded by pods in England. The stalks decay in autumn, and rise again in the spring. The roots of this sort continue many years, and will live abroad in a warm border and a dry soil. The seeds will come up in the full ground, if sown in April, and in autumn they may be planted into the borders where they are designed to remain.

The seventh sort is an annual plant, which rises a foot and a half high, with an erect herbaceous stalk, garnished with winged leaves, composed of three pair of oval lobes; the flowers come out singly from the wings of the leaves; these are small, yellow, and of the same shape with those of the other species, and are succeeded by taper pods, having cells containing two rows of seeds. It grows naturally in Jamaica, and the other sugar islands.

This is propagated by seeds, which must be sown on a hot-bed in the spring, and the plants afterward treated in the same manner as hath been directed for the first sort. They flower in July, and the seeds ripen in October, and then the plants will decay.

The eighth sort is the tree which produces the purging Cassia which is used in medicine. It grows naturally in Alexandria, and in both Indies, where it rises to the height of forty or fifty feet, with a large trunk, dividing into many branches, garnished with winged leaves, composed of five pair of spear-shaped lobes, which are smooth, having many transverse nerves from the midrib to the borders; the midrib is very prominent on the under side; the flowers are produced in long spikes at the end of the branches, each standing upon a pretty long foot-stalk; these are composed of five large concave petals, of a deep yellow colour, and are succeeded by cylindrical pods, which are from one to two feet long, with a dark brown woody shell, having a longitudinal seam on one side, divided into many cells by transverse partitions, each containing one or two oval, smooth, compressed seeds, lodged in a sweetish black pulp, which is the part used in medicine.

This tree is propagated by seeds, which may be easily procured from the druggists who import the pods for use; these must be sown on a hot-bed in the spring, and when the plants come up, they must be treated in the same manner as the first sort, during the first summer; and in autumn they must be removed into a stove, and plunged into the tan-bed: during the winter they should have very little water; for as these trees grow naturally in dry sandy land, moisture is a great enemy to them, but especially during that season. In the summer they should have a good share of air admitted to them in warm weather, but they will not thrive in the open air in this country, at the warmest time of the year, so should constantly remain in the stove. With proper care these plants will grow to the height of eight or ten feet, and produce their flowers, when they make a fine appearance.

The ninth sort grows naturally in the Bahama Islands, from whence I received the seeds. This is an annual plant, which rises with an upright stalk two feet and a half high, garnished with winged leaves, composed of six pair of lobes, which are smooth, narrow, and spear-shaped, standing at wide distances; the flowers are collected into loose bunches at the top of the stalks, which are of a pale yellow, and are succeeded by long compressed pods. It flowers in July, and the seeds ripen in autumn. This must be treated as the first sort.

The tenth sort was sent me from La Vera Cruz, in New Spain, by the late Dr. Houstoun. This grows upward of twenty feet high, with several trunks covered with brown bark; these divide into many branches upward, garnished with winged leaves, composed of two pair of lobes, which in the lower leaves are oval; but those of the upper are five inches long, and two and a half broad in the middle, smooth, and of a light green. The flowers are produced in

loose spikes at the extremity of the branches, which are large, of a gold colour, and succeeded by taper brown pods about nine inches long, having many transverse partitions, in which the seeds are lodged in a thin pulp.

This sort is propagated by seeds, which must be sown upon a hot-bed, and the plants afterward treated in the same manner as the eighth sort, for the plants will not live abroad in this country in the warmest season of the year; but if properly managed in the stove, will produce their beautiful flowers in three or four years from the seed.

The eleventh sort grows in great plenty in most of the islands of the West Indies. This rises to a great magnitude, with a large trunk, dividing into many branches, garnished with very long winged leaves, composed of twelve or fourteen pair of oblong blunt lobes, which are smooth, of a light green, and placed near together. The flowers come out in loose spikes at the end of the branches, which are of a pale Carnation colour, shaped like those of the other species, and are succeeded by large cylindrical pods, divided by transverse partitions into many cells, in which the seeds are lodged, surrounded with a black purging pulp. This is called Horse Cassia, because it is generally given to horses, and seldom taken by any persons on account of its griping quality.

It is propagated by seeds, which should be sown, and the plants afterward treated in the same manner as the eighth sort, with which management they will thrive and produce flowers in England.

The twelfth sort was sent me from the Havannah by the late Dr. Houstoun. This hath an herbaceous stalk, which divides into many branches, rising about three feet high, garnished with winged leaves, composed of seven pair of oblong oval lobes, which are rounded at the end. The flowers come out from the side of the branches, upon very long foot-stalks, disposed in loose spikes; these are of a pale yellow, and are succeeded by recurved pods, containing one row of compressed seeds.

This is a biennial plant, which, if brought forward early in the spring, will sometimes perfect seeds the same year; but if they should fail, the plants may be kept through the winter in a stove, as the first sort, and good seeds may be obtained the following season.

The thirteenth sort rises with several weak shrubby stalks about two feet high, closely garnished with winged leaves, composed of three pair of lobes, which are very narrow at their base, enlarging to the top, where they are blunt, and rounded with a little indenture at the point; these contract closely every evening, after the sun has left them. The flowers come out single from the side of the branches, standing upon very long foot-stalks; they are of a bright yellow, and shaped like those of the other species, and are succeeded by narrow flat pods, an inch and a half long. This grows plentifully in Jamaica. It is propagated by seeds, which must be sown on a hot-bed, and managed as the other tender sorts; it will continue two or three years, if placed in a warm stove.

The fourteenth sort sends out from the root two or three slender stalks, which trail on the ground, garnished with winged leaves, having four pair of small roundish lobes, of a pale green; at the insertion of the foot-stalks arise those of the flower, which is jointed, dividing into two shorter at the top, sustaining two small yellow flowers. This grows naturally in Jamaica, from whence the seeds were sent me. It is an annual plant, whose seeds must be sown early in the spring on a hot-bed, and treated like the other kinds; but as the branches of this grow near the ground, so the plants may remain under a frame all the summer, and will flower in July; when, if the season is warm, they must have a large share of air, otherwise the flowers will fall off, without being succeeded by pods; but if rightly managed, the seeds will ripen in autumn.

The

The fifteenth sort was sent me from La Vera Cruz, in New Spain, by the late Dr. Houstoun. This rises with a strong upright trunk, to the height of twenty-five, or thirty feet, dividing into many branches, which are covered with an Ash-coloured bark, garnished with winged leaves, having long foot-stalks; each being composed of two pair of oblong oval lobes, four inches long, and near two broad, which are smooth, of a dark green on their upper side, but paler underneath. The flowers are produced sometimes from the side of the stalks, where they are few and scattering, but the ends of the branches have large round bunches of flowers, which branch out from one center; they are of a deep yellow, inclining to an Orange colour. These are succeeded by compressed pods, near nine inches long, having a border on each side, and contain one row of oval, smooth, compressed seeds.

This sort may be propagated by seeds, which should be sown on a hot-bed in the spring, and when the plants come up, they will require the same treatment as the seventh sort; with which management the plants will thrive, and produce their flowers in a few years.

The sixteenth sort hath very slender trailing stalks, about two feet long, garnished with winged leaves, sitting close to the branches, composed of many narrow pinnæ, like those of the Sensitive Plant; the flowers come out single from the side of the stalk, upon long slender foot-stalks, which are small, of a bright yellow colour, shaped like those of the other species; they are succeeded by short flat pods, containing two or three seeds. This grows naturally in Jamaica. It is a biennial plant, and requires the same treatment as the first sort.

The seventeenth sort was sent me by the late Dr. Houstoun from La Vera Cruz, where he found it growing naturally. This rises with several shrubby trailing stalks, which are two feet long, sending out many side branches, closely garnished with winged leaves, composed of several pair of very narrow pinnæ, smaller than those of the sensitive Plant. The flowers are produced single from the side of the branches, on very short foot-stalks; they are large, of a deep Orange colour, and are succeeded by short, narrow, smooth pods. This plant differs much from the *Chamæ crista pavonis major*, of Breynius, in having a shrubby trailing stalk; the leaves are much shorter, having but half the number of pinnæ, which are also narrower and shorter, the flower is also larger.

This plant will continue two or three years, and produce flowers annually, but it must be treated in the same manner as the other tender sorts; for it will not thrive unless it is preserved in a warm stove, where it will perfect seeds the second year. It flowers in July and August, and the seeds ripen in autumn.

The eighteenth sort was sent me from Campeachy, by the late Dr. Houstoun. This rises with a shrubby slender stalk about two feet high, dividing upward into several branches, which are thinly garnished with winged leaves, composed of three pair of oval lobes, the upper being the largest; these stand upon long foot-stalks, from the base of which comes out the flower, standing single on a short foot-stalk, of a pale yellow colour, and is succeeded by a bending pod, near four inches long, having five longitudinal wings, ending in a point.

It is a biennial plant, which if brought forward in the spring, will flower the same summer, and sometimes perfect seeds in autumn; but if the plants are placed in a warm stove, they will live through the winter, and the following season will flower earlier, and good seeds may then be obtained.

The nineteenth sort rises with a shrubby stalk to the height of ten or twelve feet, dividing upward into many branches, garnished with winged leaves, composed of five pair of stiff spear-shaped lobes; the flowers come out from the side of the branches, on long branching foot-stalks, collected into large loose

spikes; these are of a deep Orange colour, large, and shaped like those of the other species, and are succeeded by flat brown pods, about four inches long, containing one row of flat, smooth, oval seeds. This sort was sent me from Carthagera, by the late Mr. Robert Millar.

This sort is propagated by seeds in the same manner as the other species, and requires a warm stove to preserve it, where it will thrive and produce flowers annually.

The twentieth sort was sent me from La Vera Cruz, by the late Dr. Houstoun. This hath several trailing herbaceous stalks, about two feet long, garnished with winged leaves, having long foot-stalks, which are placed at a considerable distance from each other; they have two pair of oval smooth lobes. The flowers come out single from the side of the branches, which are of a pale yellow colour, and are succeeded by short, flat, hairy pods, containing one row of flat seeds.

This is an annual plant, which must be raised on a hot-bed early in the spring, and treated in the same manner as the other annual sorts before-mentioned. It flowers in July, and the seeds ripen in autumn.

The twenty-first sort grows common in all the islands of the West-Indies. This rises with a slender stalk about two feet high, sending out a few side branches upward, garnished with winged leaves, composed of many pairs of narrow pinnæ, like those of the Sensitive Plant. The flowers come out upon short foot-stalks from the side of the branches, each foot-stalk sustaining two or three yellow flowers, of the same form with the other species of this genus; these are succeeded by short flat pods, containing three or four flat seeds in each.

This is an annual plant, and requires the same treatment as the last; but as the stalks of this grow upright, they will be too tall to remain under a frame all the summer; therefore when the plants are advanced so high as to be near the glasses, they should be removed into the stove, or a glass case, where they may have room to grow, and be screened from the cold, but in warm weather should have a good share of air admitted to them; with this management they will flower in July, and perfect their seeds in autumn.

These plants are frequently preserved in the gardens of several curious persons, therefore I have enumerated them here, though several of them have not much beauty to recommend them, but are chiefly kept for the sake of variety. The most beautiful are the fourth, the eighth, tenth, eleventh, fifteenth, and nineteenth sorts; these all make a good appearance in the stove, especially when they are in flower; and as they retain their leaves all the year, they make an agreeable variety in the winter season, when intermixed with other plants from the same countries. All the species of this genus contract their leaves every evening as the sun declines, and open them again with the rising sun in the morning; which is also common to many other plants, some of which turn their upper surface outward, but all those of this genus turn their under surface outward, the upper being very closely folded together. These are what Linnæus titles sleeping plants. It must also be observed that most of those plants, whose under surface is turned outward, are such as grow upon dry sandy land, where their roots do not find a supply of moisture, so that the lower surface of their leaves being generally covered with a short soft down, or hairs, detain the nightly dews, which are inhaled by the leaves, and furnish part of their nourishment; whereas the other, whose upper surface is turned outward, do not stand in need of this supply; being smooth, the moisture is cast off, and not imbibed by them.

CASSIDA [i. e. an helmet,] Scull-cap. See SCUTELLARIA.

CASSINE. Lin. Gen. Plant. 333. The Cassiberry Bush, and South-Sea Thea.

E e e

The

The CHARACTERS are,

It hath a small permanent empalement, which is divided into five parts; the flower hath but one petal, which is cut into five obtuse segments, which spread open; it hath five stamina, which spread from each other, and are terminated by single summits; it hath a conical germen, without a style, supporting three reflexed stigma. The germen afterward becomes an umbilicated berry with three cells, each containing a single seed.

This genus of plants is ranged in the third section of Linnæus's fifth class, intitled, Pentandria Trigynia, the flower having five stamina, and three stigma.

The SPECIES are,

1. CASSINE (*Corymbosa*) foliis ovato-lanceolatis, serratis, oppositis, floribus corymbosis axillaribus. Fig. Pl. plat. 83. f. 1. *Cassine with oval spear-shaped leaves placed opposite, and flowers growing in round bunches from the sides of the branches.* Cassine vera perquam similis, arbutula, Phillyrea foliis antagonists, ex Provincia Carolinensi. Pluk. Mant. 40. *The Cassioberry Bush.*
2. CASSINE (*Paragua*) foliis lanceolatis alternis semper-virentibus, floribus axillaribus. Fig. pl. Plat. 83. f. 2. *Cassine with evergreen spear-shaped leaves placed alternately, and flowers proceeding from the sides of the branches.* Cassine vera Floridanorum, arbutula baciferâ, Alaterni forme facie, foliis alternatim sitis tetrapylene. Pluk. Mant. 40. *Evergreen Cassine, Yapon, or South-Sea Tea.*
3. CASSINE (*Oppositifolia*) foliis ovatis acutis glabris, floribus axillaribus sparsis. *Cassine with oval acute leaves placed opposite, and flowers coming from the wings of the stalks, commonly called Hysson Tea.*

The first sort rises with two or three stems, which send out many side branches their whole length, and become bushy; these seldom rise more than eight or nine feet high. The branches are garnished with oval spear-shaped leaves, sawed on their edges, which grow opposite. Toward the upper part of the branches the flowers come out from the sides, growing in roundish bunches; these are white, and are divided into five parts almost to the bottom; in their center is placed the germen, attended by five stamina, which spread open, near as much as the segments of the petal. After the flower is past, the germen swells to a round berry, having three cells, each containing a single seed. This is by Dr. Linnæus supposed to be the same plant as the Phillyrea Capensis folio celastri. Hort. Elth. But those who know both the plants, can have no doubt of their being different. The Cassine here mentioned drops its leaves in autumn, whereas that Phillyrea is evergreen; the former lives abroad in the open air, but the latter can scarce be kept through the winter in a green-house, without artificial heat; nor have the plants the same appearance, and withal differ essentially, according to his own system, in the number of stamina, which removes them to different classes.

The first sort has been pretty common in the nurseries near London some years, where it is propagated by laying down the branches, which afford shoots in plenty for that purpose from the root, and lower part of the stem, so as to become very bushy and thick, if they are not cut off; there are numbers of these shrubs which produce flowers in England every year, but none of them ripen their seeds.

The leaves of this plant are extremely bitter, so that if a single one is chewed, the bitterness cannot be gotten rid of in a long time. These leaves will continue green very late in autumn, if the season proves mild, and they come out early in the spring, but are frequently pinched by the frost in March, when they appear so soon. This shrub flowers in July and August. It grows naturally in Virginia and Carolina.

It loves a light soil, not too dry, and should have a warm situation; for, in exposed places, the young shoots are frequently killed in the winter, whereby the shrubs are rendered unsightly; but where they are

near the shelter of trees, or walls, they are very rarely hurt.

The second sort grows naturally in Carolina, and also in some warm parts of Virginia, but chiefly near the sea; this, in the natural places of its growth, rises to the height of ten or twelve feet, sending out branches from the ground upward, which form themselves into a sort of pyramid, garnished with spear-shaped leaves, placed alternately; these are in texture and colour like those of Alaternus, and continue green through the year. The flowers are produced in close whorls round the branches, at the foot-stalks of the leaves; they are white, and of the same shape as the former; these are succeeded by red berries, like those of the former sort.

Dr. Linnæus has separated this from the class in which he has placed the other, and has joined it to the Dahoon Holly, supposing them to be the same plant; in which he is equally mistaken, for they not only differ in the shape of their leaves, but also in their essential characters; for the Dahoon Holly must, according to his system, be ranged in his twenty-second class, and the Cassine must be ranged in his fifth.

This plant was many years preserved in several curious gardens near London, till the severe winter in 1739, when most of them were destroyed, so that there was scarce any left; but of late years there have been many of the young plants raised from seeds, which came from Carolina, some of which have been growing in the full ground several years, and have resisted the cold of the winters, without covering; though they often suffer in very cold seasons, where they are not very well sheltered. If this plant can be brought to thrive well in England, and to endure the winter in the open air, it will be a fine plant, to make a variety in plantations of Evergreen-trees. The leaves of this sort are not so bitter as those of the first, especially when green, therefore are preferred to them for making the Tea; but an infusion of the leaves of the first, has been taken for a loss of appetite by some persons with good success; but it must not be too strong, lest it should prove emetic or cathartic.

The inhabitants of North Carolina and Virginia, where this shrub grows in plenty, give it the title of Yapon, which I suppose to be the Indian name; for, as it is a plant much esteemed by the Indians for its medicinal virtues, they certainly have a name for it; this grows to the height of ten or twelve feet; the leaves are about the size and shape of those of the small leaved Alaternus, but are somewhat shorter, and a little broader at their base; they are a little notched about their edges, and are of a thick substance, and deep green colour; the flowers of this sort are produced at the joints near the foot-stalk of the leaves, but the Cassioberry Bush produces its flowers in umbels at the extremity of the shoots; the berries of this Yapon continue upon the plants most part of the winter, and, being of a bright red colour, intermixed with the green leaves, make a fine appearance at that season. From these berries continuing so long untouched by the birds, we may reasonably conclude, they have some venomous quality, because few of the fruits, or berries, which are wholesome, escape the birds, in a country where there are such flocks of many kinds of them.

These shrubs are propagated by sowing their seeds (which are obtained from Carolina, where they grow in great plenty near the sea-coasts;) they should be sown in pots filled with light sandy earth, and plunged into a gentle hot-bed, observing to water them frequently, until you see the plants appear, which is sometimes in five or six weeks time, and at other times they will remain in the ground until the second year; therefore, if the plants should not come up in two months time, you should remove the pots into a shady situation, where they may remain till October, being careful to keep them clean from weeds, and now and then in dry weather giving them a little

water;

water; then remove these pots into shelter during the winter season, and in the March following put them upon a fresh hot-bed, which will forward the seeds in their vegetation.

When the plants are come up, they should, by degrees, be exposed to the open air, in order to inure them to our climate; yet they should not be exposed to the open sun at first, but rather let them have the morning sun only, placing them for some time where they may be sheltered from cold winds; they should enjoy a shelter during the two or three first winters, after which the Cassioberry Bush may be planted abroad; but the South-Sea Thea should be kept in pots a year or two longer, being slower of growth, and will therefore not have strength enough to resist the cold when young.

The third sort has been but few years introduced to the English gardens; this rises eight or ten feet high, sending out branches from the root to the top, garnished with oval, smooth, entire leaves placed opposite, whose foot-stalks are drawn toward each other, whereby the leaves turn upward; the flowers come out from the wings of the leaves thinly, they are white, and of the same shape with those of the other sorts, but are not succeeded by berries in England.

This is propagated by seeds as the other sorts, or by laying down the branches in the spring, which if carefully performed will take root in one year; when they may be cut from the old plant, and put into small pots, and placed in the shade till they have taken new root; afterward they may be exposed in summer, but in autumn they must be removed into shelter.

The Paraguay, or South-Sea Thea, is accounted by the Indians very wholesome, and (as I have been informed by several worthy persons, who resided for several years in Carolina) is the only physic the Indians use; and for which, at certain times of the year, they come in droves, some hundred miles distant, for the leaves of this tree (it not being known to grow at any considerable distance from the sea;) where their usual custom is, to make a fire upon the ground, and, putting a great kettle of water thereon, they throw into it a large quantity of these leaves, and immediately set themselves round the fire, and, with a bowl that holds about a pint, they begin drinking large draughts, which in a very short time vomits them severely; thus they continue drinking and vomiting, for the space of two or three days, until they have sufficiently cleansed themselves; then they gather every one a bundle of the shrub to carry away with them, and retire to their habitations. But these gentlemen observed something very extraordinary in the operation of this plant, which was, that in vomiting it gave them no uneasiness, or pain, but came away in a full stream from their mouths, without so much as declining their heads, or the least reaching.

This plant is generally supposed to be the same as that which grows in Paraguay, where the jesuits of that country make a great revenue of the leaves, which they export to several other countries, where it is infused and drank like tea; indeed, there are some persons who doubt its being the same; which will be pretty difficult to determine, since there is so little converse between the inhabitants of Paraguay and those in Europe; and all the leaves of that tea, which have been brought to Europe, have been generally so broken and defaced, as to render it almost impossible to know their true figure; however, from some of the fairest leaves, which were picked out of the Paraguay Tea by a person of skill, who compared them with those of the Yapon, he had great reason to believe they were the same; and as the virtues attributed to the Yapon are nearly, if not absolutely, the same with those of the Paraguay, the Indians of these northern parts of America making the same use of it as the inhabitants of the south parts of America do, viz. to restore lost appetites, and they say it gives them courage and agility, for which purposes it has

been in use time out of mind: we may also observe, that the place of its growth in the north, is the same latitude as Paraguay is south; so I shall beg leave to insert the account given of the Paraguay Tea by Mons. Frezier, who travelled through great part of New Spain, by express order of the king of France.

In South Carolina the plant is called Cassena, or South-Sea Tea: the inhabitants of that country do not make so great use of this Tea, as those of Virginia and North Carolina; in the last of which, the white people have it in as great esteem as the Indians, and make as constant use of it.

Monsieur Frezier also says, that the Spaniards who live near the gold mines in Peru, are obliged frequently to drink of the herb Paraguay or Mate, to moisten their breasts, without which, they are liable to a sort of suffocation, from the strong exhalations which are continually coming from the mines.

The same author also adds, that the inhabitants of Lima, during the day-time, make much use of the herb Paraguay, which some call St. Bartholomew's Herb, who, they pretend, came into those provinces, where he made it wholesome and beneficial; whereas, before it was venomous; this, he says, is brought to Lima dry, and almost in powder.

Instead of drinking the tincture or infusion apart, as we drink tea, they put the herb into a cup or bowl made of a calabash tipped with silver, which they call mate; they add sugar, and pour the hot water upon it, which they drink immediately, without giving it time to infuse, because it turns black as ink. To avoid swallowing the herb, which swims at the top, they make use of a silver pipe, at the end whereof is a bowl full of little holes; so that the liquor sucked in at the other end, is clear from the herb. They drink round with the same pipe, pouring hot water on the same herb, as it is drunk off. Instead of a pipe, which they call bombilla, some part the herb with a silver separator, called apartador, full of little holes. The reluctance which the French have shewn to drink after all sorts of people, in a country where many have the venereal disease, has occasioned the inventing the use of little glass pipes, which they begin to use at Lima. This liquor, he says, in his opinion, is better than tea; it has a flavour of the herb, which is agreeable enough: the people of the country are so used to it, that even the poorest drink it once a day, when they rise in the morning.

The trade for this herb, (he says,) is carried on at Santa Fé, whether it is brought up the river of Plate. There are two sorts of it; the one called Yerba de Palos; and the other, which is finer, and of more virtue, Yerba de Camini; the last is brought from the lands belonging to the jesuits. The great consumption of it is between La Paz and Cusco, where it is worth half as much more as the other, which is sent from Potosi to La Paz. There come yearly from Paraguay into Peru about fifty thousand arrovas, twelve thousand hundred weight of both sorts, whereof at least one third is of the Camini, without reckoning twenty-five thousand arrovas of that of Palos for Chili. They pay for each parcel, containing six or seven arrovas, four royals for the duty called alcavala (being a rate upon all goods sold;) which, with the charge of carriage, being above six hundred leagues, doubles the first prices, which is about two pieces of eight; so that at Potosi it comes to about five pieces of eight the arrova. The carriage is commonly by carts, which carry an hundred and fifty arrovas from Santa Fé to Jujuy, the last town of the province of Tucuman; and from thence to Potosi, which is an hundred leagues farther, it is carried on mules.

What this curious author has observed, on there being two sorts of this herb, may very well agree with the two last sorts mentioned, since both of them are generally supposed to agree in their qualities, though one is much preferable to the other; therefore I imagine the Yerba de Camini, is what we call Paraguay or South-Sea Thea; and Yerba de Palos to be our

our third sort. But as our author only saw the dried herb, he could no more distinguish their difference, than we can the Thea brought from China; I mean, as to the particular trees which produce it.

CASSYTHA. Lin. Gen. Plant. 505.

The CHARACTERS are,

It hath a small three-leaved permanent empalement; the flower hath three petals which are concave and permanent, and three oblong, coloured, nectarious glands surrounding the germen, with nine erect compressed stamina, and two globular glands, inclosing each a single stamina, sitting on one side the base; these have summits under the top of the stamina; it has an oval germen within the coloured empalement, supporting a thick style the length of the stamina, crowned by an obtuse almost trifid stigma; the receptacle becomes a pulpy berry, globular but a little depressed, inclosed in the coloured empalement, having a perforated navel inclosing many oval seeds.

This is ranged in Linnæus's first order of his eleventh class of plants, intitled Enneandria Monogynia, the flower having eleven stamina and one style.

We have at present but one SPECIES of this genus.

CASSYTHA (*Filiformis*) Osb. It. Lin. 530. *Slender Cassytha*. *Cuscuta baccifera* Barbadosium. Pluk. Phyt. tab. 172. f. 2.

This plant grows naturally in both Indies. I have received it from Barbadoes, Jamaica, and the Spanish West Indies; and that it grows also in the East Indies, is plain from its figure in the Hortus Malabaricus. It rises with taper succulent stalks, which divide into many slender succulent branches; these come out frequently by threes or fours at the same joint, afterward they send out side branches singly without order, and become very bushy: the flowers come out on the side of the branches singly, sitting very close thereto, having no empalement; the corolla is oval, white, with a small tincture of red, opening like a navel at the top, including the germen, stamina, style, and nectarious glands so closely, as not to be discovered till the corolla is cut open; after the flower is past, the germen becomes many oblong, oval, dark seeds, surrounded with a mucilaginous substance.

This plant is easily propagated by planting cuttings of it during the summer months, but as these cuttings are succulent, it will be proper to cut them off a week before they are planted, laying them in the stove, that the part cut may have time to heal over before they are planted. These cuttings should be planted in small pots, which must be plunged into a moderate hot-bed, where, if they are not over watered, they will take root in six weeks; then they may be parted, planting each into a separate small pot, filled with light sandy earth, and may be plunged again into the hot-bed to forward their taking new root; after which they should be removed into a dry stove, where they should constantly remain, giving but little water in winter, and in summer admitting a large share of air in warm weather, for this plant is too tender to thrive in the open air in this climate.

CASTANEA. Tourn. Inst. R. H. 584. tab. 352. *Fagus*. Lin. Gen. Plant. 951. [It takes its name from Castana, a city of Thessaly, where this tree anciently grew in great plenty.] The Chestnut-tree, in French *Chateignier*, or *Maronnier*.

The CHARACTERS are,

It hath male and female flowers on the same tree, sometimes at separate distances, and at other times near each other. The male flowers are fixed to a long string, forming a sort of katkin; these have each an empalement of one leaf, cut into five parts; they have no petals, but include about ten or twelve bristly stamina, terminated by oblong summits. The female flowers have also an empalement of one leaf, divided into four parts, having no petals, but a germen fixed to the empalement, supports three styles crowned by a reflexed stigma. The germen, which is situated at the base of the empalement, becomes a roundish fruit armed with soft spines, including one or more nuts.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, intitled Monœcia Po-

lyandria; the plants of this section have male and female flowers, and the male flowers have many stamina; but he has joined this genus to the *Fagus*, making these of one genus, so that he has entirely abolished the title. However, as the male flowers of the Chestnut are formed into long katkins, and those of the Beech are globular; they may with propriety be kept separate; and this I choose to do, that it may be more intelligible to common readers.

The SPECIES are,

1. CASTANEA (*Sativa*) foliis lanceolatis acuminato-ser-ratis, subtus nudis. *Chestnut with spear-shaped leaves, which are sharply sawed, and naked on their under side*. *Castanea sativa*. C. B. P. 418. *The manured Chestnut*.

2. CASTANEA (*Pumila*) foliis lanceolato-ovatis acutè serratis, subtus tomentosis, amentis filiformibus nodosis. *Chestnut with oval spear-shaped leaves sharply sawed, which are woolly on their under side, and a slender knotted katkin*. *Castanea pumila* Virginiana, racemosa fructu parvo in singulis capsulis echinato unico. Pluk. Alm. 90. *The Chinquapin*.

3. CASTANEA (*Sloanea*) foliis oblongo-ovatis, serratis, fructu rotundo maximo echinato. *Chestnut with oblong, oval, sawed leaves, and a very large, round, prickly fruit*. *Sloanea amplis Castanæ foliis*. fructu echinato. Plum. Nov. Gen. 49.

The Chestnut is a tree which deserves our care, as much as any of the trees which are propagated in this country, either for use or beauty, being one of the best sort of timber, and affording a goodly shade. It will grow to a very great size, and spread its branches finely on every side where it has room. The leaves are large, of a lucid green, and continue late in the autumn; nor are they so liable to be eaten by insects, as are those of the Oak, which of late years have frequently happened to the latter, and has rendered them very unsightly great part of summer, which I have never observed to be the case with the Chestnut, which renders them more valuable for parks and plantations for ornament; and there is no better food for deer, and many other animals, than their nuts, which most of them prefer to acorns; but yet, there should not be many of these trees planted too near the habitation; because, when they are in flower, they emit a very disagreeable odour, which is very offensive to most people.

There are several varieties of this tree, which have accidentally arisen from seeds; some have been supposed distinct species, but the differences are only in the size of their fruit and leaves, which have been altered, and improved by culture; so that the wild and manured Chestnut, are undoubtedly the same; for I have frequently found, that the nuts taken from the same tree, and cultivated in the same soil, with equal care, have produced trees with very small fruit; and among them have been others, whose fruit have been as large as those of the parent tree; therefore they can be only esteemed as varieties. But in many countries, where the trees are cultivated for their fruit, the people graft the largest and fairest fruit, upon stocks of Chestnut raised from the nut; and these grafted trees are by the French called *Maronnier*, but they are unfit for timber.

There is also a Chestnut with variegated leaves, which is propagated in the nurseries by way of curiosity: this is maintained by budding, and inarching it upon common Chestnut stocks, in the same manner as other fruit-trees; but these variegated trees and plants are not so much regarded at present, as they were some years past.

The Dwarf branching Chestnut which is mentioned in most of the books, I take to be only a variety of the common; for Dr. Boerhaave shewed me some young trees in his garden near Leyden, which he had raised from nuts, which were sent him by Micheli from Florence, as the true fruit of the Dwarf Chestnut; but there appeared to be no difference between those, and some other which came from nuts of the large sort.

The third sort grows in South Carolina, from whence some of the fruit with their outer covers, were sent to his grace the Duke of Bedford, a few years past: these were as large and round as a tennis-ball, and armed all over with strong spines like a hedge-hog: these capsulæ were divided regularly in four cells, each containing one small Chesnut. At that time I compared these with father Plumier's description and figure, which he exhibited under the title of *Sloanea*, and found them to agree exactly; and upon looking through the box in which these were sent, I found some of the leaves of the tree, which also tallied with his description, which confirmed my former opinion; therefore, as I could see no other difference between the fruit of this and the common Chesnut, but its having four regular cells, divided by partitions, whereas those of the Chesnut have generally but three; therefore I have joined them together, being persuaded, that farther observations will justify my so doing.

It does not appear where Plumier found this tree growing naturally, though it is probable, it might be in Louisiana; for I think it could not be in either of the West India islands, where the heat is too great for this tree to thrive; though this is tender while young, for two or three young plants which were raised in England, did not survive the third winter.

The first of these trees was formerly in greater plenty amongst us than at present, as may be proved by the old buildings in London, which were for the most part of this timber; and in a description of London, written by Fitz-Stephens, in Henry the Second's time, he speaks of a very noble forest, which grew on the north part of it: *proxime (says he) patet foresta ingens, saltus numerosi ferarum, latebræ cervorum, damarum, aprorum, & taurorum sylvestrium, &c.* And there are now some remains of old decayed Chesnuts, in the woods and chaces not far distant from London, but particularly on Enfield Chace; which plainly proves, that this tree is not so great a stranger to our climate, as many people believe; and may be cultivated in England, to afford an equal profit with any of the other sorts of larger timber-trees, since the wood of this tree is equal in value to the best Oak, and, for many purposes, far exceeding it; as particularly for making vessels for all kinds of liquor, it having a property (when once thoroughly seasoned) of maintaining its bulk constantly, and is not subject to shrink or swell, as other timber is too apt to do: and I am certainly informed, that all the large casks, tuns, &c. for their wines in Italy, are made of this timber; and it is for that, and many more purposes, in greater esteem among the Italians, than any other timber whatever. It is also very valuable for pipes to convey water under ground, as enduring longer than the Elm, or any other wood. In Italy it is planted for coppice-wood, and is very much cultivated in stools, to make stakes for their Vines; which, being stuck into the ground, will endure seven years, which is longer than any other stakes will do, by near half the time. The usefulness of the timber, together with the beauty of the tree, renders it as well worth propagating as any tree whatever.

These trees are propagated by planting the nuts in February, in beds of fresh undunged earth. The best nuts for sowing, are such as are brought from Portugal and Spain, and are commonly sold in winter for eating, provided they are not kiln-dried, which is generally the case of most of those brought from abroad, which is done to prevent their sprouting or shooting in their passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of the growth of England, which are full as good to sow for timber or beauty, as any of the foreign nuts, though their fruit is much smaller: these should be preserved, until the season for sowing, in sand, where mice, or other vermin cannot come to them, otherwise they will soon destroy them: before you set them, it will be proper to put them into water, to try their goodness, which is known by their

ponderosity; those of them that swim upon the surface of the water should be rejected as good for nothing; but such as sink to the bottom, you may be sure are good.

In setting these seeds or nuts, the best way is, to make a drill with a hoe (as is commonly practised in setting Kidney Beans) about four inches deep, in which you should place the nuts, at about four inches distance, with their eye uppermost; then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for a conveniency of clearing the beds, &c. When you have finished your plantation, you must be careful that it is not destroyed by mice, or other vermin; which is very often the case, if they are not prevented by traps, or other means.

In April these nuts will appear above ground; you must therefore observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees, is either in October or the latter end of February; but October is the best season: the distance these should have in the nursery, is three feet row from row, and one foot in the rows: you must be careful in transplanting these trees, to take them up without injuring their roots, nor should they remain long out of the ground; but if they have a downright tap-root, it should be cut off, especially if they are intended to be removed again; this will occasion their putting out lateral roots, and render them less subject to miscarry when they are removed for good.

The time generally allowed them in this nursery, is three or four years, according to their growth; but the younger they are transplanted, if designed for timber, the better they will succeed; during which time you should be careful to keep them clear from weeds, observing also to prune off lateral branches, which would retard their upright growth; and where you find any that are disposed to grow crooked, either by their upper bud being hurt, or from any other accident, you may the year after planting, in March, cut them down to the lowermost eye next the surface of the ground, which will cause them to make one strong upright shoot, and may be afterwards trained into good strait trees: but this should not be practised, unless the plants have absolutely lost their leading shoot; for although the stems of the trees should be very crooked (as is generally the case with them when young) yet when they are transplanted out, and have room to grow, as they increase in bulk, they will grow more upright, and their stems will become strait, as I have frequently observed where there have been great plantations made of them.

But in doing of this, you must be careful not to disturb or break their roots, which, perhaps might destroy them. These trees require no other manure than their own leaves, which should be suffered to rot upon the ground; and in the spring of the year, the ground should have a slight digging, when these should be buried between their roots, but not too close to the trees, which might be injurious to their young fibres.

After having remained three or four years in the nursery, they will be fit for transplanting, either in rows to grow for timber, or in quarters for wilderness plantations; but if you intend them for timber, it is by much the better method to sow them in furrows (as is practised for Oaks, &c.) and let them remain unremoved; for these trees are apt to have a downright tap-root, which, being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, as is the case with the Oak, Walnut, &c.

Therefore, wherever any of these trees are planted for timber, they should remain unremoved: but where the fruit of them is more sought after, then it is certainly the better way to transplant them; for as

transplanting is a check to the luxuriant growth of trees, so it is a promoter of their fructification, as may be evinced by observing low shrubby Oaks, Walnuts, &c. which generally have a greater plenty of fruit, than any of the larger and more vigorous trees; and the fruit of such trees is much superior in taste, though the seeds of vigorous trees are vastly preferable for plantations of timber; for it is a constant observation, that, by saving seeds from dwarf trees or plants, from time to time, they may be rendered much lower in their growth than is their natural size; but where the fruit is most desired, then they should be taken from such trees as produce the largest and sweetest nuts, which are commonly found upon such trees as spread the most, and have horizontal roots; for the weaker trees being less capable to furnish a supply of nourishment, and having a greater quantity of fruit upon them, to which this must be distributed, together with their roots lying near the surface of the ground (by which means the juices are better prepared by sun, air, &c. before it enters their vessels,) it is certain their juices are better digested, and their fruits better matured, than those can possibly be, which grow upon strong vigorous trees, which have long tap-roots running several feet deep into the earth, and consequently take in vast quantities of crude unprepared juice, which is buoyed up to the extreme parts of the tree; and these seldom having many lateral branches, to digest and prepare their juice, by perspiring and throwing off the crude part before it enters the fruits.

And this, I dare say, universally holds good in all sorts of fruit trees, and is often the occasion of the good and bad qualities of the same sorts of fruits growing on the same soil.

What has been related about grafting this tree into the Walnut, to promote their bearing, or render their fruit fairer; or inoculating Cherries into the Chesnut, for later fruit, is very whimsical and silly, since neither the Chesnut nor Walnut will receive its own kind any other way than by inoculating or inarching; and it is the latter only, by which the Walnut can be propagated; nor was it ever known, that any two trees of a different genus would take upon each other, so as to produce either a good tree or fruit; therefore we may justly explode all those different graftings of various trees upon each other, so much talked of by the ancients; at least we may suppose those trees are not known by the same names now, that they are mentioned by in their writings; for I have made many trials upon them, which, although performed with great care, and in different seasons, yet scarcely one of them succeeded. But to return:

If you design a large plantation of these trees for timber, after having two or three times ploughed the ground, the better to destroy the roots of weeds, you should make your furrows about six feet distance from each other, in which you should lay the nuts about ten inches apart, covering them with earth about three inches deep; and, when they come up, you must carefully clear them from weeds: the distance allowed between each row, is for the use of the horse hoeing plough, which will dispatch a great deal of this work in a short time; but it should be performed with great care, so as not to injure the young plants; therefore the middle of the spaces only should be cleaned with this instrument, and a hand hoe must be used to clean between the plants in the rows, and also on each side, where it will be unsafe for the plough to be drawn: and in hand hoeing, there must be great care taken, not to cut the tender rind of the plants. If the following spring the spaces are carefully stirred with the plough, it will not only make the ground clean, but also loosen it, so as that the sun and moisture may more easily penetrate the same, which will greatly promote the growth of the plants; and the oftener these ploughings are repeated, the cleaner will be the ground, and the greater will be the progress of the plants, which cannot be kept too clean while they are young. When these have re-

mained three or four years (if the nuts succeeded well,) you will have many of these trees to remove, which should be done at the seasons before directed, leaving the trees about three feet distance in the rows; at which distance they may remain for three or four years more, when you should remove every other tree to make room for the remaining, which will reduce the whole plantation to six feet square, which will be distance enough for them to remain in, until they are large enough for poles, when you may cut down every other of these trees (making choice of the least promising,) within a foot of the ground, in order to make stools for poles, which, in eight or ten years time, will be strong enough to lop for hoops, hop poles, &c. for which purposes they are preferable to most other trees; so that every tenth year, here will be a fresh crop, which will pay the rent of the ground, and all other incumbent charges, and, at the same time, a full crop of growing timber left upon the ground: but as the large trees increase in bulk, their distance of twelve feet square will be too small; therefore when they have grown to a size for small boards, you should fell every other tree, which will reduce them to twenty-four feet square, which is a proper distance for them to remain for good; this will give air to the under wood (which, by this time, would be too much overhung by the closeness of the large trees;) by which means that will be greatly encouraged, and the small timber felled, will pay sufficient interest for the money at first laid out in planting, &c. with the principal also: so that all the remaining trees are clear profit, for the under wood still continuing, will pay the rent of the ground, and all other expences; and what a fine estate here will be for a succeeding generation, in about fourscore years, I leave every one to judge.

The Chinquapin, or Dwarf Virginian Chesnut, is at present very rare in England: it is very common in the woods of America, where it seldom grows above twelve or fourteen feet high, and produces great plenty of nuts, which are, for the most part, single in each outer coat or capsule. This tree is very hardy, and will resist the severest of our winters in the open ground, but is very apt to decay in summer, especially if it is planted in very dry ground. The nuts of these trees, if brought from America, should be put up in sand as soon as they are ripe, and sent to England immediately, otherwise they lose their growing quality, which is the reason this tree is at present so scarce with us; for not one seed in five hundred sent over ever grew, which was owing to the neglect of putting them up in this manner: indeed, most of the nuts which have been brought over, have been kiln-dried, to preserve them from sprouting, which infallibly destroys the germs. When the nuts arrive, they should be put into the ground as soon as possible; and if the winter should prove severe, it will be proper to cover the ground with leaves, tan, or Pease-haulm, to prevent the frost from penetrating the ground, so as to destroy the nuts. This sort of Chesnut delights in a moist soil; but if the wet continues long upon the ground in winter, it is apt to kill the trees. This will take by inarching it upon the common sort, but the trees so propagated seldom succeed well.

I have seen a specimen, and some nuts of a Dwarf Chesnut, which were brought from North America, which differed from all the other sorts; and I have been informed, that the French have raised plants of this kind, from the nuts which were brought from Canada; but as I have not seen any of the plants raised in England, I can give no farther account of it, than that some of the late writers have supposed it might be the dwarf branching kind before-mentioned.

CATANANCHE. Lin. Gen. Plant. 824. [*Kατάναγχω*, a violent allurements to love, of *κατά* and *ἀνάγω*, necessity, or of *κατάναγχω*, to compel; so called, because

C A T

because the opinion the ancients had of it, that it was a strong, and almost invincible inducement to love.] Candia Lions Foot.

The CHARACTERS are,

The flower is composed of many hermaphrodite florets, those on the border being longer than those which are in the center; these are included in one common scaly empalement, which is permanent and elegant. The florets are of one leaf, tongue-shaped, indented in five parts, and are longer than the empalement; these have each five short hairy stamina, terminated by cylindrical summits. The germen is situated below the flower, supporting a slender style the length of the stamina, crowned with a bifid stigma which is reflexed. The germen afterward becomes a single oval seed, which is compressed and crowned with bristles, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis; the flowers of this class have their stamina separate, and their summits connected together in a cylinder, and those of this section have only hermaphrodite flowers.

The SPECIES are,

1. CATANANCHE (*Cerulea*) squamis calycinis inferioribus ovatis. Hort. Cliff. 390. *Catananche whose under scales of the empalement are oval.* Catananche quorundam. Lugd. Hist. 1190.
2. CATANANCHE (*Lutea*) squamis calycinis inferioribus lanceolatis. Hort. Cliff. 390. *Catananche whose under scales of the empalement are spear-shaped.* Catananche flore luteo, latiore folio. Tourn. Inst. R. H. 478.

Tournefort mentions a third sort with a narrow leaf, in which it differs from the second; but if there is such a distinct species, I have not happened to meet with it; for although I have frequently received the seeds from several parts of Europe by this title, yet I could not find any difference between the plants, and those of the second sort; therefore I suppose Tournefort may have found the plants growing on a sterile soil, where the leaves were much narrower than those growing in a garden, or in better ground, which may have induced him to suppose they were distinct species. Both these plants grow naturally in the south of France, in Spain, Italy, and Candia, from whence it had the title of Candia Lions Foot.

The first sort sends out many long, narrow, hairy leaves, which are jagged on their edges like those of Buckthorn Plantain, but the leaves are broader, the jags deeper, and at greater distances; these lie flat on the ground, turning their points upwards, which are very narrow. Between the leaves come out the flower-stalks, which are in number proportionable to the size of the plant; for from an old thriving root, there is frequently eight or ten, and young plants do not send out more than two or three. These stalks rise near two feet high, dividing into many small branches upward, garnished with leaves like those below, but are smaller, and have few or no jags on their edges: each of the foot-stalks are terminated with single heads of flowers, having a dry, silvery, scaly empalement, in which are included three or four florets, whose petals are broad, flat, and indented at their ends; these are of a fine blue colour, having a dark spot at bottom, and in each the five stamina, with their yellow summits, standing a little above the petal, make a pretty appearance.

It has been by some authors titled Chondrilla cærulea, i. e. *Blue Gum Cicory*; and by others Sesamoides, or Catanances Sesamoides. Caspar Bauhin calls it Chondrilla cærulea cyani capitulo. Pin. 130. *Blue Gum Cicory with a Blue Bottle head.* There is a variety of this with double flowers, which is not very common in the English gardens.

The second sort hath broader leaves than the first, which are smoother, and less jagged on their edges: from each root arise two or three stalks, which grow a foot and a half high, sending out two or three slender foot-stalks, each sustaining a single head of yellow flowers, inclosed in a dry scaly empalement, of a darker colour than those of the first: as these flow-

C A T

ers are small, they make but little appearance, therefore the plant is only kept for the sake of variety.

The first of these plants is a perennial, and may be propagated by heads taken off the mother plant, either in spring or autumn; but those plants which are raised from seeds, are much stronger than those from slips. These plants are commonly planted in pots filled with light sandy soil, in order to shelter them in the winter from severe frosts; but if they are planted in warm borders, either near walls, pales, or hedges, in a moderately dry soil, they will endure abroad very well. It begins flowering in May, and continues till August or September (especially if the summer is not too dry,) is a pretty ornament to a garden, and is easily kept within bounds. This may also be propagated by seeds, which should be sown in a border of good light earth in March; and in May, when the plants are come up, they may be either transplanted into pots or borders, where they are to remain for flowering. These plants should remain unremoved when they are planted in the full ground, which will cause them to flower better, and they will produce more seeds. The seeds ripen in August.

The other sort is an annual plant, and therefore only propagated by seeds, which ripen very well in this country. The time for sowing them is early in March, in beds or borders of light earth where they are to remain, which will come up in a month or five weekstime, and require no other care but to keep them clean from weeds, and thin the plants where they are too close. These flower in June, and perfect their seeds in August or September; but as they have little beauty, they are not often kept in gardens.

CATAPUTIA MAJOR. See RICINUS.

CATAPUTIA MINOR. See EUPHORBIA.

CATARIA. See NEPETA.

CATCH-FLY. See LYCHNIS.

CATERPILLARS.

There are several kinds of this insect, which are very pernicious to a garden; but there are two sorts which are the most common, and destructive to the young plants: one of them is that which the white butterfly breeds. It is of a yellowish colour, spotted and striped with black; this commonly infests the tender leaves of Cabbages, Cauliflowers, and the Indian Cress: they eat off all the tender parts of the leaves, leaving only the fibres entire; so that very often we see, in the autumn season, whole gardens of winter Cabbages and Savoys almost destroyed by them, especially in those which are crowded with trees, or are near buildings. They always increase most in very dry seasons; and when the plants have been stunted by the drought, they are constantly attacked; whereas, those which are in vigour, seldom suffer much by these insects. Nor is there any other method found out to destroy them that I know of, but to pick them off the plants before they are spread from the nests; by which means, though perhaps many may be overlooked, yet their numbers will be greatly diminished. But this work must be often repeated during the warm weather, when the butterflies are abroad, which are continually depositing their eggs, and in a few days time will be metamorphosed to perfect caterpillars. But as these, for the most part, feed upon the outer leaves of plants; so they are more easily taken than the other sort, which is much larger: the skin is very tough, and of a dark colour: this is called by the gardeners, a grub, and is exceeding hurtful. The eggs of this sort of caterpillar, are, for the most part, deposited in the very heart or center of the plant (especially in Cabbages;) where, after it hath obtained its form, it eats its way out through all the leaves thereof; and also their dung, being lodged between the inclosed leaves of the Cabbages, gives them an ill scent.

This insect also burrows just under the surface of the ground, and makes great havock on young plants, by eating them through their tender shanks, and drawing

ing them into their holes. The mischief is chiefly done in the night: whenever you observe this, you should every morning look over your plat of plants; and wherever you see any plants eaten off, stir the ground round about the place with your fingers an inch deep, and you will certainly find them out. This is the only method I know of destroying them.

C A T K I N S, or I U L U S.

This is, by the botanists, called *Flos Amentaceus*: it is an aggregate of summits, which are joined together in form of a rope or cat's tail, and is the male flower of the trees which produce them; as the Firs, Pines, Cedars, Walnuts, Birch-trees, and Willows.

C A T E S B Æ A. Lin. Gen. Plant. 121. Hist. Carolin. Vol. II. p. 100. The Lily Thorn.

The CHARACTERS are,

It hath a small permanent empalement of one leaf, with five sharp indentures; the flower is of one leaf, funnel-shaped, having a very long tube, which gradually widens to the top, where it is four-cornered and spread open; it hath four stamina rising in the neck of the tube, terminated by oblong erect summits; the roundish germen is situated under the flower, supporting a slender style, crowned by a single stigma. The germen afterward becomes an oval berry with one cell, filled with angular seeds.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled *Tetrandria Monogynia*, the flower having four stamina and one style.

We have but one SPECIES of this plant, viz.

C A T E S B Æ A. Lin. Sp. Plant. 109. The Lily Thorn.

Frutex spinosus Buxi foliis, plurimis simul nascentibus, flore tetrapetaloides, pendulo, sordide flavo, tubo longissimo, fructu ovali croceo, semina parva continente. Catesb. Hist. Carol. Vol. II. p. 100.

This shrub was discovered by Mr. Catesby, near Nafau town, in the island of Providence, where he saw two of them growing, which were all he ever saw; from these he gathered the seeds, and brought them to England in 1726, from which many plants were raised in the English gardens, some of which have since flowered here.

It rises with a branching stem to the height of ten or twelve feet, which is covered with a pale russet bark; the branches come out alternately from the bottom to the top, which are garnished with small leaves, resembling those of the Box-tree, coming out in clusters all round the branches, at certain distances; the flowers come out single from the side of the branches, hanging downward; they are tubulous, and near six inches long, very narrow at their base, but widening upward toward the top, where it is divided into four parts which spread open, and are reflexed backward; these are of a dull yellow colour. After the flower decays, the germen swells to an oval fleshy berry the size of a middling Plumb, hollow within, and filled with small angular seeds.

This shrub is propagated by seeds, which must be procured from the country where it naturally grows. If the entire fruit are brought over in sand, the seeds will be better preserved: when they arrive in England, the seeds must be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark, and now and then moderately watered. If the seeds are good, the plants will appear in about six weeks after sowing; when, if the heat of the bed declines, the tan should be turned over to the bottom, and, if necessary, some fresh added to renew the heat, for these plants make but little progress the first year. When the pots are again plunged into the tan-bed, they must have fresh air admitted to them every day in proportion to the warmth of the season, and frequently refreshed with water, in small quantities, for much wet will certainly kill them; if the nights should prove cold, the glasses should be covered with mats every evening. As these plants grow slowly, they will not require to be removed out of the seed-pots the first year. In the autumn the pots should be removed into the stove, and plunged into the tan-bed. During the winter, the plants should

be watered with great caution, and in spring they should be carefully taken up, and each planted in a separate small pot filled with light sandy earth, and plunged into a fresh hot-bed of tanners bark, being careful to shade them until they have taken fresh root, as also to refresh them with water gently, as they may require it; and in summer, when the weather is warm, they should have a good share of air admitted to them; but in autumn must be removed into the stove, where they should constantly remain, and must be treated afterward in the same manner as other tender exotic plants.

This plant may be propagated by planting cuttings in small pots filled with light earth, during the months of June and July. The pots should be plunged into a moderate hot-bed of tanners bark, and the cuttings closely covered with small bell-glasses to exclude the external air. If this is properly performed, the cuttings will put out roots in about two or three months, when they may be carefully separated, planting each into a small pot filled with light earth, and plunged into the hot-bed again, and afterward must be treated as the seedling plants.

Most of those plants which were raised from Mr. Catesby's seeds, were killed by the severe winter in 1739; but seven years ago I received some fresh seeds, which succeeded so well, as to enable me to communicate plants to several curious persons in England and Holland.

C A C A U L I S, Bastard Parsley.

This is one of the umbelliferous plants with oblong seeds, which are a little furrowed and prickly: the petals of the flower are unequal and heart-shaped.

There are several species of this plant preserved in the botanic gardens; but as there is no great beauty or use in any of them, I shall pass them over with only observing, that if any person hath a mind to cultivate them, the best season to sow their seeds is in autumn, soon after they are ripe; for if the seeds are kept till spring, the plants seldom produce ripe seeds again. They are most of them biennial, and require to be sown every year. We have four or five species of them, which grow wild in England.

C A U L I F E R O U S plants [of *Caulis*, *Lat.* a stalk, and *fero*, to bear;] such plants as have a true stalk.

C A U L I S, is that part of a plant which rises single above the earth, from whence the leaves or little branches put forth, as Jungius defines it; or it is the upper part of a plant stretched forth to an height, so that the fore parts differ not from the hind, nor the right from the left. In trees and shrubs it is called *Caudix*; in corn *Culmus*; the stalk of any herb; the stem, trunk, or body of a tree. *Lat.*

C E A N O T H U S. Lin. Gen. Plant. 237. Euonymus. Com. Hort. New Jersey Thea.

The CHARACTERS are,

It hath a turbinated empalement of one leaf, which is permanent, cut into five acute segments which close together; the flower hath five roundish equal petals which spread open, and are less than the empalement; it hath five erect stamina, placed opposite to the petals, and are of equal length, terminated by roundish summits, and a three-cornered germen, supporting a cylindrical style, crowned by an obtuse stigma. The germen afterward becomes a dry capsule with three cells, in which are lodged three oval seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled *Pentandria Monogynia*, the flower having five stamina and one style.

The SPECIES are,

1. C E A N O T H U S (*Americanus*) foliis trinerviis. Lin. Sp. Plant. 195. *Ceanothus* with leaves having three nerves. Euonymus Nervi Belgii corni fœminæ foliis. Hort. Amst. 1. 167. *New England Dogwood* with female *Cornel* leaves, commonly called *New Jersey Thea*.
2. C E A N O T H U S (*Africanus*) foliis lanceolatis enerviis, stipulis subrotundis. Lin. Sp. Plant. 196. *Ceanothus* with spear-shaped leaves without nerves, and roundish stipula. *Alaternoides Africana lauri ferratæ folio*. Com. Præl. 61. tab. 11,

3. C E A N O T H U S

3. *CEANOTHUS (Arborescens)* foliis ovatis sessilibus nervosus floribus alaribus. *Ceanothus with oval nervous leaves set close to the branches, flowers proceeding from the wings of the leaves, commonly called Red-wood.*

The first sort grows naturally in most parts of North America, from whence great plenty of the seeds have been of late years brought to Europe, by the title of New Jersey Thea, where I have been informed the inhabitants dry the leaves of this shrub to use as Thea. The people of Canada use the root in venereal cases. I have received the seeds of this sort from New England, Pensylvania, Virginia, and Carolina; and the French mention it as a common shrub in Canada, where they say the cattle browse upon it, and keep it very low.

In England this shrub seldom rises more than three or four feet high, sending out branches on every side from the ground upward. The branches are very slender, and as it is pretty late in the spring before they begin to shoot, they keep growing very late; therefore, unless the autumn proves dry and mild, the tender shoots are often killed down very low by the early frosts; but, in favourable seasons, the extreme parts of the shoots only are injured by the cold. These branches are garnished with oval pointed leaves, having three longitudinal veins running from the foot-stalk to the point, which diverge in the broad part of the leaves from each other: the leaves are placed opposite, and are of a light green colour. At the extremity of each shoot the flowers are produced in close thick spikes, which are composed of five small leaves, of a clear white. These appear in July, and make a pretty appearance during their continuance; for, as every shoot is terminated by one of these spikes, the whole shrub is covered over with flowers, the branches commonly growing very close to each other; and when the autumn proves mild, these shrubs often flower again in October. After the flowers are past, there succeeds to each flower a tricapsular seed-vessel, flattened at the top, opening into three cells, each having a single seed. In warm seasons the seeds ripen in England. This shrub is best propagated by seeds, which should be sown in the autumn in small pots, and plunged into an old hot-bed, where they may remain during the winter, exposing them in mild weather to the open air, but in frost they must be protected from cold. In March the pots should be plunged into a moderate hot-bed to bring up the plants, which should be inured to bear the open air by degrees; and as soon as they have obtained a little strength, they should be exposed in a sheltered situation till autumn, when they must be placed under a hot-bed frame, to screen them from severe frost in winter; but in mild weather they should be fully exposed to the open air, for while the plants are young, they will not endure the cold of the winter. In the following spring, before the plants begin to shoot, they should be transplanted; some of them may be put into separate pots, and the others into a nursery-bed, in a warm situation, where they may remain a year or two to get strength, after which time they may be removed to the places where they are designed to remain. They should have a moderately dry soil and a sheltered situation, where they will thrive and flower extremely well; but in stiff cold land, they are always very late in the spring before they come out, so that their young shoots are full of sap in the autumn, and the first frost commonly kills their tops, which frequently causes them to die great part of their length.

It may also be propagated by laying down the young branches, which, in a light soil, will put out roots in a year's time, but these layers should not be much watered; for as the shoots are tender, moisture will often occasion their rotting, when it is given in quantities, or too often repeated; therefore the best method is to cover the surface of the ground in dry weather, all round the layers, either with mulch or rotten tan, which will preserve a sufficient moisture in the ground, provided the season is not extremely dry;

in which case they should have a little water once in eight or ten days, which will be sufficient.

The best time for laying down these branches is in autumn; and if after this is performed, the surface of the ground is covered over with some old tan, taken from a decayed hot-bed, it will prevent the frost from penetrating the ground, which will secure them from injury; and the same covering will prevent the winds from drying the ground in the spring, and thereby promote their putting out roots. These layers, when rooted, may be taken up the following spring, and treated in the same manner as those raised from seeds.

The second sort grows naturally at the Cape of Good Hope, from whence it was originally brought to Holland, and has been many years preserved there; and since has been communicated to most of the curious gardens in Europe, where it has been long known by the title of *Alaternoides*, &c. and by some authors it is titled *Ricinoides Africana arborescens*, &c. but Dr. Linnæus, having examined the characters more exactly, has joined it to this genus.

This rises to the height of ten or twelve feet, with a woody stem, covered with a rough dark-coloured bark, and sends out many weak branches, which hang downward; these while young are green, but afterward change to a purplish colour. They are garnished with oblong pointed leaves, of a lucid green, which are smooth, and slightly sawed on their edges. The flowers are small, of an herbaceous colour, coming out from the side of the branches; these sometimes appear in July, but are not succeeded by seeds in this country, nor do the plants often produce flowers; so that they are preserved only for the beauty of their shining evergreen leaves, which make a variety in the green-house during the winter season.

It may be propagated either by layers or cuttings; the latter being a very sure and expeditious method, is generally preferred. The cuttings should be planted in the spring into pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, observing to shade them in the heat of the day, and now and then refresh them with water. In about two months or less, they will have taken root, when they must be gradually inured to the open air, placing them in a sheltered situation till they have obtained strength, when they may be separated, and each planted in a small pot filled with light earth, placing them in the shade till they have taken fresh root; then they may be removed, and intermixed with other exotic plants for the summer season. In autumn they must be housed with Myrtles, and other more hardy exotic plants; and treated in the same manner.

The third sort grows naturally in the Bahama Islands, from whence the late Mr. Catesby brought the seeds to England. It also grows naturally in Barbadoes, and some other islands in the West Indies, from whence I have received the seeds. This, in the countries of its natural growth, rises to the height of forty or fifty feet; with large trunks, which are by the inhabitants sawn into boards, and were at first esteemed for the beauty of their colour; but being exposed to the air, their colour vanished and they became pale, so have not since been much regarded.

In Europe, where the plants have been properly treated, they have grown to the height of twenty feet; and if the stoves in which they were placed had been lofty enough, would have grown much higher. The stem is strong, woody, and is covered with a light brown bark, which, when young, has several furrows; the branches come out irregularly from every side the stem, garnished with pretty large oval leaves, of a light green colour, having several longitudinal veins inclining to white. The flowers are small, of an herbaceous white, so make little appearance; they come out from the wings of the leaves, and, in their native soil, are succeeded by roundish fruit almost the size of small Pease, opening in three cells; in each is inclosed one shining black seed.

This is propagated by seeds, which should be sown in the spring, in small pots filled with light earth, and plunged into a hot-bed; these seeds lie generally two months in the ground before the plants make their appearance, during which time the pots should be duly watered, and air admitted when the weather is warm. When the plants come up and are fit to remove, they should be carefully separated, planting each in a small pot filled with light earth, watering the earth to settle it about their roots; then plunge them into the tan-bed again, shading the plants from the sun till they have taken new root; afterward they may be treated in the same manner as other tender plants from the same countries. When the plants have obtained strength, they may be preserved in winter in a dry stove, but these will not make such progress as those in the tan-stove.

C E C R O P I A. Yaruma Oviedi. Sloan. Hist. Jam. The Trumpet-tree, or Snakewood.

The CHARACTERS are,

It hath male and female flowers in different plants. The male flower hath an oval acute spathe, which bursts and contains a tale composed of many katkins, which are taper and bundled together; these are imbricated, and have many turbinate scales, which are four-cornered, obtuse, and compressed. The flower hath no corolla, but a scaly nectarium, with two short hair-like stamina, crowned by four-cornered oblong summits. The female flowers have a spathe, with four taper imbricated germen; they have no corolla, but the compressed imbricated germen support one short style, crowned by a headed torn stigma. The empalement afterward turns to a berry with one cell, containing one oblong compressed seed.

This tree is ranged in the second order of Linnæus's twenty-second class, intitled Diœcia Diandria, the male flowers growing upon separate plants from the female, and have each two stamina.

It grows naturally in most of the woody parts of the island of Jamaica, where it rises to the height of thirty-five or forty feet: the trunk and branches are hollow, and stopped at different spaces by membranaceous septæ, which have so many light annular marks in the surface; the leaves are large, divided into many lobes like those of Papaya, but the footstalk is placed more in the center, so as to resemble a target: they are downy on their under side. The flowers are inclosed in a conical spathe or sheath, the male growing upon separate plants from those which have the female; they are produced upon imbricated katkins, composed of several turbinate scales, having no corolla, each having a scaly nectarium, with two short hair-like stamina, crowned with four-cornered oblong summits. The female flowers are inclosed in a conical spathe or sheath; these have no corolla, but have four imbricated germen, supporting one short style, crowned by a headed torn stigma. The empalement afterward turns to an oblong cylindrical berry, composed of many small acini like the Strawberry, and much resemble it in flavour when ripe.

This tree is very rare at present in Europe; the fruit being small are generally devoured by birds, so are not much observed by the European inhabitants, but the negroes are fond of it; they also make use of the small branches of the tree to obtain fire, by rubbing them against each other; by this attrition they soon emit sparks of fire, so that it is a useful tree in that country.

I received specimens of this tree from the late Dr. Houstoun, who found it growing naturally at La Vera Cruz, in New Spain, but without flowers; nor had the Doctor leisure to examine the characters of it, so that at present we are not sufficiently acquainted with them.

It may be propagated by seeds (when procured from the places where it naturally grows.) These should be brought over in sand; for as the fruit are composed of several acini like those of Strawberries, so if they are put up moist in papers, they will be apt to grow mouldy, and thereby spoil the seeds: but

when they are put up in light sand, it will prevent that inconveniency. The seeds should be sown in small pots filled with light earth, and plunged into a moderate hot-bed of tanners bark, observing to water the pots duly, and to admit fresh air whenever the weather is favourable. When the plants come up and are fit to transplant, they should be carefully taken up, and each planted in a separate small pot filled with the like light earth, and plunged into the hot-bed again, being careful to water them to settle the earth to their roots, and also to screen them from the sun till they have taken new root: after which they should be constantly kept plunged into the bark-bed in the stove, and treated in the same manner as other plants from the same country.

C E D R U S. The Cedar-tree of Barbadoes, and the Mahogany, &c.

The CHARACTERS are,

It hath a tubulous bell-shaped empalement of one leaf, indented in five parts. The flower is of one leaf, divided at the top into five parts; it hath five short stamina, which adhere at bottom to the germen, and are terminated by roundish summits; in the center is situated the roundish germen, supporting a thick stigma; the germen afterward becomes an oval pod, having five cells, opening from the bottom upward with five valves, having a double cover; the outer being thick and woody, the inner very thin, which immediately surrounds the seeds. In the center is fixed a five-cornered column the length of the pod, whose angles are opposite to the fissures of the pod, to which the seeds adhere, placed over each other like the scales of fish; these are thick at their base, but upward are flat and thin, like the wings adhering to the seeds of Firs and Pines.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one germen.

As the Cedar of Libanus is by Tournefort very properly referred to the genus of Larix, and all the berry-bearing Cedars are joined to the Junipers, I have given the title of Cedrus to this genus, as they were mentioned by imperfect titles by most of the authors who have treated of them; and as the first sort has been generally known by the appellation of Cedar in the countries where it naturally grows, the applying the same name to those plants which agree in their essential characters with it, will join them properly together.

The SPECIES are,

1. **CEDRUS** (*Oderata*) foliis pinnatis, foliolis multijugatis obtusis, fructu ovali glabro. *Cedar-tree with winged leaves, composed of many pair of small leaves or lobes, which are obtuse, and an oval smooth fruit.* Cedrus Barbadosium, alatis fraxini foliis non crenatis, fructu singulari, quinis involucris crassis validis cochleato cavis, totidem semina membranis adacta & columnæ canaliculatæ pentagonæ prægrandi adnata, occludentibus ornato. Pluk. Phyt. tab. 157. f. 1. *The Barbadoes Cedar-tree.*
2. **CEDRUS** (*Mahogani*) foliis pinnatis, foliolis oppositis, glabris, floribus racemosis sparsis. *Cedar with winged leaves, whose lobes are smooth and stand opposite, and flowers growing in loose bunches.* Arbor foliis pinnatis, nullo impari alani claudente, nervo ad latus unum excurrente fructu anguloso magno, semine alato instar Pinus. Catesb. Hist. Carol. Vol. II. p. 181. *The Mahogany-tree.*
3. **CEDRUS** (*Alternifolius*) foliis alternis simplicibus, cordato-ovatis acutis, fructu pentagono mucronato. *Cedar with single leaves placed alternately, which are oval, heart-shaped, and acute, having a five-cornered pointed fruit.* Arbor excelsa Coryli folio ampliore. Houst. MSS. The first sort is commonly known under the title of Cedar in the British islands of America, where this tree grows naturally, and is one of the largest trees of that country. The trunks of these trees are so large, that the inhabitants hollow them, and form them into the shape of boats, and periaguas, for which purpose they are extremely well adapted; the wood

wood being soft, it may be cut out with great facility, and being light, it will carry a great weight on the water. There are canoes in the West Indies, which have been formed out of these trunks, which are forty feet long and six broad; the wood is light, of a brown colour, and has a fragrant odour, from whence the title of Cedar has been given to it. This wood is frequently cut into shingles for covering of houses, and is found very durable; but as the worms are apt to eat this wood, it is not proper for building of ships, though it is often used for that purpose, as also for sheathing of ships. It is often used for wainscoting of rooms, and to make chests, because vermin do not so frequently breed in it, as in many other sorts of wood, this having a very bitter taste, which is communicated to whatever is put into the chests, especially when the wood is fresh; for which reason it is never made into casks, because spirituous liquors will dissolve part of the resin, and thereby acquire a very bitter taste.

This tree rises with a strait stem to the height of seventy or eighty feet, while young the bark is smooth, and of an Ash-colour; but as they advance, the bark becomes rough and of a darker colour. Toward the top it shoots out many side branches, garnished with winged leaves, composed of sixteen or eighteen pair of lobes (or small leaves) so that they are sometimes near three feet long; the lobes are broad at their base, and are near two inches long, blunt at their ends, and of a pale colour; these emit a very rank odour in the summer season, so as to be very offensive. As I have not seen any of these flowers upon the trees, I can give no description of them. The fruit is oval, about the size of a partridge's egg, smooth, of a very dark colour, and opens in five parts, having a five-cornered column standing in the middle, between the angles of which the winged seeds are closely placed, lapping over each other like the scales of fish.

There are some plants of this sort in England, which are preserved in the gardens of those who are curious in collecting exotic plants; these have been raised from the seeds which have been brought from Barbadoes, but they are too tender to live in the open air in England; therefore these plants should be treated in the same manner as the Mahogany next mentioned, but they are of much quicker growth; for in four years from the seed, I have had the plants upward of ten feet high.

I have received plants of this kind from Paris, by the title of *Semiruba*; but whether the root of this tree is what they use in medicine under that appellation, I cannot say. The seeds of this have also been sent me from the French islands in America, by the title of *Acajou Cedre*.

It is propagated by seeds, which may be easily procured from the American islands, which must be sown upon a hot-bed in the spring, and the plants treated in the same manner as the next.

The second sort is the Mahogany, whose wood is now well known in England.

This tree is a native of the warmest parts of America, growing plentifully in the islands of Cuba, Jamaica, and Hispaniola; there are also many of them on the Bahama Islands, but I have not heard of their being found in any of the Leeward Islands. In Cuba and Jamaica there are trees of a very large size, so as to cut into planks of six feet breadth; but those on the Bahama Islands are not so large, though they are frequently four feet diameter, and rise to a great height, notwithstanding they are generally found growing upon the solid rocks, where there is scarce any earth for their nourishment. The wood which has been brought from the Bahama Islands has usually passed under the appellation of *Madeira wood*, but there is no doubt of its being the same as the Mahogany. The Spaniards make great use of this wood for building of ships; for which purpose it is better adapted, than any other sort of wood yet known, being very durable, resisting gun shots, and burying

the shot without splintering; nor is the worm so apt to eat this wood as that of the Oak, so that for the West Indies the ships built of Mahogany are preferable to any other.

The excellency of this wood for all domestic uses, is now sufficiently known in England; and it is matter of surprise, that the tree should not have been taken notice of by any historian or traveller to this time; the only author who has mentioned this tree, is Mr. Catesby, in his *Natural History of Carolina*, and the Bahama Islands, before whom I believe neither the tree or the wood was taken notice of by any writer on natural history, although the wood has been many years brought to England in great quantities.

In the West Indies these trees are of so quick growth, as to arrive to a large size in a few years; the manner of their propagation in the Bahama Islands, as it is described by Mr. Catesby, is as follows: when the fruit is ripe, the outer hard shell or covering separates at the bottom, next the foot-stalk, thereby exposing the seeds, which are fastened to a hard five-cornered column, standing in the middle; these seeds being broad and light, are dispersed on the surface of the ground, which is very rocky. Such of the seeds as happen to fall into the fissures of the rock, very soon send forth roots; and if these tender fibres meet with resistance from the hardness of the rock, they creep out on the surface of it, and seek another fissure, into which they creep, and swell to such a size and strength, as to break the rock, and thereby make way for the root's deeper penetration; and by this nourishment from the rock, the trees grow to a large size in a few years.

The leaves of this tree are winged-like those of the Ash, having commonly six or eight pair of pinnæ (or lobes) which are shorter and broader at their base than those of the Ash, where they adhere to the midrib by very short foot-stalks; these lobes are very smooth, having but one vein running through each, which is always on one side, so as to divide them unequally. We have no perfect account of the flower of this tree; those which are exhibited in Mr. Catesby's *Natural History*, were drawn from a withered imperfect fragment, which were the only remains of the flowers which could be found at the time when he was there; but the fruit he has delineated very exactly, as I have had opportunity of comparing it with some which have been brought to England. The entire fruit, before it opens, is of a brown colour; these fruit grow erect, upon foot-stalks, which closely adhere to the five-cornered column, running through the middle of the fruit, and to which the seeds are fastened, lying imbricatum like slates on a house, over each other; so that when the fruit is ripe, the outer cover divides at the bottom into five equal parts, and when these fall off, and the seeds are dispersed, the foot-stalk and the column remain some months after on the tree.

It is propagated by seeds, which may be easily procured from the Bahama Islands, from whence most of the good seeds which have come to England were brought; for most of these which have been sent from Jamaica, although brought in their pods, have not succeeded; whereas, those from the Bahama Islands, have grown as well as if they were immediately taken from the trees. The seeds should be sown in small pots filled with light sandy earth, and plunged into a hot-bed of tanners bark, giving them a gentle watering once a week: if the seeds are good, the plants will appear in five or six weeks; and when they are two inches high, a sufficient number of small pots should be filled with light earth, and plunged into the tan-bed a day or two, that the earth may be warmed before the plants are put into the pots; then the young plants should be shaken out of the pots, and carefully separated, so as not to tear their roots, and each planted in a single pot, being careful to shade them till they have taken fresh root; after which they must be treated in the same manner as other tender plants from the

the same climate, being careful not to give them much water, especially in winter; as also when they are shifted, to preserve the earth about their roots, otherwise they are very subject to perish; for in the country where they grow naturally, they say it is not possible to remove these trees so as to live; if the plants are properly managed, they will make considerable progress. I have some plants now in the Chelsea garden, more than twelve feet high, which are but of eight years growth from seeds.

As the wood of this tree is now so generally used in England, so it might surely be worthy of the care of the planters in America, many of whom are possessed of barren rocky lands, which at present produce no profit; but if the seeds of this tree were sown there, might turn out greatly to the advantage of their successors, though the present possessors should not live to enjoy the profit; but I fear there are few of the gentlemen in those islands, who extend their thoughts so far, as to make provision for the rising generation.

The third sort was discovered by the late Dr. Houstoun at Campeachy, from whence he sent the seeds to England, which succeeded in several gardens; when the doctor first observed these trees, they were destitute of leaves, but were loaded with ripe fruit; and on his second visit to the place, he found the trees in full verdure, but no appearance of flowers, so he was at a loss to know what genus it belonged to; but as the fruit of the trees agree exactly with those of the two former species, so I have ventured to join it to them.

These trees usually rise to the height of eighty feet, or upward, and divide into many large branches toward the top; garnished with leaves, somewhat resembling those of the Witch Hazel, but are broader at their base, and cut angular at their top; these are of an Ash-colour underneath, and are set on the branches without any order; the fruit of this tree is much larger than that of the Barbadoes Cedar, being broad at the base, and diminishing gradually to the top, where it terminates in a point, being upwards of two inches long; this has also a column, or woody core, running lengthways through the fruit, to which the winged seeds adhere as in the two former; but as both their fruit are smooth on the outside, this differs from them, in having five angles running from the base upward; at each angle the fruit, when ripe, separates, and exposes the winged seeds, which are dispersed by the winds.

We have no account of the wood of this tree, whether it is ever used in buildings, or other purposes, as there have been few persons of any curiosity in that country, the cutters of Logwood being the chief people who inhabit there, from whom there can be little known of the produce. The plants which have been raised from the seeds in England, have made great progress for the two first years, but afterward were but slow of growth; for, in six years more, they did not shoot so much as in the first year from the seed, when they grew more than three feet high. I made several trials to propagate the trees by cuttings and layers, but without success; so that by seeds, seems to be the only method of having them; these may be raised and managed in the same manner as the two foregoing sorts, and with them constantly kept in the bark-stove.

CELASTRUS. Lin. Gen. Plant. 392. Euonymoides. Inard. Ac. R. Sc. 1716. The Staff-tree.

The CHARACTERS are,

The flower hath a small one leaved empalement, cut into five unequal blunt parts. The flower hath five oval pe-

tals, which are equal, and spread open. It hath five stamina as long as the petals, terminated by small summits, and a small germen with a large receptacle, marked with ten deep channels, supporting a short style crowned with an obtuse trifid stigma. The germen afterward becomes an oval, blunt, three-cornered capsule, opening in three cells, each containing an oval smooth seed.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, from the flower having five stamina and one style.

The SPECIES are,

1. CELASTRUS (*Bullatus*) inermis, foliis ovatis integerrimis. Lin. Sp. Plant. 196. Smooth Staff-tree with oval entire leaves. Euonymus Virginianus, rotundifolius capsulis Coccineis eleganter bullatis. Pluk. Alm. 139.
2. CELASTRUS (*Scandens*) inermis, caule volubili foliis serrulatis. Lin. Sp. Plant. 285. Smooth Staff-tree with a twining stalk, whose leaves are slightly sawed. Euonymoides Canadensis scandens foliis serratis. Inard. Ac. Reg. 1716.
3. CELASTRUS (*Pyracanthus*) spinis nudis, ramis teretibus, foliis acutis. Hort. Cliff. 72. Staff-tree with naked spines, taper branches, and pointed leaves. Lycium Æthiopicum pyracanthæ foliis. Hort. Amst. 1. p. 163.
4. CELASTRUS (*Buxifolius*) spinis foliosis, ramis angulatis, foliis obtusis. Hort. Cliff. 73. Staff-tree with leaves on the spines, angular branches, and obtuse leaves. Lycium Portoricense, Buxi foliis angustioribus. Pluk. Alm. 234. tab. 202. f. 3.
5. CELASTRUS (*Myrtifolius*) inermis, foliis ovatis serrulatis, floribus racemosis caule erecto. Hort. Cliff. 72. Staff-tree without spines, oval sawed leaves, flowers in long bunches, and an erect stalk. Myrtifolia arbor, foliis latis subrotundis, flore albo. Sloan. Hist. Jam. 2. p. 79. tab. 193.

The first sort grows naturally in Virginia, and many other parts of North America, where it rises to the height of eight or ten feet; but in England there are few of them much more than half that height. It generally puts out two or three stems from the root, which divide upward into several branches, covered with a brown bark, garnished with leaves near three inches long, and two broad, which are placed alternately on the branches; the flowers come out in loose spikes at the end of the branches; these are white, made up of five oval petals, with a germen in the center, attended by five stamina: when the flowers fall off, the germen swells to a three-cornered capsule, of a scarlet colour, set full of small protuberances; this opens in three cells, each containing a hard oval seed, covered with a thin red pulp. This shrub flowers in July, but rarely produces good seeds in England.

It is propagated here by layers, which will take root in one year; the young branches only are proper for this purpose, so that where there is not any of these near the ground, the main stalks should be drawn down, and fastened with pegs to prevent their rising, and the young shoots from them should be laid. The best time for doing this is in autumn, when they begin to cast their leaves, and by that time twelve-month they will be sufficiently rooted, when they should be cut from the old plant, and planted in a nursery for two or three years to get strength; after which they must be removed to the places where they are to remain. This shrub grows naturally in moist places, so will not thrive well in a dry soil. It is very hardy, and bears the cold of our winters very well. It is also propagated by seeds, which are frequently brought from America; but as these rarely arrive here time enough to sow before the spring, so the plants never come up the first year; therefore the seeds may be sown either in pots, or in a bed of loamy earth, keeping them clean from weeds during the summer; and those in the pots should be placed in the shade till the autumn, when the pots should be either plunged into the ground in a warm situation, or placed.

C E L

placed under a common frame, to prevent the frost from penetrating through the side of the pots; and if the surface of those which are plunged in the ground, and also the bed where the seeds are sown are lightly covered with some old tan from a decayed hot-bed, it will secure the seeds from being hurt by severe frosts. In the spring the plants will come up, which must be kept clean from weeds, and, if the season proves dry, they should have water now and then, which will greatly forward their growth. If the plants make good progress the first summer, they may be transplanted into a nursery in autumn, otherwise they should remain in the seed-bed till the second year; when they may be treated in the same manner as the layers.

The second sort sends out several ligneous stalks from the root, which are flexible, and twist themselves about whatever trees and shrubs grow near them, or when they are at a distance from such support, they twine about each other, and rise to the height of twelve or fourteen feet; but when they fasten themselves about trees they will grow much taller, but wherever this happens, their branches girt the trees so closely, as in a few years will destroy them. These are garnished with leaves about three inches long, and near two broad, which are sawed on their edges, and placed alternately on the branches; they are of a lively green above, and paler on their under side, having several transverse nerves from the middle to the side. The flowers are produced in small bunches toward the end of the branches, which are of an herbaceous colour, composed of five roundish petals; these are succeeded by roundish three-cornered capsules, which are red when ripe, spread open in three cells, disclosing the seeds in the same manner as our common Spindle-tree. This flowers about the beginning of June, and the seeds ripen in autumn. The seeds of this sort generally ripen well in England, and the plants may be propagated from the seeds, or by layers, in the same manner as the former sort; it delights in a strong loamy soil, rather moist than dry, and will grow in woods among other trees and shrubs, where, when the fruit is ripe, they make a pretty appearance. It grows naturally all over North America, and is extremely hardy.

The third sort is a native of Ethiopia, from whence the seeds were first brought to the gardens in Holland, where the plants were propagated, and have been since communicated to most of the curious gardens in Europe. This rises with an irregular stalk about three or four feet high, sending out several side branches, covered with brown bark, garnished with leaves about two inches long, and more than half an inch broad, some of which are pointed, and others are obtuse; they are stiff, of a lucid green, and come out irregular from the branches; these continue green through the year. The flowers are produced from the sides of the branches in loose tufts, many of them arising from one point, standing upon long foot-stalks; they are of an herbaceous white colour, composed of five petals, which spread open, and five spreading stamina, which surround a swelling germen, supporting a tapering style, crowned by an obtuse trifid stigma; the germen afterward becomes an oval fruit, of a fine red colour, which opens in three cells, containing one oblong hard seed, the other two cells being generally empty.

This plant is commonly propagated by cuttings in Europe, which is more expeditious than raising them from seeds, because the seeds rarely come up the first year. The cuttings may be planted any time in summer; but those which are planted early, will have more time to get strength before winter. They should be planted in small pots, which will contain four cuttings in each; the earth of a kitchen garden, which is well cultivated, is as good as any for this purpose. The pots should be then plunged into a moderate hot-bed, and shaded from the sun every day, and gently refreshed with water now and then; when they have taken root they must be gradually

C E L

exposed to the open air, and then placed in a sheltered situation till they have obtained strength, when they should be separated, and planted each in a small pot filled with the same earth, then placed in the shade till they have taken fresh root; after which they may be placed with other exotic plants in a sheltered situation till autumn, when they must be housed with Myrtles, and other hardy green-house plants, and will require the same treatment.

This plant has been titled African Barberry by some ignorant persons, I suppose from the resemblance of its fruit to that of the Barberry.

The fourth sort grows naturally at the Cape of Good Hope, from whence I received the seeds. This rises with a slender ligneous stalk to the height of ten or twelve feet, covered with a light Ash-coloured bark, and full of joints, which are armed with long spines, upon which grow many small leaves; the branches are slender, and armed with the same spines at every joint, but the whole plant is so weak, as to require some support, without which they would fall to the ground. The leaves come out in clusters without any order, which are shaped somewhat like those of the narrow-leaved Box-tree, but are longer, and of a loose texture; the branches are angular, and when young their bark is whitish. As I have not seen the flowers of this shrub, I can give no farther description of it.

This rises very easily from seeds, and the plants make great progress; for I have raised them four feet high in two years from seeds, without any artificial heat; and some of the plants have lived thro' two winters against a south-east wall, but these have shed their leaves in winter, whereas those which were removed into the green-house have retained their verdure through the year.

It may be propagated by cuttings, which should be planted in the spring, and treated in the same manner as hath been directed for the former sort; or if the young shoots are laid, they will take root in one year, and may then be transplanted either into pots, or against a good aspected wall, where I find they will endure our ordinary winters without any protection; and if they are covered in severe frosts, they may be brought, when old, to live abroad without protection. Those in pots will require a little shelter in winter, but should not be tenderly treated, for that will cause them to have weak branches, nor will the leaves have so much verdure, as when they are exposed to the open air in mild weather.

The fifth sort grows naturally in Jamaica, and also in some of the other islands in the West Indies, where it rises to the height of eighteen or twenty feet, sending out many side branches, garnished with leaves somewhat like those of the broad-leaved Myrtle, which are slightly sawed on their edges; the flowers come out from the side of the branches in long bunches; they are white, and composed of five petals, having five stamina placed opposite to them, and a germen in the center which is channelled; this afterward becomes a fruit, having five cells, each inclosing an oblong seed.

This plant is at present rare in England, for the seeds seldom grow the first year; therefore when the seeds arrive here, they should be sown in small pots filled with light earth, and plunged into a tan-bed, where they should remain till the following spring, when they should be plunged into a fresh hot-bed of tanners bark; and if the pots are duly watered, the plants will appear in about a month after; when these are fit to remove, they should be planted into separate small pots, and plunged again into the tan-bed, being careful to water and shade them till they have taken new root, after which they should be treated in the same manner as other tender plants from the same countries.

CELERY or SALARY. See APIUM.

CELLS of plants [of *Cellæ*, *Lat.*] are those partitions or hollow places in the husks or pods of plants, in which the seed is contained.

H h h

CELOSIA.

CELOSIA. Lin. Gen. Plant. 255. Amaranthus. Tourn. Inst. R. H. 234. tab. 118. Amaranth.

The CHARACTERS are,

The empalement is permanent, and composed of three dry coloured leaves. The flower hath five erect sharp-pointed petals, which are permanent, stiff, and shaped like a flower-cup. It hath a small nectarium joined to the border of the germen, to which adhere the five stamina, which are terminated by turning summits. The globular germen supports an upright style, which is as long as the stamina, crowned with a single stigma. The empalement afterward becomes a globular capsule with one cell opening horizontally, containing roundish seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CELOSIA (*Margaritacea*) foliis ovatis stipulis falcatis, pedunculis angulatis, spicis scariosis. Lin. Sp. Plant. 297. Celosia with oval leaves, a saulcbion-shaped stipula, and a rough spike. Amaranthus spicâ albescente habitore. Martyn. Cent. 1. p. 7.
2. CELOSIA (*Cristata*) foliis lanceolato-ovatis recurvis subundatis pedunculis angulatis, spicis oblongis cristatis. Lin. Sp. 297. Celosia with oval spear-shaped leaves, angular foot-stalks, and oblong crested spikes of flowers. Amaranthus cristatus. Camer. Epit. 792. Crested Amaranth, commonly called Cockscorn.
3. CELOSIA (*Paniculata*) foliis lanceolato-ovatis, paniculâ diffusâ filiformi. Flor. Virg. 144. Celosia with oval spear-shaped leaves, and a slender diffused panicle. Amaranthus paniculâ flavicante gracili holoericeâ. Sloan. Hist. 1. p. 142. tab. 90.
4. CELOSIA (*Coccinea*) foliis ovatis strictis inauriculatis, caule sulcato, spicis multiplicibus cristatis. Lin. Sp. 297. Celosia with oval leaves, a furrowed stalk, and many crested spikes of flowers. Amaranthus panicula speciosa cristata. C. B. P. 121.
5. CELOSIA (*Castrensis*) foliis lanceolato-ovatis lineatis acuminatissimis, stipulis falcatis, spicis cristatis. Lin. Sp. 297. Celosia with oval, linear, spear-shaped, acute-pointed leaves, and crested spikes of flowers. Amaranthus vulgaris. Rumph. Amb. 5. p. 236.
6. CELOSIA (*Lanata*) foliis lanceolatis tomentosis obtusis, spicis confertis, staminibus lanatis. Flor. Zeyl. 102. Celosia with spear-shaped, obtuse, woolly leaves, and many spikes of flowers having downy stamina.

The first sort here mentioned, grows naturally in America, from whence I have frequently received the seeds. This rises with an upright stalk about two feet high, garnished with oval leaves ending in points, of a pale colour; those on the lower part being four or five inches long, and one and a half broad in the middle, but they diminish gradually in their size upward. Toward the upper part of the stalk, there are a few side branches sent out which stand erect; each of which is terminated by a slender spike of flowers, and the principal stalk is terminated by one which is much larger; this is two or three inches long, and about as thick as a man's middle finger, the whole spike being of a silvery colour. But there is a variety of this with slender pyramidal spikes, intermixed with red toward the top, the seeds of which I received from Dr. Linnæus, by the above title; but I am inclinable to think it is different from that which was figured by Dr. Martyn in his Decades of rare plants, which I have cultivated many years in the Chelsea garden, and have never found it to vary. The spike of this is much thicker than that of Linnæus's, and of equal size the whole length; whereas his diminishes almost to a point at the top, and the colours of both are very different. This sort is annual like the other Amaranths, and requires the same culture.

The second sort is well known by its common appellation of Cockscorn, which was given to it from the form of its crested head of flowers resembling a Cockscorn; of this there are many varieties, which differ in their form, magnitude, and colours; but as they vary from seeds, they are not enumerated as

distinct species. I have raised great varieties of these from seeds which came from China, and other countries, but have generally found them alter in a few years, notwithstanding great care has been taken in the saving of their seeds: the principal colours of their heads are red, purple, yellow, and white; but I have had some, whose heads have been variegated with two or three colours. I also raised some from seeds which I received from Persia, whose heads were divided like a plume of feathers, which were of a beautiful scarlet colour, but these in a few years degenerated: therefore I shall include all the different varieties of Cockscorn, under this general title.

The seeds of the third sort were sent me from Jamaica by the late Dr. Houstoun. This grows naturally in most of the Sugar Islands. It rises with a weak stalk near four feet high, garnished with oblong pointed leaves, which stand opposite at each joint. The flowers come out in loose panicles from the side of the stalks, and also at the end of the branches: these are divided into a great number of very slender spikes, which are of a pale yellow, shining with a gloss like silk. The plants of this perished in the autumn, without perfecting their seeds.

The fourth sort I received from China; this hath a furrowed stalk, which rises three or four feet high, garnished with oval leaves which are not eared at their base; the stalk is terminated by several spikes of flowers which are variously formed, some being crested, others are plumed like feathers, of a bright scarlet colour, so make a good appearance; but the seeds of this when carefully saved, are apt to degenerate.

The fifth sort is of humbler growth, the leaves are oval, spear-shaped, ending in very acute points; the branches proceed from the wings of the leaves, almost the length of the stalk, and are terminated by slender spikes of flowers of no great beauty, therefore the plant is preserved as a variety in the botanic gardens.

The sixth sort grows naturally in Ceylon; it rises with a very white woolly stalk from two to three feet high, garnished with obtuse, spear-shaped, woolly leaves; from the upper part of the stalk come out two or three slender side branches, which (as also the principal stalk) are terminated by woolly spikes of flowers: these flowers are so closely wrapped up in their woolly empalements, as to be scarce visible to the naked eye, so they make no appearance; but the extreme whiteness of the stalk, leaves, and spikes, make a pretty variety among other tender plants during their continuance.

This plant is tender; the seeds should be sown in the spring upon a hot-bed, and the plants should be treated in the same way as is directed for the Cockscorns; but when the plants are fully grown, they should be removed into an airy glass-case, where they may be screened from cold and wet, but have free air admitted to them in warm weather, otherwise they will not perfect their seeds in this country.

In order to have large fine Amaranths, great care should be taken in the choice of the seeds; for if they are not carefully collected, the whole expence and trouble of raising them will be lost. When you are provided with good seeds, they must be sown on a hot-bed (which should have been prepared a few days before, that the violent heat may be abated) about the beginning of March; and in about a fortnight's time (if the bed is in good temper) the plants will rise; but as they are tender when they first appear, they require great care for a few days till they get strength; first, in giving them a due proportion of air, to prevent their drawing up weak; and next to keep them from too great moisture, for a small share of moisture will cause their tender stems to rot: in sowing the seeds, there should be care taken not to put them too close, for when the plants come up in clusters, they frequently spoil each other for want of room to grow: in a fortnight or three weeks

C E L

weeks time the plants will be fit to remove, when you must prepare another hot-bed, covered with good rich light earth, about four inches thick; which should be made a few days, that it may have a proper temperature of heat; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into the new hot-bed about four inches distance every way, giving them a gentle watering to settle the earth to their roots: but in doing this, be very cautious not to bear the young plants down to the ground by hasty watering, which rarely rise again, or at least so as to recover their former strength in a long time, but very often rot in the stems, and die quite away.

After the plants are thus planted, they must be screened from the sun till they have taken fresh root; but as there is generally a great steam rising from the fermentation of the dung, which condenses to wet against the glasses, and this dropping upon the plants, very frequently destroys them; so the glasses should be frequently turned in the day-time, whenever the weather will permit; but if the weather happens to prove bad, that you cannot turn your glasses, it will be of great service to your plants, to wipe off all the moisture two or three times a day with a woollen cloth, to prevent its dropping upon the plants. When your plants are firmly rooted, and begin to grow, you must observe to give them air every day (more or less, as the weather is cold or hot) to prevent their drawing up too fast, which greatly weakens their stems.

In about a month or five weeks these plants will have grown so as to meet; therefore should have another hot-bed, which should be of a moderate temper, and covered with the same rich earth about six inches thick, in which they should be planted (observing to take them up with as much earth about their roots as possible) at seven or eight inches distance every way, giving them some water to settle the earth about their roots; but be very careful not to water them heavily, so as to bear down the plants, (as was before directed) and keep them shaded in the heat of the day, until they have taken fresh root; and be sure to refresh them often (but gently) with water, and give them air in proportion to the heat of the weather, covering the glasses with mats every night, lest the cold chill your beds, and stop the growth of the plants.

In the middle of May you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow: upon this hot-bed, you must set as many three-penny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams; then, with a trowel, or some such instrument, take up your plants (from the former hot-bed) with as much earth as possible to the roots, and place each single plant in the middle of one of the pots, filling the pot up with the earth before described, and settle it close to the root of the plant with your hands; water them gently, as before, and shade them in the heat of the day from the violence of the sun, by covering the glasses with mats; refresh them often with water, and give them a good quantity of air in the day-time.

In about three weeks more, these plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is soft and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat this as often as the weather will permit; which will harden them by degrees, to be removed abroad into the places where they are to remain the whole season: but it is not advisable to set these plants out until a week in July, observing to do it when the air is perfectly soft, and if possible, in a gentle shower of rain.

C E L

Let them at first be set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun, and strong winds, to which they must be inured by degrees: these plants, when grown to a good stature, perspire very freely, and must be every day refreshed with water, if the weather proves hot and dry; otherwise they will stunt, and never produce their plumes so fine as they would do if taken care of.

This is the proper management, in order to have fine Amaranths; which, if rightly followed, and the kinds are good, in a favourable season, will produce wonderful large fine heads, and are the greatest ornament to a good garden for upwards of two months: by this method, I have had plants five or six feet high, with crests near a foot in breadth; and I am persuaded, if the kind is good, (and there is no want of dung, or conveniencies) in a kindly season, they will grow much larger.

By the middle or latter end of September, the Amaranths will have perfected their seeds, so that you must make choice of the largest, most beautiful, and least branching plants of each kind for seed; which you should remove under shelter, (especially if the weather proves wet, or the nights frosty) that the seeds may be perfectly ripened; in the choice thereof, be sure never to take any seeds from side branches, nor from the neck of the plume, but such only as are produced in the middle thereof, which in many plants, perhaps, may be but a small quantity; but I do assure you, it is those only you can depend upon, to have your kinds good the succeeding year.

CELSIA. Lin. Gen. Plant. 675. The name was given to this plant in honour of Dr. Olaus Celsius, professor of philosophy and theology in the university of Upsal, in Sweden, by Dr. Linnæus. We have no English name for it.

The CHARACTERS are,

It hath an obtuse permanent empalement, which is as long as the petal, divided at the top into five parts. The flower is of one leaf, with a very short tube, spread open above, and cut into five unequal parts; the two upper being small, and the under larger. It hath four hairy stamina, which incline toward the upper segments of the petal, two of which are longer than the petal, and two are of the same length, terminated by small roundish summits. In the center is situated a roundish germen, supporting a slender style, crowned by an obtuse stigma. The germen afterward becomes a roundish capsule compressed at the top, sitting upon the empalement, having two cells, which are filled with small angular seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamina, and the seeds being included in a capsule.

There is but one SPECIES of this genus at present known, which is,

CELSIA (*Orientalis*) foliis duplicato-pinnatis. Hort. Cliff. 321. *Celsia* with double winged leaves. *Verbascum orientale* Sophiae folio. Tourn. Cor. 8. *Eastern Mullein* with a *Flixweed* leaf.

This plant grows naturally in Armenia, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, where they succeeded, and have been since communicated to most parts of Europe. In its natural place of growth, this is an annual; but in England it will rarely ripen its seeds, unless the plants come up in the autumn and live through the winter.

It sends out many oblong leaves, which are finely divided almost to the mid-rib on both sides; these lie flat on the surface of the ground, and from the center arises a roundish herbaceous stalk near two feet high, garnished the whole length with leaves of the same shape, but diminishing in their size gradually to the top: these are placed alternately, and at the foot-stalk of each come out the flowers, more than half the length of the stalk, which are of an iron colour on their outside, but pale yellow within, spreading

ing open like those of the common Mullein, but are not so regular; the short tube being turned downward, and the lower segments being larger than the upper, and the stamens being unequal, have occasioned Linnæus to remove it to his ringent flowers. The seed-vessel is round, compressed, and hath two cells filled with small seeds. It flowers in June, and the seeds ripen in September: if the seeds of this plant are sown upon a warm dry border as soon as they are ripe, the plants will often come up and live through the winter, provided the soil is poor; for in rich ground they are apt to grow rank, and then they are generally destroyed by the early frosts, or will rot with much wet; but if the plants should not rise the same autumn, there will be little hazard of their growing the following spring. When the plants come up, they will require no other care but to keep them clean from weeds, and thin them if they are too close; for they do not bear removing well, so should be sown where they are intended to remain.

I have sometimes, when the seasons have proved warm, had ripe seeds from plants sown in the spring; but this cannot be depended on, therefore it is much better to sow the seeds in autumn.

CELTIS. Tourn. Inst. R. H. 612. tab. 383. Lin. Gen. Plant. 1012. The Lote or Nettle-tree, in French Micocoulier.

The CHARACTERS are,

It hath male and hermaphrodite flowers on the same tree: the hermaphrodite flowers are single, and situated above the male. The empalement of the hermaphrodite flower is divided into five parts, in which there are no petals, but five short stamens terminated by thick quadrangular summits, which have four furrows. In the center is situated an oval germen, supporting two reflexed styles crowned by a single stigma. The germen afterward becomes a round berry with one cell, inclosing a roundish nut. The male flowers have their empalements divided into six parts, and have no germen or style, but in other parts like the hermaphrodite.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, intitled Polygamia Monœcia, from the same tree having male and hermaphrodite flowers.

The SPECIES are,

1. CELTIS (*Australis*) foliis lanceolatis acuminatis, serratis, nervosis. Nettle-tree with spear-shaped pointed leaves, which are veined and sawed on their edges. Celtis fructu nigricante. Tourn. Inst. 612. Lote-tree with a black fruit.
2. CELTIS (*Occidentalis*) foliis oblique-ovatis, serratis, acuminatis. Lin. Sp. Plant. 1044. Nettle-tree with oblique, oval, pointed leaves, which are sawed on their edges. Celtis fructu obscure purpurascens. Inst. R. H. 612. Lote-tree with a dark purple fruit.
3. CELTIS (*Orientalis*) foliis ovato-cordatis, denticulatis, petiolis brevibus. Nettle-tree with oval heart-shaped leaves, slightly indented, and short foot-stalks. Celtis orientalis minor, foliis minoribus & crassioribus, fructu flavo. Inst. Cor. 42. Smaller Eastern Lote-tree with smaller and thicker leaves, and a yellow fruit.
4. CELTIS (*Americana*) foliis oblongo-ovatis, obtusis, nervosis, superne glabris, subtus aureis. Nettle-tree with oblong, obtuse, nervous leaves, which are smooth on their upper surface, and of a gold colour beneath. Celtis foliis citrii subtus aureo, fructu rubro. Plum. Cat. 18. Lote-tree with Citron leaves, of a gold colour on their under side, and a red fruit.

The first sort grows naturally in the south of France, in Spain and Italy, where it is one of the largest trees of those countries: yet this is not so plenty in England as the second, nor do I remember to have seen but two large trees of this sort in the English gardens; one of which was formerly growing in the Bishop of London's garden at Fulham, but was cut down some years past, with many other curious exotic trees, which were there growing in great perfection: the other was in the garden of Dr. Uvedale at Enfield, which was there standing a few years ago, when I paid a visit to that place, which had frequently pro-

duced fruit, but was never propagated in this country; nor were there any young plants of this kind in the garden, till about fourteen years ago, when I procured a good quantity of the fruit from Italy, which I communicated to several of my friends.

This tree rises with an upright stem to the height of forty or fifty feet, sending out many slender branches upward, which have a smooth dark coloured bark, with some spots of gray; these are garnished with leaves placed alternately, which are near four inches long, and about two broad in the middle, ending in long sharp points, and deeply sawed on their edges, having several transverse veins which are prominent on their under side. The flowers come out from the wings of the leaves all along the branches; they have a male and an hermaphrodite flower generally at the same place, the male flowers being situated above the others: these have no petals but a green herbaceous empalement, so make no figure; they come out in the spring, at the same time when the leaves make their first appearance, and generally decay before the leaves have grown to half their magnitude. After the flowers are past, the germen of the hermaphrodite flowers become a round berry about the size of a large Pea, which, when ripe, is black.

The second sort grows naturally in North America; it delights in moist rich soil, in which it becomes a very large tree. This rises with a strait stem, which in young trees is smooth and of a dark colour, but as they advance, it becomes rougher and of a lighter green. The branches are much diffused on every side, and are garnished with oblique oval leaves, ending in points, sawed on their edges; they are placed alternately on the branches, with pretty long foot-stalks. The flowers come out opposite to the leaves, upon pretty long foot-stalks; the male flowers standing above the hermaphrodite as in the other species; after these decay, the hermaphrodite flowers are succeeded by roundish berries, which are smaller than those of the first sort, and when ripe, are of a dark purple colour. This tree flowers in May, and the seeds ripen in October. Of this sort there are several pretty large trees in the English gardens, some of which produce great quantities of fruit annually, which in favourable seasons come to maturity, so that from these seeds there have been plants raised; and there are few years, in which there is not fruit of this sort sent from America, whereby it is now become pretty common in the English nurseries.

This tree is late in coming out in the spring, but in recompense for that, it continues as long in beauty in the autumn, for it is the latest in fading of any of the deciduous trees; nor do the leaves alter their colour long before they fall, but continue in full verdure till within a few days of their dropping off; and, so soon as they begin to fall, the trees will in a few days be quite destitute of leaves, so that the litter which their falling leaves occasion, may be sooner cleared away, than that of any other deciduous tree. There is little beauty in the flowers or fruit of this tree; but, as the branches are well clothed with leaves, which are of a fine green colour, the trees, when mixed with others in wildernesses, make a pleasing variety during the summer season. The wood of this tree being tough and pliable, is esteemed by coachmakers for the frames of their carriages.

The third sort was discovered by Dr. Tournefort in Armenia, from whence he sent the fruit to the royal garden at Paris, where they succeeded, and the trees, which were there raised, have produced fruit for several years, so that most of the curious gardens in Europe have been furnished with it from thence.

It rises with a stem about ten or twelve feet high, dividing into many branches, which spread horizontally on every side, having a smooth greenish bark, garnished with leaves about an inch and a half long, and near an inch broad, inclining to a heart-shape, but

but are oblique, one of the ears of the base being smaller and lower than the other; they are of a thicker texture than those of the common sort, and of a paler green, placed alternate on the branches, and have short foot-stalks. The flowers come out from the foot-stalks of the leaves, in the same manner as the former, and are succeeded by oval yellow berries, which, when fully ripe, turn of a darker colour. The wood of this tree is very white.

These trees are all propagated by seeds, which should be sown soon after they are ripe, when they can be procured at that season, for these frequently come up the following spring; whereas, those which are sown in the spring, will not come up till a twelvemonth after: therefore it is the best way to sow them in pots or tubs, that they may be easily removed, for those which are sown in the spring should be placed in a shady situation in summer, and constantly kept clean from weeds; but in autumn they should be placed in a warm situation, plunging the pots into the ground; and if they are covered over with a little tan from a decayed hot-bed, it will prevent the frost from penetrating the earth to injure the seeds; and if these pots are placed on a gentle hot-bed in the spring, it will greatly forward the vegetation of the seeds, whereby the plants will have more time to get strength before the winter: but when the plants appear above ground they must have a large share of air admitted to them, otherwise they will draw up weak; and as soon as the weather is warm, they must be exposed to the open air, and in summer they must be constantly kept clean from weeds; if the season proves dry, they will require water two or three times a week. In autumn it will be proper to remove the pots, and place them under a hot-bed frame, to shelter them in winter from severe frost; or where there is not that conveniency, the pots should be plunged into the ground near a wall or hedge; and as the plants, when young, are full of sap, and tender, the early frosts in autumn frequently kill the upper part of the shoots; therefore the plants should be either covered with mats, or a little straw or Pease-haulm laid over them to protect them.

In the following spring the plants should be taken out of the seed-pots, and planted in the full ground: this should be done about the middle or latter end of March, when the danger of the frost is over; therefore a bed or two should be prepared (according to the number of plants raised) in a sheltered situation, and, if possible, in a gentle loamy soil. The ground must be well trenched, and cleared from the roots of bad weeds, and when levelled, should be marked out in lines at one foot distance; then the plants should be carefully turned out of the pots and separated, so as not to tear their roots, and planted in the lines at six inches asunder, pressing the earth down close to the roots. If the ground is very dry when they are planted, and there is no appearance of rain soon, it will be proper to water the beds, to settle the ground to the roots of the plants; and after this, if the surface of the ground is covered with some old tan or rotten dung, it will keep it moist, and prevent the drying winds from penetrating to the roots of the plants.

The following summer, the necessary care must be to keep them constantly clean from weeds; but after the plants are pretty well established in the ground, they will not require any water, especially toward the latter end of summer, for that will occasion their late growth, whereby they will be in great danger of suffering by the autumn frosts; for the more any of these young trees are stopped in their growth by drought towards autumn, the firmer will be their texture, so better able to bear the cold.

The plants may remain in these nursery-beds two years, by which time they will have obtained sufficient strength to be transplanted where they are designed to remain for good, because these plants extend their roots wide every way; so that if they stand long in the nursery, their roots will be cut in

removing, which will be a great prejudice to their future growth.

These sorts are hardy enough to thrive in the open air in England, after they are become strong; but for the two first winters after they come up from seeds, they require a little protection, especially the third sort, which is tenderer than either of the former. The young plants of this sort frequently have variegated leaves, but those are more impatient of cold than the plain leaved.

The fourth sort was first discovered by father Plumier, in the French islands of America; and it was found growing in Jamaica, by Dr. Houstoun, who sent the seeds to England. This rises with a strait trunk near twenty feet high, covered with a gray bark, divided into many branches upward, garnished with leaves near four inches long, and two and a half broad, rounded at their extremity, of a thick texture, very smooth on their upper surface, and on their under side are of a lucid gold colour, placed alternately on the branches. The fruit is round and red, but the flowers I have not seen.

The seeds of this sort rarely come up the first year, so they may be sowed in pots, and plunged into the tan-bed in the stove, where they should remain till the plants come up. These plants must be constantly kept in the bark-stove, and treated in the same manner as other tender exotics.

CENTAUREA. Lin. Gen. Plant. 880. Centaurium majus. Tourn. Inst. R. H. 449. tab. 256. Jacea. Tourn. 443. Cyanus. Tourn. 445. Greater Centaury, Knapweed, Blue Blottle, &c.

The CHARACTERS are,

It hath a compound flower, whose disk is composed of many hermaphrodite florets, and the borders or rays of female florets, which are larger and looser; these are included in a common, roundish, scaly empalement; the hermaphrodite florets have narrow tubes, swelling at the top, and cut into five parts; these have five short hairy stamina, terminated by cylindrical summits: the germen is situated under the petal, supporting a slender style, crowned with an obtuse stigma. The germen afterward becomes a single seed shut up in the empalement. The female florets have a slender tube, but expands above, where it is enlarged, and cut into five unequal parts; these are barren.

This genus of plants is ranged in the third section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Frustranea; the flowers of this section have their disk and middle composed of hermaphrodite florets, which are fruitful, and their borders of female abortive florets.

The SPECIES are,

1. CENTAUREA (*Alpina*) calycibus inermibus, squamis ovatis obtusis, foliis pinnatis glabris integerrimis impari serrato. Hort. Cliff. 421. *Centaury with an empalement without spines, oval obtuse scales, and smooth winged leaves, which are entire.* Centaurium alpinum luteum. C. B. P. 117. *Yellow Alpine Centaury.*
2. CENTAUREA (*Centaurium*) calycibus inermibus, squamis ovatis, foliis pinnatis, foliolis serratis decurrentibus. Hort. Cliff. 421. *Centaury with an empalement without spines, oval scales, and winged leaves, whose lobes are sawed, and run along the midrib.* Centaurium majus, folio in lacinias plures diviso. C. B. P. 117. *Greater Centaury with a leaf divided into many parts.*
3. CENTAUREA (*Glaucifolia*) calycibus scariosis foliis indivisis integerrimis decurrentibus. Hort. Cliff. 421. *Centaury with a scaly empalement, and undivided entire leaves running along the stalks.* Centaurium majus orientale erectum, glauci folio, flore luteo. Tourn. Cor. 32. Com. Rar. Plant. 39. *Upright, eastern, greater Centaury, with a Wood leaf and a yellow flower.*
4. CENTAUREA (*Stæbe*) calycibus ciliatis oblongis, foliis pinnatifidis linearibus integerrimis. Prod. Leyd. 140. *Centaury with oblong hairy empalements, and winged pointed leaves, which are very narrow and entire.* Stæbe incana, cyano similis tenuifolia. C. B. P. *Hoary Stæbe with the appearance of Blue Bottle, and a narrow leaf.*

5. **CENTAUREA** (*Conifera*) calycibus scariosis, foliis tomentosis, radicalibus lanceolatis, caulinis pinnatifidis caule simplici. Prod. Leyd. 142. *Centauray with a scaly empalement, woolly leaves, those near the root being spear-shaped, those on the stalk pointed, and a single stalk.* *Centaureum majus incanum, humile, capite pini.* Tourn. Inst. R. H. 469. *Dwarf, hoary, greater Centaury, with a head like a Pine cone.*
6. **CENTAUREA** (*Montana*) calycibus ferratis, foliis lanceolatis decurrentibus, caule simplicissimo. Hort. Cliff. 422. *Centauray with sawed empalements, spear-shaped running leaves, and a single stalk.* *Cyanus montanus latifolius.* sc. *Verbasculum Cyanoides.* C. B. P. 273. *Greater Mountain Blue Bottle with broad leaves.*
7. **CENTAUREA** (*Angustifolia*) calycibus ferratis, foliis lineari-lanceolatis decurrentibus, caule simplici. *Centauray with sawed empalements, very narrow, spear-shaped, running leaves, and a single foot-stalk.* *Cyanus angustiore folio & longiore Belgicus.* H. R. Par. *Narrower and longer leaved Belgick Blue Bottle.*
8. **CENTAUREA** (*Moschata*) calycibus inermibus, subrotundis glabris, squamis ovatis, foliis lyrato-dentatis. Hort. Cliff. 421. *Centauray with unarmed, roundish, smooth empalements, oval scales, and sinuated leaves.* *Cyanus floridus odoratus, Turcicus five orientalis major.* Park. Theat. 421. *Sweet oriental Cyanus, commonly called Sweet Sultan.*
9. **CENTAUREA** (*Amberboi*) calycibus inermibus, subrotundis, glabris, squamis ovatis obtusis, foliis laciniatis ferratis. *Centauray with roundish, smooth, unarmed empalements, oval obtuse scales, and cut leaves, which are sawed on their edges.* *Cyanus orientalis flore luteo fistuloso.* Ac. R. Par. 75. *Eastern Cyanus with a yellow fistular flower, commonly called yellow Sweet Sultan.*
10. **CENTAUREA** (*Cyanus*) calycibus ferratis, foliis linearibus integerrimis, infimis dentatis. Hort. Cliff. 422. *Centauray with sawed empalements, very narrow entire leaves indented below.* *Cyanus fegetum.* C. B. P. 273. *Corn Blue Bottle.*
11. **CENTAUREA** (*Lippii*) calycibus inermibus, squamis mucronatis, foliis pinnatifidis obtusis decurrentibus. Lin. Sp. Plant. 910. *Centauray with unarmed empalements, having pointed scales, and winged pointed leaves, which are obtuse, running along the stalk.* *Cyanus Ægypticus flore parvo purpureo, caule alato.* D. Lipp. *Egyptian Cyanus with a small purple flower, and a winged stalk.*
12. **CENTAUREA** (*Cineraria*) calycibus ciliatis terminalifessilibus, foliis tomentosis pinnatifidis, lobis acutis. Hort. Cliff. 422. *Centauray with hairy empalements closely terminating the stalks, woolly leaves with winged points, and the segments very narrow.* *Jacea montana candidissima, Stæbes foliis.* C. B. P. 273. *White Mountain Knapweed with a Stæbe leaf.*
13. **CENTAUREA** (*Ragulina*) calycibus ciliatis, foliis tomentosis pinnatifidis, foliolis obtusis ovatis integerrimis exterioribus majoribus. Hort. Cliff. 422. *Centauray with hairy empalements, woolly leaves with winged points, the small leaves oval and obtuse, the outer larger.* *Jacea arborea argentea Ragulina.* Zan. Hist. 107. *Silvery-tree Knapweed of Ragusa.*
14. **CENTAUREA** (*Napifolia*) calycibus palmato-spinosis, foliis decurrentibus radicalibus lyratis. Prod. Leyd. 141. *Centauray with palmated spinous empalements, and sinuated prickly leaves running along the stalks.* *Jacea cyanoides altera, alato caule.* Herm. Par. 189. *Another Knapweed like Cyanus, with a winged stalk.*
15. **CENTAUREA** (*Rhaponica*) calycibus scariosis, foliis ovato-oblongis denticulatis integris petiolatis, subtus tomentosis. Hort. Cliff. 421. *Centauray with scaly empalements, oval, oblong, indented, entire leaves, having foot-stalks, woolly underneath.* *Centaureum majus, folio helenii incano.* Tourn. Inst. 449. *Greater Centaury with a white Elecampane leaf.*
16. **CENTAUREA** (*Peregrina*) calycibus setaceo-spinosis, foliis lanceolatis petiolatis, inferne dentatis. Hort. Cliff. 423. *Centauray with bristly prickly empalements, spear-shaped leaves, with foot-stalks indented beneath.* *Centaureum majus folio molli acuto laciniato, flore aureo magno, calyce spinoso.* Boërh. Ind. alt. 1. p.

144. *Greater Centaury with a soft, pointed, cut leaf, and a large golden flower, with a prickly empalement.*
17. **CENTAUREA** (*Orientalis*) calycibus squamato-ciliatis, foliis pinnatifidis, pinnis lanceolatis. Lin. Sp. Plant. 913. *Centauray with hairy scales to the empalement, wing-pointed leaves, whose lobes are spear-shaped.* *Cyanus foliis radicalibus partim integris, partim pinnatis, bractea calycis ovali, flore sulphureo.* Hall. Act. Phil. 1745.
18. **CENTAUREA** (*Argentea*) calycibus ferratis, foliis tomentosis, radicalibus pinnatis, foliolis uniauritis. Lin. Sp. 1290. *Centauray with sawed empalements, woolly leaves, those near the root winged, and the lobes eared.* *Jacea Cretica laciniata argentea, flore parvo flavescente.* Tourn. Cor. 31.
19. **CENTAUREA** (*Sempervirens*) calycibus ciliatis, foliis lanceolatis ferratis, inferioribus hastatis. Lin. Sp. 1291. *Centauray with a hairy empalement, spear-shaped sawed leaves, and those near the root halbert-shaped.* *Jacea Lusitanica sempervirens.*
20. **CENTAUREA** (*Splendens*) calycibus scariosis obtusis, foliis radicalibus pinnatifidis, caulinis pinnatis denticulatis lanceolatis. Prod. Leyd. 142. *Centauray with a rough obtuse empalement, the radical leaves wing-pointed, and those on the stalk winged, spear-shaped, and indented.* *Jacea caliculis argenteis major.* Inst. R. H. 444.
21. **CENTAUREA** (*Romana*) calycibus palmato-spinosis, foliis decurrentibus inermibus, radicalibus pinnatifidis, impari maximo. Hort. Cliff. 423. *Centauray with a palmated spiny empalement, smooth running leaves, those near the root wing-pointed, and a large terminating lobe.* *Jacea spinosa Cretica.* Zan. Hist. 141.
22. **CENTAUREA** (*Sphaerocephala*) calycibus palmato-spinosis, foliis ovato-lanceolatis petiolatis dentatis. Hort. Cliff. 423. *Centauray with a palmated prickly empalement, and oval, spear-shaped, indented leaves, having foot-stalks.* *Jacea sphaerocephala spinosa Tingitana.* H. L. 332.
23. **CENTAUREA** (*Eriophora*) calycibus duplicato-spinosis lanatis, foliis semidecurrentibus integris sinuatisque caule prolifero. Hort. Upsal. 272. *Centauray whose empalement is downy and doubly armed with spines, running leaves, some entire, others sinuated, and a childing stalk.*
24. **CENTAUREA** (*Benedicta*) calycibus duplicato-spinosis lanatis involucriatis, foliis semidecurrentibus denticulato-spinosis. Lin. Sp. 1296. *Centauray whose empalement is downy and doubly armed with spines, running leaves with indentures, terminating in spines.* *Carduus Benedictus.* Camer. Epit. 562. *Blessed Thistle.*
- There are many other species of this genus, which are preserved in botanic gardens for the sake of variety; some of which grow naturally in England, and are often troublesome weeds in the fields, so do not deserve a place in gardens; therefore I chose not to trouble the reader with mentioning their titles, but have here selected those species which have some beauty to recommend them.
- The first sort grows naturally upon the Alps. This hath a perennial root, which strikes deep into the ground, sending out a great number of long, winged, smooth leaves, of a glaucous colour; the stalks rise near four feet high, and divide upward into many branches, garnished with small leaves of the same form as the lower; each of these stalks is terminated by a single head of yellow flowers, composed of many florets; those which occupy the disk are hermaphrodite, but those of the ray are female. This flowers in June and July, and, in dry seasons, will perfect their seeds in autumn. It may be propagated either by seeds, or by parting their roots in the autumn, being careful not to divide the roots too small. The seeds should be sown in the spring on a bed of light earth; and when the plants are fit to remove, they should be transplanted into a bed of fresh earth six inches asunder, in which place they should remain till autumn, when they should be planted where they are designed to remain.
- The second sort stands in the list of medicinal plants of the college, but is very rarely used; the root is reckoned

reckoned to be binding, and good for all kinds of fluxes, and of great use to heal wounds. This grows naturally on the mountains of Italy and Spain; it hath a strong perennial root like the former sort, from which come out a great number of long winged leaves, which spread wide on every side, of a lucid green, and sawed on their edges; the flower-stalks are slender, but very stiff, and divide upward into many smaller foot-stalks; these, together with the other stalks, rise five or six feet high, having at each joint one small winged leaf, of the same form with the other: each of these foot-stalks is terminated by a single head of purplish flowers, which are considerably longer than the empalement. This sort flowers in July, and in very warm dry seasons will produce ripe seeds in England. It may be propagated by parting of the roots in the same manner as the former sort, and the plants must be treated in the same way, but should have more room to grow, therefore it is not proper for small gardens; but in large open borders, or to intermix in open quarters with other tall growing plants, this will make a variety.

The third sort was discovered by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris, and from thence it hath since been communicated to most of the curious gardens in Europe. This hath a perennial root, which strikes deep into the ground, from which springs up a great tuft of long entire leaves, shaped like those of Woad, growing upright, with many upright stalks, which grow near five feet high, garnished with leaves coming out single at each joint, of the same shape as the under, but are less, and have a border or wing running along the stalk. The upper part of the stalk divides into two or three smaller, each of which is terminated by a single head of yellow flowers, included in a silvery scaly empalement. This flowers in July, but rarely produces good seeds in England. It may be propagated by parting the roots in the same manner as the former, and the plants may be treated in the same way, being equally hardy; and as this doth not spread so much as the last, it may be allowed a place in smaller gardens.

The fourth sort grows naturally in Austria. This hath a perennial root as the former, from which come out many winged leaves, which are hoary, the segments narrow and entire; the stalks rise near three feet high, dividing into several branches, which have a single winged leaf at each joint, of the same shape with the other; at the end of each stalk is one head of purple flowers, inclosed in an oblong scaly empalement, each scale being bordered with small hairs like an eye-brow. The flowers appear in June, and the seeds ripen in August. This is propagated by seeds, which may be sown in a bed of common earth, in a nursery; and when the plants come up they must be thinned, and kept clean from weeds, and the following autumn the plants may be transplanted where they are designed to remain; after which they will require no further care. Two or three of these plants may be allowed a place in gardens where there is room, for the sake of variety.

The fifth sort grows naturally in the south of France, and in Italy: I received the seeds of this from Verona. It hath a perennial root, which doth not divide and spread as the former, but grows single, sending out in the spring several entire spear-shaped leaves, and afterward a single stalk, more than a foot high, garnished at each joint with one divided hoary leaf; and at the top comes out a single, large, scaly head, shaped like a cone of the Pine-tree, very taper at the top, where it closely surrounds the florets, whose tops just peep out of the empalement: they are of a bright purple colour, and appear in June, but are not succeeded by seeds in England, so cannot be propagated unless the seeds are procured from abroad. These seeds may be sown, and the plants afterward treated in the same manner as the last.

The sixth sort is the common perennial Blue Bottle, which by some is titled Batchelors Button. This is

so well known as to need no description; the roots of this sort creep under ground to a great distance, whereby the plant propagates too fast, and often becomes troublesome in gardens. It flowers in May and June, and will grow in any soil and situation.

The seventh sort differs from the eighth, in having much longer and narrower leaves, which are not so white, the heads of flowers are also smaller; but whether this is only a variety from the other, I cannot determine, having never raised either from seeds; for these plants spread very much by their creeping roots, which renders them barren, as is frequently the case with many other creeping rooted plants, few of which produce seeds: however, this plant has always retained its difference from the year 1727, when I first brought it to England; and as it propagates so fast, it is now become almost as plenty in the gardens, as the common broad leaved sort. This is equally hardy, and may be planted in any soil or situation, where many other sorts will not thrive, and during its continuance in flower will make a variety in the garden.

The eighth sort is annual, so is only propagated by seeds. This has been many years propagated in the English gardens, under the title of Sultan Flower, or Sweet Sultan. It was brought from the Levant, where it grows naturally in arable land among the corn. This sends up a round channelled stalk near three feet high, which divides into many branches, garnished with jagged leaves, of a pale green, smooth, and stand close to the branches; from the side of the branches come out long naked foot-stalks, each sustaining a single head of flowers shaped like those of the other species, which have a very strong odour, so as to be offensive to many people, but to others is very grateful. The empalement of these is scaly, round, and without spines; the flowers are in some purple, and others white, and likewise a flesh colour between them hath come from the same seeds. There is also a variety of this with fistular flowers, and another with fringed flowers, commonly called Amberboi or Emberboi: but these have degenerated to the common sort in a few years, although I have saved the seeds with great care, so I suppose they are only varieties. These seeds are commonly sown upon a hot-bed in the spring, to bring the plants forward, and in May they are transplanted into the borders of the flower-garden; but if the seeds are sown in a warm border in autumn, they will live through the winter; and these plants may be removed in the spring into the flower-garden, which will be stronger, and come earlier to flower than those which are raised in the spring. The seeds may also be sown in the spring on a common warm border, where the plants will rise very well, but these will be later in flowering than either of the other. The autumnal plants will begin to flower the middle of June, and will continue flowering till September; and the spring plants will flower a month later, and continue till the frost stops them. Their seeds ripen in autumn.

The ninth sort has been supposed to be only a variety of the former, which is a great mistake; for although there is a great similitude in their appearance, yet they are specifically different, so never alter. I have cultivated this sort upward of forty years, and have never observed the least variation in it. This is much tenderer than the former, so the seeds must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted on a fresh hot-bed to bring them forward: when they have taken root in this bed, they must have air admitted to them every day, to prevent their drawing up weak, and refreshed with water sparingly, because they are very apt to rot with much wet. When the plants have obtained strength, they must be carefully taken up, and planted in separate pots filled with light earth, and some of them placed in the shade till they have taken root; then they may be placed with other annual plants in the pleasure-garden, where they will continue long in beauty. But as these plants which are

are placed in the open air rarely produce good seeds, there should be two or three plants kept in a moderate hot-bed under a deep frame, where they will come earlier to flower; and being protected from wet and cold, they will ripen their seeds every year, which is the surest method to preserve the sort.

This sort differs from the common, in its leaves being sawed on their edges; the flowers are fistular, of a bright colour, and have a very agreeable soft odour. It flowers in July and August, and the seeds ripen in October.

The tenth sort is the common Blue Bottle, which grows naturally amongst the corn in most parts of England: this stands in the list of medicinal plants. There is a distilled water of the flowers, which is esteemed good for the eyes. There are great varieties of colours in these flowers, some of which are finely variegated: the seeds of these are sold by seedsmen, by the title of Bottles of all Colours. These are annual plants, which will rise in any common border, and require no other care but to keep them clean from weeds, and thinned where they are too close, for they do not thrive well when they are transplanted. If the seeds are sown in autumn, they will succeed better, and the plants will flower stronger than those which are sown in the spring.

The seeds of the eleventh sort were sent me by Dr. Jussieu, from Paris, who received them from Dr. Lippi, at Grand Cairo. This is an annual plant, which rises near two feet high, sending out two or three branches toward the top; the leaves are divided into many obtuse segments, and have a border running along the stalk; the flowers are small, of a bright purple, and have a scaly empalement. If the seeds are sown in the spring upon a border of light earth, where the plants are to remain, they will require no farther care but to keep them clean from weeds. It flowers in July, and the seeds ripen in autumn.

The twelfth sort is a perennial plant, which retains its leaves through the year. This grows naturally in Italy, on the borders of the fields. The leaves are hoary, and divided into many narrow segments; the stalks rise near three feet high, branching upward into many divisions, each being terminated by a head of purple flowers; these come out in June, and in favourable seasons will perfect their seeds in autumn. This sort will live abroad in moderate winters, if it has a warm situation and a dry soil; but in severe winters the plants are commonly killed, so one or two of them may be sheltered under a common frame in winter to preserve the kind. It may be easily propagated by seeds in the same manner as the fourth sort; or if the young branches, which do not shoot up to flower, are cut off, and planted in a shady border any time in summer, they will take root, and in autumn may be removed to warm borders, or put into pots to be sheltered in winter.

The thirteenth sort grows naturally in Mauritania, and in several other places on the borders of the Mediterranean Sea. This seldom rises more than three feet high in this country; it hath a perennial stalk, which divides into many branches, garnished with very white woolly leaves, divided into many obtuse entire lobes, the small leaves or lobes on the exterior part of the leaf being the largest. The flowers are produced from the side branches upon short foot-stalks, which are of a bright yellow; and are included in a fine hairy empalement. These appear in June and July, but scarce ever are succeeded by seeds in England. It is propagated by planting of the young shoots in the same manner as the last, and the plants require protection from hard frost. But if they are planted in dry lime-rubbish, where they will not grow luxuriant, they will resist the cold of our ordinary winters in the open air. As this plant retains its leaves all the year, which are extremely white, it makes a pretty variety in a garden.

The fourteenth sort is annual. This grows naturally in the Archipelago. It rises with a branching stalk

about three feet high; the lower leaves are not much unlike those of the Turnep, being rounded at their ends, and their base is cut into many segments; those upon the stalks and branches are nearly of the same form, but diminish gradually in their size to the top; these have a border or wing running along the stalks, which connect them together; the flowers are produced at the end of the branches, which have prickly empalements; the spines come out from the border of the scales, divided like the fingers of a hand. The flowers are of a bright purple, so make a pretty appearance. This sort may be treated in the same manner as the Corn Bottle, by sowing the seeds in autumn, and keeping the plants clean from weeds. The plants will flower in June, and the seeds will ripen in August. If some seeds are also sown in the spring, the plants will come to flower a month after the others, and will continue flowering till the frost stops them. But these plants do not always perfect seeds, so that from the autumnal plants the seeds will more certainly be procured.

The fifteenth sort grows naturally upon the Helvetician, and some of the Italian mountains: I received the seeds of this sort from Verona: it hath a perennial root and an annual stalk; the leaves are oblong, slightly indented on their edges, and woolly on their under side; these have much the resemblance of those of Elecampane, generally standing upright; the stalks rise little more than a foot high, and are terminated by large single heads of purple flowers, inclosed in scaly empalements; these appear in July, but unless the season proves very dry and warm they have no seeds succeed them in this country; so that this, like the fifth sort, is very difficult to propagate in England, unless good seeds can be procured from the countries where they naturally grow. This is very hardy, so may be treated in the same manner as any of the former perennial sorts; but will require a little more room than the fifth.

The sixteenth sort grows naturally in Austria and Hungary, from both which countries I have received the seeds. The lower leaves of this plant spread flat on the ground; they are soft, hairy, and end in sharp points, but toward their base are cut into several narrow segments; the stalks rise near three feet high, garnished at each joint by spear-shaped entire leaves, and are terminated by single large heads of flowers, of a gold colour, inclosed in a prickly scaly empalement. This flowers in July and August, but never produces seeds in this country. It hath a perennial root, which sends out offsets; these may be taken from the old plants in autumn, whereby it may be easily propagated. It is very hardy in respect to cold, but should have a dry soil, the roots being very apt to rot in winter with much wet.

The seventeenth sort grows naturally in Siberia. The seeds of this were sent me from Petersburg. This sends out many long winged leaves from the root, which are divided into several spear-shaped lobes; the stalks rise near five feet high, and divide upward into many smaller branches, garnished with leaves of the same form as the lower, but much smaller; and the segments very narrow; each of the stalks is terminated by a head of yellow flowers, inclosed in a scaly empalement; the borders of the scales are set with fine hairs like an eye-brow. It flowers in June, July, and August, and the seeds ripen in autumn. This hath a perennial root and an annual stalk, which, with the leaves, decay in autumn; and arise new from the root in the spring. It may be propagated either by seeds or parting of the roots, in the same manner as the fifth sort; and the plants require a large share of room, so should not be planted too near other plants; therefore it is not proper furniture for small gardens.

The eighteenth sort grows naturally in Crete. This hath a perennial root; the lower leaves are winged and very woolly, those on the flower-stalks are single, wedge-shaped, and indented; the stalks are terminated by heads of yellow flowers, composed of as many florets

C E P

florets as the other sorts. This flowers in July, but rarely produces ripe seeds in this country, so is propagated by slips as the fifth sort; and as the plants which are exposed to the open air in winter are frequently destroyed, it will be proper to place one or two of them under a common frame to preserve the species.

The nineteenth sort grows naturally in Portugal: the stalks of this are perennial; the leaves continue in verdure through the year, for which it is chiefly valued, for the flower has little more beauty than the common Knapweed. It flowers in June and July, and in warm seasons the seeds ripen in September. It is propagated by seeds, which, if sown in April in a bed of light earth, the plants will rise easily. These plants, in a dry soil and a sheltered situation, will live in the open air in mild winters; but as they are frequently killed when the frosts are severe, it will be proper to shelter a plant or two under a common frame in winter to preserve the species.

The twentieth sort grows naturally in Spain, and upon the Helvetian mountains. This rarely continues longer than two or three years: the lower leaves are doubly wing-pointed, those on the stalks are spear-shaped, winged, and indented; the stalks rise three feet high, and are terminated by flowers like those of the common Knapweed, having silvery empalements. It flowers in July, and the seeds ripen in September. If these are sown in April on a bed of light earth, the plants will come up, and will live through the winter in the open air.

The twenty-first sort grows naturally in the Campania of Rome. This is a biennial plant in England; those plants which arise from seeds in the spring seldom flower till the following year, and when they perfect their seeds they die. The stalks of this sort rise three feet high; the lower leaves are wing-pointed, without spines; those on the stalks run along the stalks like wings; the flowers are large, red, and their empalements are strongly armed with spines. This flowers in July, and the seeds ripen in September. It may be propagated by seeds as the former.

The second sort grows naturally in Spain and Mauritania. This is an annual plant, which rarely ripens its seeds in England; the leaves of this are spear-shaped, indented, and woolly; the stalk rises two feet high, dividing upward into three or four branches, which are terminated by pretty large heads of flowers, whose empalements are woolly, and strongly armed with spines. This flowers in July, and in warm seasons the seeds ripen in September. It is propagated by seeds as the two former sorts.

The twenty-third sort grows naturally in Portugal. The stalk of this rises two feet high, garnished with woolly leaves; some of which are entire, others are sinuated on their borders; the stalks are terminated by woolly heads of flowers, strongly armed with double spines on the empalement, which almost incloses the florets. It flowers in July, and in warm seasons the seeds ripen in September. It is propagated by seeds as the former.

The twenty-fourth sort is the *Carduus Benedictus*, or Blessed Thistle, which is frequently used as an emetic. It grows naturally in Spain and the Levant; in England it is propagated in gardens for medicinal use. It is an annual plant, which perishes soon after the seeds are ripe. The surest method of cultivating this plant, is to sow the seeds in autumn; and when the plants come up, to hoe the ground, to cut up the weeds, and thin the plants; and in the following spring to hoe it a second time, leaving the plants a foot asunder, which will ripen their seeds in autumn, and soon after decay.

CENTAURIUM MINUS. See **GENTIANA**.

CENTINODIUM, Knot Grass. See **POLYGONUM**.

CEPA, the Onion.

The botanical characters of this genus are the same with those of *Allium*, to which it is now joined by the late system; but as this work is intended for the instruction of such as are not well acquainted with the

C E P

science of botany, or who may have no inclination to study it, and yet may want information how to cultivate the plants which are useful in the kitchen, I have chosen to treat of these under their former appellation. Mr. Ray and Tournefort admit of the fistular leaves and swelling stalks, as characters to distinguish the plants of this genus from *Porrum* and *Allium*.

The VARIETIES of the common Onion are,

The Strasburgh. *Cepa oblong*. C. B. P. 71.

The Spanish Onion. *Cepa vulgaris*, floribus & tunicis purpurascens. C. B. P. 71.

The white Egyptian Onion. *Cepa floribus & tunicis candidis*. C. B. P. 71.

All these vary from seeds, so that there are several intermediate differences which are not worth enumerating.

These three varieties are propagated by seeds, which should be sown at the latter end of February or the beginning of March, on good, rich, light ground, which should be well dug and levelled, and cleared from the roots of all bad weeds; then the seeds should be sown in a dry time, when the surface of the ground is not moist; and where they are intended for a winter crop, they must not be sown too thick. The common allowance of seed is six pounds to an acre of land; but the generality of gardeners sow more, because many of them allow for a crop to draw out, which they call cullings; these are all such as want to be removed from others, so are thinned out when young, and tied in bunches for the market; but those who have regard to their principal crop, never practise this; therefore sow no more seeds than is sufficient, which is the quantity before-mentioned, for when the plants come up too close, they draw each other weak; and when this happens, their roots never grow so large as those which are thin: besides, there is a greater trouble in hoeing them; and when they are thinned for the market, the ground is trodden over, and the Onions which are to stand have their leaves bruised, whereby they are greatly injured; so that where young Onions are wanted, it is a much better way to sow some separate beds for this purpose, than to injure the future crop.

In about six or seven weeks after sowing, the Onions will be up forward enough to hoe; at which time (choosing dry weather) you should, with a small hoe about two inches and a half broad, cut up lightly all the weeds from amongst the Onions; and also cut out the Onions where they grow too close in bunches, leaving them at this first hoeing at least two inches apart. This, if well performed, and in a dry season, will preserve the ground clear of weeds at least a month or five weeks; when you must hoe them over a second time, cutting up all the weeds as before, and also cut out the Onions to a larger distance, leaving them this time three or four inches asunder. This also, if well performed, will preserve the ground clean a month or six weeks longer, when you must hoe them over the third and last time.

Now you must carefully cut up all weeds, and single out the Onions to near six inches square; by which means they will grow much larger, than if left too close. This time of hoeing, if the weather proves dry and it is well performed, will keep the ground clean until the Onions are fit to pull up; but if the weather should prove moist, and any of the weeds should take root again, you should, about a fortnight or three weeks after, go over the ground and draw out all the large weeds with your hands; for the Onions having now begun to bulb, they should not be disturbed with a hoe.

Toward the middle of August your Onions will have arrived to their full growth, which may be known by their blades falling to the ground and shrinking; you should therefore, before their necks or blades are withered off, draw them out of the ground, cropping off the extreme part of the blade, and lay them abroad upon a dry spot of ground to dry, observing to turn them over every other day at least, to prevent their

K k k

striking

striking fresh root into the ground; which they will suddenly do, especially in moist weather.

In about a fortnight's time your Onions will be dry enough to house, which must be performed in perfect dry weather; in doing of this, you must carefully rub off all the earth from the roots, and be sure to mix no faulty ones amongst them, which will in a short time decay, and spoil all those that lie near them; nor should you lay them too thick in the house, which would occasion their sweating, and thereby rot them; nor should they be put in a lower room, or ground floor, but in a loft or garret; and the closer they are kept from the air, the better they will keep. You should, at least, once a month, look over them to see if any of them are decayed; which if you find, must be immediately taken away, otherwise they will infect all that lie near them.

But notwithstanding all the care you can possibly take in the drying and housing of your Onions, many of them will grow in the loft, especially in mild winters, which are generally moist; therefore those who would preserve them late in the season, should select a parcel of the firmest and most likely to keep from the others, and with a hot iron slightly singe their beards, or roots, which will effectually prevent their sprouting; but in doing of this there must be great caution used not to scorch the pulp of the Onions, for that will cause them to perish soon after.

The best Onions for keeping are the Strasburgh kind, which is an oval-shaped bulb; but this seldom grows so large as the Spanish, which is flatter; the white sort is esteemed the sweetest; but these varieties are not lasting; for if you save seeds of white Onions only, you will have a mixture of the red ones amongst them; nor will the Strasburgh Onion keep long to its kind, but will by degrees grow flatter, as do the large Portugal Onions, when planted in our climate, which in a year or two will be so far degenerated, as not to be known they were from that race.

But in order to save seeds, you must in the spring make choice of some of the firmest, largest, and best shaped Onions (in quantity proportionable to the seed you intend to save;) and having prepared a piece of good ground (which should be well dug, and laid out in beds about three feet wide,) in the beginning or middle of March you must plant your Onions in the following manner. Having strained a line about four inches within the side of the bed, you must, with a spade, throw out an opening about six inches deep, the length of the bed, into which you should place the Onions, with their roots downward, at about nine inches distance from each other; then with a rake draw the earth into the opening again to cover the bulbs; then proceed to remove the line again about a foot farther back, where you must make an opening as before, and so again till the whole is finished; so that you will have four rows in each bed, between which you must allow a space of two feet for an alley to go among them to clear them from weeds, &c. In a month's time their leaves will appear above ground, and many of the roots will produce three or four stalks each; you must therefore keep them diligently cleared from weeds, and about the beginning of June, when the heads of the flowers begin to appear upon the tops of the stalks, you must provide a parcel of stakes about four feet long, which should be driven into the ground, in the rows of Onions, at about six or eight feet apart; to which you should fasten some packthread, rope yarn, or small cord, which should be run on each side the stems of the Onions, a little below their heads, to support them from breaking down with the wind and rain; for when the seeds are formed, the heads will be heavy, and so are very often broken down by their own weight, where they are not well secured; and if the stalks are broken before the seeds have arrived to maturity, they will not be near so good, nor keep so long as those which are perfectly ripened. About the end of August the Onion seed will be ripe, which may be known by its changing brown,

and the cells in which the seeds are contained opening; so that if it be not cut in a short time, the seeds will fall to the ground: when you cut off the heads, they should be spread abroad upon coarse cloths in the sun, observing to keep it under shelter in the night, as also in wet weather; and when the heads are quite dry, you must beat out the seeds, which are very easily discharged from their cells; then having cleared it from all the husk, &c. after having exposed it one day to the sun to dry, you must put it up in bags to preserve it for use.

The directions here given is for the general crop of winter Onions; but there are two other crops of this common sort of Onion, cultivated in the gardens about London to supply the market, one of which is commonly called Michaelmas Onions. These are sown in beds pretty close, the middle of August, and must be well weeded when they come up. In the spring of the year, after the winter Onions are over, they are tied up in bunches to supply the markets; but from the thinning of these they carry to market young green Onions in March, for sallads, &c.

And in the spring they sow more beds in the same manner, to draw up young for fallads, after the Michaelmas Onions are grown too large for that purpose; and where a supply of these are required, there may be three different sowings, at about three weeks distance from each other, which will be sufficient for the season.

There are also the following sorts of Onions cultivated in the kitchen-gardens.

The Shallot, or Eschalottes, which is the *Cepa Acalonica*. Matth. 556.

The Ciboule, or *Cepa fissilis*. Matth. Lugd. 1539.

The Cives, or *Cepa festilis juncifolia perennis*. Mor. Hist. 2. 383.

The Welch Onion I suppose to be the same with the Ciboule, although they pass under different appellations; for I have several times received the Ciboule from abroad, which, when planted, prove to be what is generally known here by the title of Welch Onions. There is also a great affinity between the Eschalottes and these, so that they are not well distinguished yet; for although they are generally cultivated in the gardens, yet they are not well known to the botanists, some of whom have supposed a greater variety than is in nature; while others have joined them together, making but two species.

The Scallion, or Escallion, is a sort of Onion which never forms any bulbs at the roots, and is chiefly used in the spring for green Onions, before the other sorts, sown in July, are big enough; but this sort of Onion, how much soever in use formerly, is now so scarce as to be known to few people, and is rarely to be met with, except in curious botanic gardens: the gardeners near London substitute another sort for this, which are those Onions which decay and sprout in the house: these they plant in a bed early in the spring, which in a short time will grow large enough for use; when they draw them up, and after pulling off all the outer coat of the root, they tie them up in bunches, and sell them in the market for Scallions.

The true Scallion is easily propagated by parting the roots, either in spring or autumn; but the latter season is preferable, because of their being rendered more fit for use in the spring: these roots should be planted three or four in a hole, at about six inches distance every way, in beds or borders three feet wide, which in a short time will multiply exceedingly, and will grow upon almost any soil and in any situation; and their being so hardy as to resist the severest of our winters, and being green, and fit for use so early in the spring, renders them worthy of a place in all good kitchen-gardens.

The Cives are a very small sort of Onion, which never produce any bulbs, and seldom grow above six inches high in the blade, which is also very small and slender, and are in round bunches like the former;
this

C E P

this was formerly in great request for fallads in the spring, as being milder than those Onions which had stood through the winter; these are propagated by parting their roots like the former, and are also very hardy, and will be fit for use early in the spring.

The Welch Onions are only propagated for spring use also; these never make any bulb, and are therefore only fit to be used green for fallads, &c. They are sown about the end of July, in beds of about three feet and a half wide, leaving alleys of two feet broad to go between the beds to clean them, and in a fortnight's time they will appear above ground, when they must be carefully cleared from weeds; towards the middle of October their blades will die away, so that the whole spot will seem to be naked, which hath led many people to dig up the ground again, supposing the crop totally lost; whereas, if they stand undisturbed, they will come up again very strong in January, and from that time grow very vigorously, resisting all weathers; and by March will be fit to draw for young Onions, and are, in the markets, more valued than any other sort at that season; for they are extremely green and fine, though they are much stronger than the common Onion in taste, approaching nearer to Garlick, which hath occasioned their being less esteemed for the table: but as no winter, however hard, will hurt them, it is proper to have a few of them to supply the table, in case the common sort should be destroyed by frosts.

The roots of these Onions, if planted out at six or eight inches distance, in March, will produce ripe seeds in autumn, but it will be in small quantities the first year; therefore the same roots should remain unremoved, which the second and third year will produce many stems, and afford a good supply of seeds; these roots will abide many years good, but should be transplanted and parted every second or third year, which will cause them to produce strong seeds.

C E P H A L A N T H U S. Lin. Gen. Plant. 105. *Platanocephalus*. Vaill. Acad. R. Scien. 1722. Button Wood.

The CHARACTERS are,

It hath a number of small flowers, which are collected into a spherical head; these have no common empalement, but each particular flower hath a funnel-shaped empalement, divided into four parts at the top; the flower is funnel-shaped, of one petal, divided at the top into four parts, inclosing four stamina, which are inserted in the petal, and are shorter than the tube, being terminated by globular summits. The germen is situated under the flower, supporting a style which is longer than the petal, and is crowned by a globular stigma; the germen afterward becomes a globular hairy capsule, inclosing one or two oblong angular seeds; these are joined to an axis, and form a round head.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and but one style.

We have but one SPECIES of this plant, viz.

C E P H A L A N T H U S (*Occidentalis*) foliis oppositis ternisque. Flor. Virg. 15. *Button-tree with leaves growing opposite, and sometimes by threes. Scabiosa dendroides Americana* ternis foliis caulem ambientibus, floribus ochroleucis. Pluk. Alm. 336. tab. 77.

This shrub grows naturally in North America, from whence the seeds are annually sent to Europe, and of late years great numbers of the plants have been raised in the gardens of the curious; but there are no very large plants in the English gardens; the largest I have seen are in the curious gardens of his grace the Duke of Argyle, at Whitton, near Hounslow, where they thrive better than in almost any other place where they have been planted, so that in a moist soil they will do the best.

This seldom rises higher than six or seven feet in this country. The branches come out by pairs, opposite at each joint; the leaves also stand opposite, sometimes by pairs, and at other times there are three

C E R

arising at the same joint, standing round the branch; these are near three inches long, and one and a quarter broad, having a strong vein running longitudinally through the middle, and some small transverse veins from that to the borders; they are of a light green, and their foot-stalks change to a reddish colour next the branches; the ends of the branches are terminated by loose spikes of spherical heads, about the size of a marble, each of which are composed of many small flowers, which are funnel-shaped, of a whitish yellow colour, fastened to an axis which stands in the middle; these appear in July, and, in warm seasons, are succeeded by seeds, which have sometimes ripened in England.

These plants are propagated chiefly by seeds (though there has been some raised from cuttings and layers;) these should be sown in pots, for the greater convenience of removing them either into a shady situation, or where they may have shelter. If the seeds can be procured so early as to sow them before Christmas, the plants will come up the following summer; but if they are sown in the spring, they generally remain a year in the ground; therefore, in such case, the pots should be placed in the shade that summer, and in the autumn following removed under a common frame to shelter them from frost, and the spring following the plants will come up.

The first year, when the plants come up, it will be necessary to shade them in hot dry weather, while they are young, at which time they are often destroyed by being too much exposed; nor should the watering be neglected; for as these plants naturally grow on moist ground, so when they are not duly watered in dry weather, the young plants will languish and decay.

The next autumn, when the leaves begin to drop, the young plants may be transplanted into nursery-beds, which should be a little defended from the cold winds; and, if the soil is moist, they will succeed much better than in dry ground; but where it happens otherwise, it will be absolutely necessary to water them in dry weather, otherwise there will be great danger of the plants dying in the middle of summer, which has been the case in many gardens where these plants were raised.

In these nursery-beds the plants may remain a year or two (according to the progress they may have made, or the distance they were planted;) then they may be taken up in October, and transplanted where they are to remain for good. Although I have mentioned but one season for transplanting them, yet this may also be performed in the spring, especially if the ground is moist into which they are removed, or that the plants are duly watered, if the spring should prove dry, otherwise there will be more hazard of their growing when removed at this season.

These plants make a pretty variety among other hardy trees and shrubs, being extreme hardy in respect to cold; but they delight in a moist light soil, where they will grow very fast, and their leaves will be larger than in dry land.

C E R A S T I U M. Lin. Gen. Plant. 518. Mouse-ear, or Mouse-ear Chickweed; in French, *Oreille de Souris*.

The CHARACTERS are,

It hath a permanent five-leaved empalement, which spreads open; the flower hath five obtuse bifid petals, which are as large as the empalement. It hath ten slender stamina shorter than the petals, terminated by roundish summits. In the center is situated an oval germen, from which arise five styles, which are hairy, erect, and crowned with obtuse stigma; the empalement afterward becomes an oval, cylindrical, or globular capsule with one cell, opening at the top, containing many roundish seeds.

This genus of plants is ranged in the fourth section of Linnæus's tenth class, intitled Decandria Pentagynia, the flower having ten stamina and five styles.

C E R

The SPECIES are,

1. CERASTIUM (*Repens*) foliis lancolatis, pedunculis ramosis, capsulis subrotundis. Lin. Sp. Plant. 439. *Cerastium with spear-shaped leaves, branching foot-stalks, and roundish capsules.* Myosotis incana repens. Tourn. Inst. R. H. 245. *Hoary creeping Mouse-ear, by some called Sea Pink.*
2. CERASTIUM (*Tomentosum*) foliis oblongis, tomentosis, pedunculis ramosis, capsulis globosis. Lin. Sp. Plant. 440. *Cerastium with oblong woolly leaves, branching foot-stalks, and globular capsules.* Myosotis tomentosa, linariae folio angustiore. Tourn. Inst. R. H. 245. *Woolly Mouse-ear with a narrow Toad-flax leaf.*
3. CERASTIUM (*Dichotomum*) foliis lanceolatis, caule dichotomo ramosissimo, capsulis erectis. Prod. Leyd. 450. *Cerastium with spear-shaped leaves, a very branching stalk divided in forks, and upright capsules.* Myosotis Hispanica segetum. Tourn. Inst. R. H. 545. *Spanish Corn Mouse-ear, or Horned Chickweed.*
4. CERASTIUM (*Pentandrum*) floribus pentandriis, petalis integris. Lin. Sp. Plant. 438. *Cerastium with flowers having five stamina, and entire petals.*
5. CERASTIUM (*Perfoliatum*) foliis connatis. Hort. Cliff. 173. *Cerastium whose leaves are joined.* Myosotis Orientalis perfoliata folio lychnidis. Tourn. Cor. 18. *Eastern perfoliated Mouse-ear with a Lychnis leaf.*

The first sort grows naturally in France and Italy, and was formerly cultivated in the English gardens under the title of Sea Pink; one of the uses made of it was to plant it as an edging to keep up the earth of borders; but this was before the Dwarf Box was brought to England, since which all those plants which were formerly applied for this purpose have been neglected. This plant was by no means fit for this use, because its creeping branches would spread into the walks where they put out roots into the gravel; so that unless they are frequently cut off, they cannot be kept within compass.

This sends out many weak stalks which trail upon the ground, and put out roots at their joints, whereby it propagates very fast; the leaves are placed by pairs opposite, which are about two inches long, and little more than half an inch broad, very hoary; those next the root are much smaller than the upper; the flowers come out from the side of the stalks upon slender foot-stalks, which branch out into several smaller, each supporting a white flower, composed of five petals, which are split at the top. The whole flower has the appearance of Chickweed flowers, but are larger; it flowers in May.

It propagates too fast by its creeping roots and trailing branches, when it is admitted into gardens, so may be planted in any soil or situation; and is very proper to be planted between stones on the side of grottos, where it will spread, and thrive without care.

The seeds of the second sort I received from Istria, where it naturally grows; this is by Parkinson titled hoary narrow-leaved Pink. The leaves of this sort are narrower than those of the former, and are much whiter; the stalks grow more erect, and the seed-vessels are rounder, in which their chief difference consists. This is a trailing plant, and propagates by sending out roots at the joints, in the same manner as the former, and is equally hardy. It flowers in May and June, and the seeds ripen in August.

The third sort is annual; this grows naturally on arable land in Spain, from whence the seeds were sent to England, where it is allowed a place in botanic gardens for the sake of variety, but hath not much beauty; this hath branching stalks, which grow about six inches high, dividing by pairs in forks, the flowers coming out in the middle of the divisions, which are shaped like those of Chickweed; the whole plant has a clammy moisture, which sticks to the fingers of those who handle it. This flowers in May, and the seeds ripen in July. If the seeds are sown in autumn, they will succeed better than in the spring; or if they are permitted to fall, the plants will rise without care.

C E R

The fourth sort is very like the third in its whole appearance, and differs from it, in having but five stamina in the flower, whereas the other hath ten. This was discovered by Mr. Læssing, a pupil of Dr. Linnæus's, in Spain, from whence he sent the seeds to Upsal, part of which were sent me by the Doctor.

The fifth sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris, where they succeeded, and have been since communicated to most of the curious botanic gardens in Europe. This is an annual plant, which rises with an upright stalk a foot high; the lower leaves of this plant have much resemblance to those of the Lychnis, which is called Lobel's Catchfly, so that when the plants are young, it is not easy to distinguish them. The stalks are garnished with leaves of the same shape, but smaller, placed by pairs, and embrace the stalks at their base. The flowers come out at the top of the stalks, and also from the wings of the leaves, on the upper part of the stalks, which are white, and shaped like those of Chickweed. They appear in May and June, and are succeeded by beaked capsules, containing many roundish seeds.

If the seeds of this sort are sown in autumn, they will more certainly grow than those which are sown in the spring; or if the seeds are permitted to scatter, the plants will come up and live through the winter, and will require no other care but to keep them clean from weeds.

There are many other species of this genus than are here enumerated, which are weeds in many parts of England, so are never cultivated in gardens, therefore not worthy of notice here.

CERASUS [*κέραυος*, Gr. so called according to Servius, from Cerasus, a city of Pontus, which Lucullus having destroyed, he carried the Cherry-tree from thence to Rome, and called it Cerasus, after the name of the city; but others will have it that the city took its name from the abundance of those trees which grew there.] The Cherry-tree.

The botanical characters of this genus, according to the system of Linnæus, are the same with those of Prunus; therefore he has joined the Apricot Cherry, Laurel, and Bird Cherry together, making them only species of the same genus; but those who admit of the fruit, as a character to determine the genus, must separate the Cherry from the others, because they differ greatly in the shape of their stones; but there is a more essential difference in nature between them, which is, that the Cherry will not grow upon a Plumb-stock, by budding or grafting, nor will the Plumb take upon a Cherry-stock; and yet we know of no trees of the same genus which do not unite with each other, by budding or grafting.

However, as the joining so many genera into one, would occasion great confusion among gardeners, who cultivate these trees for sale, therefore if there were no other motive than that, it would be a sufficient excuse for not closely following that system in this work, which is designed for the instruction of those who have not made botany their study; so I shall refer the reader to the article PRUNUS, under which the botanical characters will be inserted, and proceed to the species.

I shall first enumerate the sorts which are specifically different from each other, and then mention the varieties of these fruits, which are cultivated in the English gardens; many of which seem to differ so essentially from each other, that they may be allowed as specific differences; but as I have not had an opportunity of trying the various sorts from seeds, to see if they alter, so I chose to insert them only as varieties, till further observation may better settle their boundaries.

The SPECIES are,

1. CERASUS (*Vulgaris*) foliis ovato-lanceolatis, serratis. *The common, or Kentish Cherry.* Cerasus sativa rotunda rubra & acida. C. B. P. 449. *Manured Cherry with round, red, acid fruit.*

2. CERASUS (*Nigra*) foliis ferratis lanceolatis. *Cherry-tree with spear-shaped sawed leaves.* Cerasus major ac sylvestris, fructu subdulci nigro colore inficiente. C. B. P. 450. *Greater wild Cherry-tree with a sweetish fruit, whose juice affords a black colour.*
3. CERASUS (*Hortensis*) foliis ovato-lanceolatis, floribus confertis. *Cherry-tree with oval spear-shaped leaves, and flowers growing in clusters.* Cerasus racemosa hortensis. C. B. P. 450. *Commonly called the Cluster Cherry.*
4. CERASUS (*Mahaleb*) floribus corymbosis, foliis ovatis. Lin. Sp. Plant. 474. *Cherry-tree with flowers growing in round bunches, and oval leaves.* Cerasus sylvestris amara, mahaleb putata. J. B. *The Mahaleb or perfumed Cherry.*
5. CERASUS (*Canadensis*) foliis lanceolatis, glabris, integerrimis, subtus, caësiis, ramis patulis. *Cherry-tree with smooth, spear-shaped, entire leaves, of a bluish green on their under side, and spreading branches.* Cerasus pumila Canadensis, oblongo angusto folio fructu parvo. Du Hamel. *Dwarf Canada Cherry, with oblong narrow leaves, and a small fruit, called Ragouminier, Nega, or Minel in Canada.*

The first sort is the common or Kentish Cherry, which is so well known in England as to need no description. From this sort it hath been supposed many of the varieties which are cultivated in the English gardens, have been raised; but as there are very great differences in the size and shape of their leaves, as also in the shoots of the trees from those of this sort, I think it is very doubtful, where the boundaries of their specific differences terminate: however, I shall comply with the generality of modern botanists, in supposing the following sorts to have been produced from the seeds of this, as we have not sufficient experiments to determine otherwise.

The Early May Cherry.	The Ox Heart.
The May Duke Cherry.	The Lukeward.
The Archduke Cherry.	The Carnation.
The Flemish Cherry.	The Hertfordshire Heart.
The Red Heart.	The Morello.
The White Heart.	The Bleeding Heart.
The Black Heart.	Yellow Spanish Cherry.
The Amber Heart.	

Two sorts with double flowers, one larger and fuller than the other. These are propagated for ornament.

The second sort above-mentioned is the Black Cherry, which is supposed to be a native of England. This grows to be a large tree, fit for timber, and is frequently found growing as such in the woods. From this, the only varieties which I have ever known raised by seeds, are the Black Coroun, and the small Wild Cherry; of which there are two or three varieties, which differ in the size and colour of their fruit.

These Wild Cherries are very proper to plant in parks, because they grow to a large size, and make beautiful trees; and in the spring, when they are in flower, will be very ornamental. The fruit of them will be good food for birds, and when the trees are cut down, the wood is very useful for turners. These trees will thrive in poor land better than most other sorts, so there is an advantage in propagating them in those places. The French often plant them for avenues to their houses, upon such land where they cannot get any other trees to thrive; they also cultivate them in their woods to cut for hoops, and greatly esteem them for this purpose.

The stones of this sort are generally sown for raising stocks to graft or bud the other sorts of Cherries upon, being of quicker growth, and of longer duration than either of the other, so are very justly esteemed and preferred to them.

The wood of the fourth sort, is by the French greatly esteemed for making of cabinets, because it hath an agreeable odour. This, and the wood of the Bird Cherry, are often blended together, and pass under the appellation of Bois de Sainte Lucie; but the Bird Cherry is the true sort.

The fifth sort was brought from Canada, where it grows naturally, to the gardens in France, where it

is cultivated as a flowering shrub for ornament. The stones of this were sent me by Dr. Bernard de Jussieu, professor of botany at Paris, which succeeded very well in the Chelsea garden; but by comparing this with a specimen of the old Chamæcerasus, or Cerasus humilis of Gerard, and other old writers, I find it to be the same plant, for it also agrees exactly with their descriptions of it.

This is a low shrub, which seldom grows more than three or four feet high, sending out many horizontal branches, which spread near the ground on every side; and the lower branches are very subject to lie in the ground, where they will put out roots, and thereby multiply. The young branches have a very smooth bark, inclining toward red; the leaves are long, narrow, very smooth, and entire, having the appearance of some sorts of Willow leaves, of a light green on their upper side, but of a bluish or sea-green on their under: the flowers come out from the side of the branches, two, three, or four arising at the same joint most part of the length of the young shoots; these are shaped like those of the common Cherry, but are smaller, standing upon long slender foot-stalks. The fruit is like those of the small wild Cherry, but hath a bitterish flavour. It flowers about the same time as the other sorts of Cherries, and the fruit ripens in July; these fruit are good food for birds, and the French plant them among their other shrubs, to entice the birds to harbour there.

It is easily propagated by laying down the branches early in the spring, which will take root by the following autumn, when they may be taken off, and either planted in a nursery to get strength, or to the places where they are designed to remain. It may also be propagated by sowing the stones, in the same manner as other Cherries.

All the sorts of Cherries which are usually cultivated in fruit-gardens, are propagated by budding or grafting the several kinds into stocks of the Black or wild Red Cherries, which are strong shooters, and of longer duration than any of the garden kinds. The stones of these two kinds are sown in a bed of light sandy earth in autumn (or are preserved in sand till spring, and then sowed.) When these stocks arise they must be carefully weeded, and if in dry weather you refresh them with water, it will greatly promote their growth. These stocks should remain in the nursery-beds till the second autumn after sowing; at which time you should prepare an open spot of good fresh earth, which should be well worked; but if the soil is fresh, it will be the better. In this ground, in October, you should plant out the young stocks at three feet distance row from row, and about a foot asunder in the rows, being careful in taking them up from their seed-beds to loosen their roots well with a spade, to prevent their breaking, as also to prune their roots; and if they are inclinable to root downwards, you should shorten the tap-root to cause it to put out lateral roots; but do not prune their tops, for this is what by no means they will endure.

The second year after planting out, if they take to growing well, they will be fit to bud, if they are intended for dwarfs: but if they are for standards, they will not be tall enough until the fourth year; for they should be budded or grafted near six feet from the ground, otherwise the graft will not advance much in height; so that it will be impossible to make a good tree from such as are grafted low, unless the graft is trained upward.

The usual way with the nursery gardeners is to bud their stocks in summer, and such of them as miscarry they graft the succeeding spring (the manner of these operations will be described under their proper heads.) Those trees where the buds have taken, must be headed off in the beginning of March about six inches above the bud; and when the bud hath shot in summer, if you fear its being blown out by the winds, you may fasten it up with some bafs, or any other soft binding, to that part of the stock which was left above

the bud. The autumn following these trees will be fit to remove; but if your ground is not ready to receive them, they may remain two years before they are transplanted; in doing which, you must observe not to head them, as is by many practised, for this very often is immediate death to them; but if they survive it, they seldom recover this amputation in five or six years.

If these trees are intended for a wall, I would advise the planting dwarfs between the standards; so that while the dwarfs are filling the bottom of the walls; the standards will cover the tops, and will produce a great deal of fruit: but these, as the dwarfs arise to fill the walls, must be cut away to make room for them; and when the dwarf trees cover the walls, the standards should be entirely taken away. But I would advise, never to plant standard Cherries over other fruits, for there is no other sort of fruit that will prosper well under the drip of Cherries.

When these trees are taken up from the nursery, their roots must be shortened, and all the bruised parts cut off; and also all the small fibres, which would dry, grow mouldy, and be a great prejudice to the new fibres in their coming forth; you must also cut off the dead part of the stock which was left above the bud, close down to the back part of it, that the stock may be covered by the bud. If these trees are designed for a wall, observe to place the bud directly from the wall, that the back part of the stock that was cut may be hid from sight. The soil that Cherries thrive best in, is a fresh hazel loam; but if the soil is a dry gravel, they will not live many years, and will be perpetually blighted in the spring.

The sorts commonly planted against walls, are the Early May, and May Duke, which should have a south aspect wall. The Hearts and common Duke will thrive on a west wall; and in order to continue this sort later in the season, they are frequently planted against north and north-west aspect walls, where they succeed very well; and the Morello on a north wall, which last is chiefly planted for preserving. The Hearts are all of them ill bearers, for which reason they are seldom planted against walls: but I am apt to believe, if they were grafted upon the Bird Cherry, and managed properly, that defect might be remedied; for this stock (as I am informed) will render Cherries very fruitful; and having the same effect on Cherries, as the Paradise stock hath on Apples, they may be kept in less compass, which is an experiment well worth the trial.

Your trees, if planted against a wall, should be placed at least twenty or twenty-four feet asunder, with a standard tree between each dwarf: this will be found a reasonable distance, when we consider, that Cherry-trees will extend themselves full as far as Apricots, and many other sorts of fruit.

In pruning these sorts of fruit, you should never shorten their shoots; for the most part of them produce their fruit buds at the extremities, which, when shortened, are cut off, and this often occasions the death of the shoot, at least a good part of its length: their branches should be therefore trained in at full length horizontally, observing in May, where there is a vacancy in the wall, to stop some strong adjoining branches, which will occasion their putting out two or more shoots; by which means, at that season of the year, you may always get a supply of wood for covering the wall; and at the same time, should all foreright shoots be displaced by the hand; for if they are suffered to grow till winter, they will not only deprive the bearing branches of their proper supply of nourishment, but when they are cut out, it occasions the tree to gum in that part (for Cherries bear the knife the worst of any sort of fruit trees;) but be careful not to rub off the sides or spurs, which are produced upon the two and three years old wood; for it is upon these that the greatest part of the fruit are produced, which sides will continue fruitful for several years. And it is for want of duly observing this caution, that Cherry-trees are often seen so unfruitful, especially the Morello, which the more

it is cut the weaker it shoots; and, at last, by frequent pruning, I have known a whole wall of them destroyed; which, if they had been suffered to grow without any pruning, might probably have lived many years, and produced large quantities of fruit.

Cherry-trees are also planted for orchards in many parts of England, particularly in Kent, where there are large plantations of these trees. The usual distance allowed for their standing is forty feet square, at which space they are less subject to blight than when they are closer planted; and the ground may be tilled between them almost as well as if it were entirely clear, especially while the trees are young; and often stirring the ground, provided you do not disturb their roots, will greatly help the trees; but when they are grown so big as to over-shadow the ground, the drip of their leaves will suffer very few things to thrive under them. These standard trees should be planted in a situation defended as much as possible from the strong westerly winds, which are very apt to break their tender branches; this occasions their gumming, and is very prejudicial to them. The sorts best approved for an orchard, are the common Red, or Kentish Cherry, the Duke, and Luke-ward; all which are plentiful bearers. But orchards of these trees are now scarcely worth planting, except where land is very cheap; for the uncertainty of their bearing, with the trouble in gathering the fruit, together with the small price it commonly yields, hath occasioned the destroying many orchards of this fruit in Kent within a few years past.

This fruit was brought out of Pontus, at the time of the Mithridatic victory, by Lucullus, in the year of the city 680, and were brought into Britain about 120 years afterward, which was An. Dom. 55; and were soon after spread through most parts of Europe, it being generally esteemed for its earliness, as being one of the first of the tree fruit that appears to welcome in the approaching fruit season.

This sort of fruit hath been by many people grafted upon the Laurel, to which it is a congener; but the effect it hath in the growth of the tree, as also in its fruit, will not recommend it to practice, the trees being of short duration, and seldom produce much fruit; though this practice is as old as Pliny, who says it gives the fruit a pleasant bitterness: but there is little to be depended upon in the writings of the ancients, with respect to the several sorts of trees being grafted upon each other; very few of those which we find mentioned by them to have been frequently practised, will not succeed with us. Nor is it owing to the difference of climate, as some have supposed, who are inclinable to believe whatever they find related in those books, especially in the business of husbandry and gardening; whereas many of the rules for the practical part of husbandry, are not founded on experiments, but are mere theory; for from many repeated trials which have been made with the utmost care, by persons of the best skill, it appears, that no two sorts of trees, which are of different classes, will take upon each other. However, the Laurel and the Cherry being of the same genus, or so near of kin to be ranked together by most botanists, will take upon each other by grafting. But I have not yet seen any of the trees so grafted, which have lived to be of any considerable size; though I have seen many trees so grafted, which have lived a few years, but have made very poor progress; nor do I remember to have seen any fruit upon the Cherry-trees which were grafted on the Laurels, therefore cannot determine what effect this has on the flavour of the fruit.

There are some persons who graft the Duke, and other sorts of Cherries, upon the Morello Cherry, which is but a weak shooter, in order to check the luxuriant growth of their trees, which will succeed for three or four years: but they are not of long duration, nor have I ever seen one tree so grafted, which had made shoots above six or eight inches long, but they were closely covered with blossoms, so may produce

C E R

duce some fruit in a small compass; but these are experiments unfit to be carried into general use, and only proper to satisfy curiosity; for is it not much better to allow the trees a greater share of room against the walls, when one tree so planted and properly managed, will produce more fruit than twenty of these trees, or twice that number, when they are planted too close, though they are grafted upon the Black Cherry or any other free stock.

The Early or May Cherry is the first ripe, so one or two trees of this sort may be allowed a place in a garden, where there is room for variety. The next ripe is the May Duke, which is a larger fruit than the other, and is more valuable. After this comes the Archduke, which, if permitted to hang upon the tree till the fruit is quite ripe, is an excellent Cherry; but few persons have patience to let them hang their full time, so rarely have them in perfection, for these should not be gathered before July; and if they hang a fortnight longer they will be better. This is to be understood of the situation near London, where they ripen a fortnight earlier than in places forty miles distant, unless they have a very warm sheltered situation. When this sort is planted against north walls, the fruit may be continued till the middle of August; but these must be protected from the birds, otherwise they will destroy them.

The Hertfordshire Cherry, which is a sort of Heart Cherry, but a firmer and better flavoured fruit, will not ripen earlier than the end of July, or the beginning of August, which makes it the more valuable for its coming when the other sorts of Cherries are gone. This is now pretty common in the nurseries; but as it is one of the best kind of Cherries, it is well worthy of being propagated in the nurseries.

The Morello Cherry, which is generally planted against walls to a north aspect, and the fruit commonly used for preserving; yet where they are planted to a better aspect, and suffered to hang upon the trees until they are thoroughly ripe, is a very good fruit for the table; therefore some of the trees of this sort should have place where there is plenty of walling, upon a south-west wall, where they will ripen perfectly by the middle or end of August, at which time they will be an acceptable fruit.

The Carnation Cherry is also valuable for coming late in the season; this has a very firm fleshy fruit, but is not the best bearer. This sort will some seasons ripen very well on espaliers, and by this means the fruit may be continued longer in the season.

The large Spanish Cherry is nearly allied to the Duke Cherry, from which it seems to be only a variety accidentally obtained; this ripens soon after the common Duke Cherry, and very often passes for it.

The yellow Spanish Cherry is of an oval shape and of an amber colour; this ripens late, and is a sweet Cherry, but not of a rich flavour; and being but a middling bearer, is not often admitted into curious gardens, unless where variety is chiefly considered.

The Corone, or Coroun Cherry, is somewhat like the Black Heart, but a little rounder; this is a very good bearer and an excellent fruit, so should have a place in every good fruit-garden. This ripens the middle of July.

The Lukeward ripens soon after the Corone Cherry; this is a good bearer, and a very good fruit; it is of a dark colour, not so black as the Corone; this will do well in standards.

The Black Cherry is seldom grafted or budded, but is generally sown for stocks to graft the other kinds of Cherries upon; but where persons are curious to have the best flavoured of this sort of fruit, they should be propagated by grafting from such trees as produce the best fruit. This sort of Cherry is frequently planted in wildernesses, where it will grow to a large size, and, at the time of its flowering, will make a variety, and the fruit will be food for the birds.

The double-flowering Cherry is also propagated for the beauty of the flowers, which are extremely fine,

C E R

the flowers being as double and large as a Cinnamon Rose; and these being produced in large bunches on every part of the tree, render it one of the most beautiful trees of the spring. Some of the flowers which are less double, will often produce some fruit, which the very double flowers will not; but this defect is sufficiently recompensed in the beauty of its flowers. This is propagated by budding or grafting on the Black or Wild Cherry stock, and the trees are very proper to intermix with the second growth of flowering trees.

CERASUS RACEMOSA. See PADUS.

CERATONIA. Lin. Gen. Plant. 983. Siliqua. Tourn. Inst. R. H. 578. tab. 344. The Carob, or St. John's Bread, in French *Carouge*.

The CHARACTERS are,

It is male and female in distinct trees. The male flowers have large empalements, divided into five parts; they have no petals, but have five long stamina, terminated by large summits. The female flowers have empalements of one leaf, divided by five tubercles; they have no petals, but a fleshy germen situated within the receptacle, supporting a slender style, crowned by a stigma in form of a head. The germen afterward becomes a long, fleshy, compressed pod, divided by transverse partitions, each having one large, roundish, compressed seed.

This genus of plants is ranged in the third section of Linnæus's twenty-third class, intitled Polygamia Triœcia. The plants of this class have male, female, and hermaphrodite flowers on distinct plants.

We have but one SPECIES of this genus, viz.

CERATONIA (*Siliqua*.) H. L. The Carob-tree, or St. John's Bread. *Siliqua edulis* of Caspar Bauhin, and the Caroba of Dale.

This tree is very common in Spain, and in some parts of Italy, as also in the Levant, where it grows in the hedges, and produces a great quantity of long, flat, brown-coloured pods, which are thick, mealy, and of a sweetish taste. These pods are many times eaten by the poorer sort of inhabitants when they have a scarcity of other food, but they are apt to loosen the belly, and cause gripings of the bowels. The pods are directed by the College of Physicians to enter some medicinal preparations, for which purpose they are often brought from abroad.

In England the tree is preserved by such as delight in exotic plants, as a curiosity; the leaves always continue green, and being different in shape from most other plants, afford an agreeable variety when intermixed with Oranges, Myrtles, &c. in the greenhouse.

These plants are propagated from seeds, which, when brought over fresh in the pods, will grow very well, if they are sown in the spring upon a moderate hot-bed; and when the plants are come up they should be carefully transplanted each into a separate small pot filled with light rich earth, and plunged into another moderate hot-bed, observing to water and shade them until they have taken root; after which you must let them have air, in proportion to the heat of the weather. In June you must inure them to the open air by degrees; and in July they should be removed out of the hot-bed, and placed in a warm situation, where they may remain until the beginning of October, when they should be removed into the greenhouse, placing them where they may have free air in mild weather; for they are pretty hardy, and require only to be sheltered from hard frosts. When the plants have remained in the pots three or four years, and have gotten strength, some of them may be turned out of the pots in the spring, and planted into the full ground, in a warm situation, near a south wall, where they will endure the cold of our ordinary winters very well, but must have some shelter in very hard weather.

I have not as yet seen any of these trees produce flowers, though from some which have been planted some time against walls, it is probable there may be flowers and fruit in a few years; though it cannot be expected that the fruit will ever ripen in this country.

C E R.

CERBERA. Lin. Gen. Plant. 260. Thevetia. Lin. Hort. Cliff. 76. Prod. Leyd. 413. Ahouai. Tourn. Inst. R. H. 657. tab. 434.

The CHARACTERS are,

The empalement is composed of five sharp-pointed leaves, which spread open and fall away. The flower is of one leaf, funnel-shaped, having a long tube spread open at the top, where it is divided into five large obtuse segments, standing oblique to the mouth of the tube; it hath five stamina situated in the middle of the tube, which are terminated by erect summits; these stand close together. In the center is situated a roundish germen, supporting a short style, crowned by a stigma in form of a head. The germen afterward becomes a large, fleshy, roundish berry, with a longitudinal furrow on the side, dividing it into two cells, each containing a single, large, compressed nut.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CERBERA (*Ahouai*) foliis ovatis. Lin. Sp. Plant. 208. *Cerbera with oval leaves.* Ahouai. Thevet. Antarct. 66. Tourn. Inst. 658. *The Ahouai.*
2. CERBERA (*Thevetia*) foliis linearibus, longissimis, confertis. Lin. Sp. Plant. 209. *Cerbera with very long narrow leaves growing in clusters.* Ahouai Nerii folio, flore luteo. Plum. Cat. 20. *Ahouai with a Rose-bay leaf, and a yellow flower.*
3. CERBERA (*Manghas*) foliis lanceolatis, nervis transversalibus. Flor. Zeyl. 106. *Cerbera with spear-shaped leaves and transverse nerves.* Manghas lactescens, foliis Nerii crassis venosis, Jasmini flore, fructu Persici simili venenato. Burm. Zeyl. 150. tab. 70.

The first sort grows naturally in the Brazils, and also in the Spanish West Indies in plenty; and there are some of the trees growing in the British islands of America; this rises with an irregular stem to the height of eight or ten feet, sending out many crooked diffused branches, which toward their tops are garnished with thick succulent leaves about three inches long, and near two broad, of a lucid green, smooth, and very full of a milky juice, as is every part of the shrubs. The flowers come out in loose bunches at the end of the branches, of a cream colour, having long narrow tubes at the top cut into five obtuse segments, which seem twisted, so as to stand oblique to the tube; these spread open, and have the appearance of the flowers of Oleander. It flowers in July and August, but never produces fruit in England. The wood of this tree stinks most abominably, and the kernels of the nuts are a most deadly poison; so that the Indians always caution their children against eating them, for they know of no antidote to expel this poison; nor will any of them use the wood of this tree for fuel, but they take the kernels out of the shells, into which they put small stones, then bore a hole through each shell, and string them; these they tie about their legs to dance with, as the morris-dancers use bells.

The second sort grows naturally in the Spanish West Indies, and also in some of the French islands in America, and hath lately been introduced into the British islands, from whence I received the seeds by the title of French Physic Nut; but how it came by that appellation, I cannot imagine, because there is another plant which grows common there, and has passed under that title many years.

This rises with a round stalk about the same height as the former, dividing upward into many branches. These, when young, are covered with a green smooth bark, but as they grow older, the bark becomes rough, but changes to a gray or Ash-colour. The leaves are four or five inches long, and half an inch broad in the middle, ending in sharp points, of a lucid green, and come out in clusters without order, and are full of a milky juice, which flows out when they are broken. The flowers come out from the side of the branches upon long foot-stalks, each supporting two or three yellow flowers with long tubes, spreading open in the same manner as the former. It flowers

about the same time as the former, but never produces fruit in England.

The third sort grows naturally in India, and also in some parts of the Spanish West Indies, from whence I received the seeds; this rises with a woody stem to the height of twenty feet, sending out many branches toward the top, garnished with long spear-shaped leaves, which are rounded at their ends; they are thick, succulent, and, on their upper side, of a lucid green, having several transverse nerves from the midrib to the side; on their under side they are of a paler green. The flowers are produced at the end of the branches, standing on long foot-stalks, each sustaining two or three flowers shaped like those of the other species.

These plants may be propagated from their nuts, which must be procured from the countries where they grow naturally; these should be put into small pots filled with light earth, and plunged into a hot-bed of tanners bark in the spring, and treated in the same manner as other tender exotic seeds, giving them now and then a little water to promote their vegetation. When the plants are come up about two inches high, they should be transplanted each into a separate pot, filled with light sandy earth, and plunged again into a hot-bed of tanners bark, observing to shade the glasses in the heat of the day, until the plants have taken new root; they must also be frequently refreshed with water, but it must not be given in too large quantities. As the summer advances, these plants should have air admitted to them in proportion to the warmth of the season; and when they have filled these small pots with their roots, they should be turned out and transplanted into other pots of a larger size, but they must not be too large; for the roots of these plants should be confined, nor should the earth in which they are planted be rich, but a light sandy soil is best for them; after they are new potted they should be plunged into the hot-bed again, observing to water them now and then, as also to admit air under the glasses every day in proportion to the warmth of the season. When the plants are grown about a foot high, they should have a larger share of air, in order to harden them before the winter, but they should not be wholly exposed to the open air. In the winter these plants should be placed in a warm stove, and during that season they should have very little water given to them, especially in cold weather, lest it should rot their roots. In the following spring these plants should be shifted again into other pots, at which time you should take away as much as you conveniently can of the old earth from their roots, and afterwards cut off the decayed fibres; then put them into pots filled with the same light sandy earth, and plunge them into the bark-bed again, for these plants will not thrive well unless they are constantly kept in tan: and as they abound with milky juice, they should be sparingly watered, for they are impatient of moisture, especially during the winter season.

When by any accident the tops of these plants are injured, they frequently put out shoots from their roots, which, if carefully taken up and potted, will make good plants, so that they may be this way propagated.

CERCIS. Lin. Gen. Plant. 458. Siliquastrum. Tourn. Inst. R. H. 646. tab. 414. The Judas-tree, in French *Guainier*.

The CHARACTERS are,

It hath a short bell-shaped empalement of one leaf, which is convex at the bottom, and full of honey liquor; at the top it is indented in five parts. The flower hath five petals, which are inserted in the empalement, and greatly resembles a papilionaceous flower. The two wings rise above the standard, and are reflexed; the standard is of one roundish petal, and the keel is composed of two petals, in form of a heart, which inclose the parts of generation. It hath ten distinct stamina, which decline, four of which are longer than the rest, and are terminated by oblong incumbent summits. It hath a long slender germen,

men, sitting upon a slender style, crowned by an obtuse stigma; the germen afterward becomes an oblong pod with an oblique point, having one cell, inclosing several roundish compressed seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flower having ten stamina and one style. This genus is by all the writers placed with the papilionaceous flowers, before Linnæus's System, which separates it from them, because the stamina in these flowers are all distinct; whereas the papilionaceous flowers have nine stamina joined together, and one separate.

The SPECIES are,

1. CERCIS (*Silicuastrum*) foliis cordato-orbiculatis glabris. Hort. Cliff. 156. *Cercis* with round, heart-shaped, smooth leaves. *Silicuastrum*. Cast. Duran. 415. and the Arbor Judæ. Dod. Pemp. 786. *The common Judas-tree*.

2. CERCIS (*Canadensis*) foliis cordatis pubescentibus. Hort. Cliff. 156. *Cercis* with downy heart-shaped leaves. *Silicuastrum Canadense*. Tourn. Inst. R. H. 647. *Canada Arbor Judæ, or Red Bud-tree*.

The first sort grows naturally in the south of France, Spain, and Italy, and is by the Spaniards and Portuguese, titled the Tree of Love: this rises with an upright trunk to the height of twenty feet, covered with a dark brown bark, dividing upward into many irregular branches, garnished with round, heart-shaped, smooth leaves, placed irregularly on the branches, having long foot-stalks; they are of a pale green on their upper, and of a grayish colour on their under side, and fall off in autumn. The flowers come out on every side the branches, and many times from the stem of the tree in large clusters, arising from the same point, having short foot-stalks; they are of a very bright purple colour, so make a fine appearance, especially when the branches are covered pretty thick with them: for they come out in the spring with the leaves, so are in full beauty before the leaves have obtained to half their size. The shape of the flower is the same as other papilionaceous (or butterfly) flowers; these have an agreeable poignancy, so are frequently eaten in sallads. When the flowers fall off, the germen becomes a long flat pod with one cell, containing one row of roundish seeds, a little compressed; but these do not often succeed the flowers in this country upon standard trees, for the birds pick off the flowers when fully open; but where they have been planted against good aspected walls, I have seen great plenty of the pods, which, in warm seasons, have ripened very well.

These trees are usually planted with other flowering trees and shrubs for ornaments to pleasure-gardens, and for their singular beauty, deserve a place as well as most other sorts; for when they are arrived to a good size, they are productive of flowers, so as that the branches are often closely covered with them; and the singular shape of their leaves make a very pretty variety in the summer, and are seldom damaged by insects, so that they are often entire, when many other trees have their leaves almost eaten up. This tree flowers in May, when planted in the full air, but against warm walls it is a fortnight or three weeks earlier.

The wood of this tree is very beautifully veined with black and green, and takes a fine polish, so may be converted to many uses.

There are two other varieties of this tree, one with a white, and the other hath a flesh-coloured flower, but these have not half the beauty of the first. Tournefort also mentions one with broader pods and pointed leaves, which I believe is only a variety of this.

The second sort grows naturally in most parts of North America, where it is called Red Bud, I suppose from the red flower-buds appearing in the spring before the leaves come out; this grows to a middling stature in the places where it is a native, but in England rarely rises with a stem more than twelve feet high, but branches out near the root. The branches of this

are weaker than those of the first sort; the leaves are downy, and terminate in points; whereas those of the first are smooth, and round at the end where they are indented. The flowers of this are also smaller, so do not make so fine appearance as those of the first; but the trees are equally hardy, and will thrive in the open air very well.

The flowers of this sort are frequently put into sallads by the inhabitants of America; and the French in Canada pickle the flowers, but these have little flavour. The wood of this tree is of the same colour and texture as that of the first.

These plants may be propagated by sowing their seeds upon a bed of light earth, towards the latter end of March, or the beginning of April (and if you put a little hot dung under the bed, it will greatly facilitate the growth of the seeds;) when the seeds are sown, sift the earth over them about half an inch thick; and, if the season prove wet, it will be proper to cover the bed with mats, to preserve it from great rains, which will sometimes burst the seeds, and cause them to rot; the seeds will often remain till the spring following before they come up, so the ground must not be disturbed till you are convinced that the plants are all come up; for some few may rise the first year, and a greater number the second.

When the plants are come up they should be carefully cleared from weeds, and in very dry weather must be now and then refreshed with water, which will greatly promote their growth. The winter following, if the weather is very cold, it will be proper to shelter the plants, by covering them either with mats or dry straw in hard frosts, but they should constantly be opened in mild weather, otherwise they will grow mouldy and decay.

About the beginning of April, you should prepare a spot of good fresh ground, to transplant these out (for the best season to remove them is just before they begin to shoot;) then you should carefully take up the plants, being careful not to break their roots, and plant them as soon as possible, because if their roots are dried by the air, it will greatly prejudice them.

The distance these should be planted, must be proportionable to the time they are to remain before they are again transplanted; but commonly they are planted two feet row from row, and a foot asunder in the rows, which is full room enough for them to grow two or three years, by which time they should be transplanted where they are designed to remain; for if they are too old when removed, they seldom succeed so well as younger plants.

The ground between the plants should be carefully kept clean from weeds in summer, and in the spring should be well dug to loosen the earth, that their roots may extend themselves every way; at that season prune off all strong side branches (especially if you intend to train them up for standard trees,) that their top branches may not be checked by their side shoots, which often attract the greatest part of the nourishment from the roots; and if their stems are crooked, you must place a strong stake down by the side of each plant, and fasten the stem to it in several places, so as to bring it strait, which direction it will soon take as it grows larger, and thereby the plants will be rendered beautiful.

When they have remained in this nursery two or three years, they should be transplanted in the spring where they are designed to remain, which may be in wilderness quarters among other flowering trees, observing to place them with trees of the same growth, so as they may not be overhung, which is a great prejudice to most plants.

CEREFOLIUM. See CHÆREFOLIUM.

CEREUS. Par. Bat. 122. Boerh. Ind. alt. 1. 292. Juss. Act. R. Par. 1716. Cactus. Lin. Gen. Plant. 539. The Torch Thistle.

The CHARACTERS are,

It hath an oblong scaly empalement, which is covered with spines, and sits upon the germen. The flower is composed

M m m

of

of a great number of narrow pointed petals, which spread open like the sun's rays. It hath a great number of declining stamina, which are inserted to the base of the petals, and are terminated by oblong summits. The germen, which is situated under the empalement, supports a long cylindrical style, crowned with a multifid stigma, in form of a head. The germen afterward becomes an oblong succulent fruit, with a prickly skin, full of small seeds inclosed in the pulp.

Dr. Linnæus has joined the plants of this genus, and also those of Opuntia to the Cactus, making them only species of the same genus; but as the flowers of these plants differ greatly in their form from those of the Cactus, they should be separated; and by preserving the title to this genus, by which it has been long known, it will prevent confusion; and by increasing the number of genera, the specific differences may be better ascertained. Linnæus places the genus of Cactus in his twelfth class, intitled Icosandria, in which he includes those plants, whose flowers have from nineteen to thirty stamina, which are fastened to the petals.

The SPECIES are,

1. CEREUS (Hexagonus) erectus, sexangularis, longus, angulis distantibus. Upright long Cereus with six angles, which are far distant. Cereus erectus altissimis Surinamensis. Par. Bat. 116. Tallest upright Torch Thistle of Surinam.
2. CEREUS (Tetragonus) erectus quadrangularis, angulis compressis. Upright Cereus with four compressed angles. Cereus erectus quadrangularis, costis alarum instar assurgentibus. Boerh. Ind. alt. 293. Four-cornered upright Torch Thistle.
3. CEREUS (Lanuginosus) erectus octangularis, angulis obtusis, supernè inermibus. Upright Cereus with eight obtuse angles, having no spines on the upper part. Cereus erectus, fructu rubro non spinoso. Par. Bat. 114. Upright Torch Thistle with a red fruit, having no spines.
4. CEREUS (Peruvianus) erectus octangularis, angulis obtusis, spinis robustioribus patulis. Upright Cereus with eight angles which are obtuse, and strong spreading spines. Cereus erectus maximus fructu spinoso rubro. Dadus. Par. Bat. 113. Greatest upright Torch Thistle with a red prickly fruit.
5. CEREUS (Repandus) erectus novemangularis, obsoletis angulis, spinis lanâ brevioribus. Upright Cereus with nine angles, and spines shorter than the down. Cereus Curassavicus, erectus, maximus, fructu rubro non spinoso, lanugine flavescente. Par. Bat. 115. Greatest upright Torch Thistle with a red fruit, having no spines, and a yellowish down.
6. CEREUS (Heptagonus) erectus octangularis, spinis lanâ longioribus. Upright Cereus with seven or eight angles, and spines longer than the down. Cereus erectus crassissimus maximè angulosus, spinis albis pluribus longissimis, lanugine flavâ. Boerh. Ind. alt. 293. Upright thickest Torch Thistle, having many angles, several very long white spines, and a yellow down.
7. CEREUS (Royeni) erectus novemangularis, spinis lanâ æqualibus. Upright Torch Thistle with nine angles, and spines of equal length with the down. Cereus erectus, gracilis, spinosissimis, spinis flavis, polygonus, lanugine albâ pallecente. Boerh. Ind. alt. 293. Upright slender Torch Thistle, very full of yellowish spines, many angles, and a pale white down.
8. CEREUS (Gracilis) erectus gracilior novemangularis spinis brevibus, angulis obtusis. Slenderer upright Torch Thistle having nine obtuse angles, and short spines. Cereus altissimis, gracilior, fructu extus luteo intus nigro, seminibus nigris pleno. Tallest slender Torch Thistle with a fruit yellow without, white within, and full of black seeds.
9. CEREUS (Triangularis) repens triangularis, fructu maximo rotundo, rubro, esculento. Creeping triangular Torch Thistle, with very large, round, red, eatable fruit. Cereus scandens minor trigonus articulatis fructu suavissimo. Par. Bat. Prod. 118. Lesser, creeping, three-cornered, jointed Torch Thistle, with a very sweet fruit, commonly called in the West Indies, the true prickly Pear, and by the Spaniards Pitahaya.

10. CEREUS (Compressis) repens triangularis, angulis compressis. Creeping triangular Torch Thistle, with compressed angles. Ficoides Americanum, f. Cereus erectus, cristatus, foliis triangularibus profundè canaliculatis. Pluk. Phyt. tab. 29. f. 3. Crested American Torch Thistle, with three angles deeply channelled.

11. CEREUS (Grandiflorus) repens subquingularibus. Creeping Torch Thistle with five angles. Cereus scandens minor polygonus articulatis. Par. Bat. 120. Lesser jointed climbing Torch Thistle with many angles.

12. CEREUS (Flagelliformis) repens decemangularis. Creeping Cereus with ten angles. Cereus minor scandens, polygonus, spinosissimis, flore purpureo. Ed. Prior. Lesser climbing Torch Thistle, with many spinous angles and a purple flower.

The first sort has been the most common in the English gardens. This grows naturally in Surinam, from whence it was brought to the gardens in Holland, where it produced flowers in the year 1681, and from the Dutch gardens, most parts of Europe have been supplied with this plant.

This rises with an upright stalk, having six large angles, which are far asunder, armed with sharp spines, which come out in clusters at certain distances, arising from a point, but spread open every way like a star; the outer substance of the plant is soft, herbaceous, and full of juice, but in the center there is a strong fibrous circle running the whole length, which secures the stem from being broke by winds. These will rise to the height of thirty or forty feet, provided their tops are not injured, if they have room to grow; but some of them have grown too tall to be kept in the stoves, so have either been cut off, or the plants laid down at length in winter; but whenever the stems are cut, or otherwise injured, they put out one, two, or sometimes three shoots, from the angles, immediately under the wounded part, and frequently one or two lower down. These shoots, if they are not cut off, form so many distinct stems, and grow upright; but these seldom are so large as the principal stem, especially if more than one is left on the same plant. The flowers come out from the angles on the side of the stem; these have a thick, fleshy, scaly foot-stalk, round, channelled, and hairy, supporting a swelling germen, upon the top of which sits the scaly prickly empalement, closely surrounding the petals of the flowers, till a little time before they expand, which in most of the sorts is in the evening, and their duration is very short, for before the next morning they wither and decay. The flower of this sort is composed of many concave petals, which, when fully expanded, are as large as those of the Hollyhock; the inner petals are white, and crenated at their extremity. The empalement is green, with some purple stripes; the middle of the flower is occupied by a great number of stamina, which decline, and rise at their extremities, having roundish summits. The flowers of this kind are never succeeded by fruit in this country, nor do the plants often produce their flowers here; but when they do, there are generally several on the same plant. I have some years had more than a dozen upon a single plant, which have all flowered within a few days of each other. The usual time of its flowering is in July.

This sort is not so tender as the others, so may be preserved in a warm green-house, without any artificial heat; but the plants should have no water given them in winter, when they are thus situated; for unless they are placed in a stove, where the moisture is soon evaporated, the wet will occasion them to rot.

These plants naturally grow upon very dry rocky places, where their roots are confined, so they must not be planted in large pots, nor should they be planted in rich soil; the best compost for them is one third light earth from a common, a third of sea sand, and the other part sifted lime-rubbish; if these are well mixed together, and often turned over before the plants are put into it, they will thrive the better. The farther directions for their management, will be hereafter exhibited.

The

The second sort rises with an upright stem like the first, but it hath only four angles, which are compressed, and stand far asunder. This is very subject to put out many shoots from the sides, which stops its upright growth, so that the plants rarely rise more than four or five feet high. This hath not flowered in England, so far as I have been able to learn. The third, fourth, fifth, sixth, seventh and eighth sorts grow naturally in the British islands of America, from whence I received them in the year 1728. These have the same form as the first, but differ in the size of their stems, the number of angles, and the length of their spines, as is before expressed in their titles; but, except the eighth sort, not any of them have flowered in England as yet, though there are many of the plants which are more than twelve or fourteen feet high: the eighth sort hath the smallest stem of any of the upright sorts which I have yet seen; this hath generally nine obtuse angles, which are armed with short spines, placed at farther distances than those of the other sorts, nor are the channels between the angles near so deep. The flowers of this are produced from the angles, in the same manner as the first, but they are smaller, and the empalement is of a light green, without any mixture of colour. The fruit is about the size and shape of a middling Bergamot Pear, having many soft spines on the skin; the outside is a pale yellow, the inside very white, full of pulp, having a great number of small black seeds lodged in it. This sort frequently flowers in July, and in warm seasons will perfect its fruit, which hath very little flavour in this country.

These sorts are more impatient of cold than the first, so require a stove to preserve them in winter; nor should they be exposed abroad in summer, but kept constantly in the house, giving them a large share of air in warm weather.

The twelfth sort grows naturally in Peru, from whence it was sent to the royal garden at Paris; and in the year 1734, I was favoured with some cuttings of it by Dr. Bernard de Jussieu, demonstrator of the plants in that garden. These succeeded in the Chelsea garden, and have since been communicated to most of the curious gardens in England. This is not so tender as the other sorts, so may be preserved in a good green-house, or placed under a hot-bed frame in winter, and in summer should be exposed to the open air, which will prevent the shoots from drawing weak, and thereby a greater number of flowers will be produced; but during the time they remain in the open air, they should have little water; and if the season should prove wet, the plants should be screened from it, otherwise it will cause them to rot the following winter. This sort produces its flowers in May, and sometimes earlier, when the season is warm.

The ninth sort is, by the inhabitants of Barbadoes, trained up against their houses for the sake of its fruit, which is about the bigness of a Bergamot Pear, and of a most delicious flavour. This, and also the tenth, eleventh, and twelfth sorts, are tender, so require a warm stove to preserve them. These should be placed against the walls of the stove, into which they will insinuate their roots, and extend themselves to a great length; and with a little help, in fastening them to the wall in a few places, may be led up about the ceiling of the house, where they will appear very handsome. And the eleventh sort, when arrived to a sufficient strength, will produce many exceeding large, beautiful, sweet-scented flowers; but they are (like most of the flowers of these kinds) of very short duration, scarcely continuing full blown six hours; nor do the same flowers ever open again, when once closed: they begin to open in the evening between seven and eight of the clock, are fully blown by eleven, and by three or four the next morning fade, and hang down quite decayed; but, during their continuance, there is scarce any flower of greater beauty, or that makes a more mag-

nificent appearance; for the calyx of the flower, when open, is near a foot diameter; the inside of which, being of a splendid yellow colour, appears like the rays of a bright star, the outside of a dark brown; and the petals of the flowers being of a pure white, adds to the lustre; and the vast number of recurved stamina, surrounding the style in the center of the flower, make a fine appearance; and add to this the fine scent of the flower, which perfumes the air to a considerable distance: there is scarce any plant which deserves a place in the hot-house so much as this, especially as it is to be trained against the wall, where it will not take up room. The usual season of its flowering is in July, and when the plants are large, they will produce a great number of flowers, so that there will be a succession of them for several nights, and many of them will open the same night. I have frequently had six, eight, or ten flowers open at the same time upon one plant, which have made a most magnificent appearance by candle-light, but none of them have been succeeded by any appearance of fruit.

The tenth sort produces a flower little inferior to the former, as I have been informed by persons who have seen them; but I never had the good fortune to have any of these plants which have been under my care flower; nor have I heard of more than two gardens where they have as yet flowered in England; the first of them was many years since in the royal gardens at Hampton Court, when there was a curious collection of exotic plants kept in good order in those gardens, which have since been greatly neglected; the other was produced in the gardens of the right honourable the Marquis of Rockingham, at Wentworth-Hall, in Yorkshire. These are the only gardens in this country where I have heard of this sort having produced flowers; although there are many of these plants in several gardens, which are of a considerable age, and extend their branches to a very great distance.

The ninth sort has never produced any flowers as yet in England, nor have we any good figure of the flower in any of the botanic books; but I have been informed by some curious persons who have resided in America, that the flowers are not near so beautiful as those of the tenth and eleventh, but the fruit is greatly esteemed by all the inhabitants.

The twelfth sort produces a greater number of flowers than either of the other; these are of a fine Pink colour, both within and without; the petals are not so numerous, and the tube of the flower is longer than those of the other species; and, contrary to all the other sorts, keep open three or four days, provided the weather is not too hot, or the place where they stand kept too warm. During the continuance of these flowers, they make a fine appearance. This sort has very slender trailing branches, which require to be supported; but these do not extend so far as those of the other sort, nor are their branches jointed as those are, so they cannot be trained so far against the walls of the house; but as it produces such beautiful flowers, and in so great plenty, it may be placed among the first class of exotic plants. This plant has produced fruit in the garden at Chelsea, but it hath not as yet ripened.

These plants are all propagated by cuttings, so that if you intend to increase the number of them, you must cut off the stems of the upright sorts at what length you please; these should be laid in a dry place to heal the part cut, at least a fortnight or three weeks before they are planted; but if they lie a month it is much the better, and they will be in less danger of rotting, especially those sorts which are the most succulent.

These cuttings should be planted in pots filled with the mixture of earth before directed, laying some stones in the bottom of the pots to drain off the moisture; then place the pots into a gentle hot-bed of tanners bark, to facilitate their rooting, giving them once a week a gentle watering.

The

The best season for this work is in June, or the beginning of July, that they may have time to root before winter; towards the middle of August you must begin to give them air by degrees, to harden them against winter, but they should not be wholly exposed to the open air or sun; at the end of September they must be removed into the stove, or green-house, where they are to abide the winter, during which season you must be very careful not to let them have much water; and always observe to place the young plants, for the first winter, in a little warmer situation than the older plants, as being somewhat tenderer.

These plants should always have a dry situation in winter, for as they imbibe the greatest part of their nourishment from the circumambient air, so if this be too replete with moist particles, it will occasion their rotting; therefore they should not be exposed abroad, not even in the midst of summer, -unless they are under shelter; for great rains, which often happen at that season, are very injurious to them; the first eight sorts should be therefore placed so as to enjoy a free air in the summer, but, at the same time, screened from rains and great dews; it will therefore be much the better method to set them in an open glass stove, where the windows may be set open in good weather, and shut in cold or wet. The other four sorts must not be exposed too much to the open air, even in the hottest season, especially if you design to have them flower; and in winter they should be kept very warm, and have no water given them.

When you have once cut off the tops of any of these plants, in order to increase them, the lower parts will put forth fresh shoots from their angles, which, when grown to be eight or nine inches long, may also be taken off to make fresh plants; and, by this means, the old plants will continually afford a supply, so that you never need cut off above one plant of a sort, which you should preserve for a breeder.

These plants being succulent, they will bear to be a long time out of the ground; therefore whoever hath a mind to get any of them from the West Indies, need give no other instructions to their friends, but to cut them off, and let them lie two or three days to dry; then put them up in a box with dry hay, or straw, to keep them from wounding each other with their spines, and if they are two or three months on their passage, they will keep very well, provided no wet get to them.

CERINTHE. Lin. Gen. Plant. 171. Tourn. Inst. R. H. 79. tab. 16. Honeywort; in French, *Melinet*.

The CHARACTERS are,

It hath an oblong permanent empalement, cut into five equal parts. The flower hath one petal, having a thick short tube, which swells upward much thicker, and at the brim is quinquesid; the chaps are naked and pervers; it hath five short stamina, terminated by pointed upright summits. In the bottom are situated four germen, supporting a slender style the length of the stamina, crowned by an obtuse stigma; two of the germen afterward becomes so many seeds, which are hard, smooth, plain on one side, but convex on the other, and are inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. CERINTHE (*Major*) foliis ovato-oblongis, asperis, amplexicaulibus, corollis obtusiusculis, patulis. *Honeywort with oval, oblong, rough leaves, embracing the stalk, and spreading blunt petals. Cerinthe quorundam major, spinoso folio, flavo flore. J. B. 3. 602. Greater Honeywort with a prickly leaf, and a yellow flower.*
2. CERINTHE (*Glabris*) foliis oblongo-ovatis, glabris, amplexicaulibus, corollis obtusiusculis, patulis. *Honeywort with oblong, oval, smooth leaves, embracing the stalks, and a spreading blunt petal. Cerinthe flore rubro*

purpurascens. C. B. P. 258. Honeywort with a purplish red flower.

3. CERINTHE (*Minor*) foliis amplexicaulibus, integris, fructibus geminis, corollis acutis, clausis. Lin. Sp. Plant. 137. *Honeywort with entire leaves, embracing the stalk, a double fruit, and a pointed closed petal. Cerinthe minor. C. B. P. 258. Smaller Honeywort.*

The first sort grows naturally in Germany and Italy. This is an annual plant, which rises with smooth branching stalks a foot and a half high, garnished with oval, oblong, prickly leaves; which are of a sea-green, spotted with white, and embrace the stalks with their base; the flowers are produced at the end of the branches, standing between the small leaves, which embrace the stalks; these are long, tubulous, and blunt at the top, where the tube is greatly enlarged; they are yellow, and have a mellous liquor in their tubes, with which the bees are much delighted; and an herbaceous empalement, cut into five parts, which afterward incloses the seeds; these flowers have each four embryos, or germen, but only two of them are fruitful. The top of the stalks are reflexed backward, somewhat like those of Turnsole. It flowers in June and July, and the seeds ripen in August and September. If the seeds are not taken as soon as they change black, they drop out of the empalement in a short time; so unless they are carefully gathered up, they will vegetate with the first moist weather.

The second sort is like the first, but the leaves are larger, and smooth, having no prickles on them. The flowers of this are of a purplish red colour, and the plants grow larger. This grows in Italy, and the south of France; it is also an annual plant.

The third sort grows naturally on the Alps, and other mountainous places; this hath slenderer stalks than either of the former, which rise two feet high, and closer garnished with leaves than either of the others; these embrace the stalks with their base, and are of a bluer green colour. The flowers are small, their upper part is deeply cut into five segments, but the mouth of the tube is closely shut up; the empalement is large, and closely surrounds the flower. The flowers are yellow, and appear at the same time with the other sorts. If the seeds of this are permitted to scatter, the plants will come up in autumn, and these will grow much taller, and flower earlier than those which are sown in the spring; this hath been supposed a perennial plant by many, but from many years observation, I could never find these plants continue after they had flowered and perfected their seeds.

The species of this plant are propagated by seeds, which should be sown soon after they are ripe; for, if they are kept till spring, the growing quality of them is often lost; or at least they lie some months in the ground before they grow; the plants are hardy, and if the seeds are sown in a warm situation, they will endure the winter's cold very well without shelter; these autumnal plants are also much surer to produce ripe seeds than those which are sown in the spring, which are generally late in the season before they flower; and consequently if the autumn should not prove very warm, their seeds would not be perfected.

The plants make a pretty variety for large borders in gardens, where, if they are suffered to drop their seeds, the plants will arise without any farther care; so that when a person is once furnished with the several varieties, he need be at no more trouble than to allow each of them a respective place where it may remain, and sow itself; and with this culture, there is a greater certainty of preserving the sorts than in any other management; nor will they perhaps be entirely lost in this way, if it should happen that the season should prevent their ripening seed (as it sometimes proves;) for when great quantities of the seeds have scattered upon the ground, some of them will be buried so deep, in stirring the earth, as not to grow the first year; which, upon being turned up to

to the air the succeeding year, will come up as well as new seeds.

CESTRUM. Lin. Gen. Plant. 231. Jasminoides. Dill. Nov. Gen. 170. Bastard Jasmine.

The CHARACTERS are,

It hath a short tubular empalement of one leaf, which is indented at the top into five parts, which are erect. The flower is funnel-shaped, of one petal, having a long cylindrical tube, which spreads open at the top, where it is cut into five equal segments; it hath five slender stamina the length of the tube, to which they adhere, and are terminated by roundish four-cornered summits. The oval cylindrical germen is situated in the empalement, supporting a slender style the length of the stamina, crowned by an obtuse thick stigma. The germen afterward becomes an oval oblong berry with one cell, inclosing several roundish seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. **CESTRUM** (*Nocturnum*) floribus pedunculatis. Hort. Cliff. 490. *Cestrum with flowers standing upon foot-stalks. Jasminoides foliis Pishaminis, flore virecente noctu odoratissimo.* Hort. Elth. 183. tab. 153. *Bastard Jasmine with leaves of Pishamin, and a greenish flower, smelling very sweetly in the night.*
2. **CESTRUM** (*Diurnum*) floribus sessilibus. Hort. Cliff. 491. *Cestrum with flowers growing to the branches. Jasminoides laureolæ folio, flore candido interdum odorato.* Hort. Elth. 186. tab. 154. *Bastard Jasmine with a Spurge Laurel leaf, and a white flower, smelling in the day.*
3. **CESTRUM** (*Nervosum*) foliis lanceolatis oppositis nervis transversalibus, pedunculis ramosis. *Cestrum with spear-shaped leaves growing opposite, having transverse veins, and branching foot-stalks to the flowers. Jasminoides Americanum, lauri folio, flore albo odorato.* Hoult. MSS. *Bastard Jasmine of America with a Bay leaf, and a white, sweet, smelling flower.*
4. **CESTRUM** (*Spicatum*) foliis ovato-lanceolatis, floribus spicatis, alaribus & terminalibus. *Cestrum with oval spear-shaped leaves, and flowers growing in spikes from the sides and tops of the branches.*
5. **CESTRUM** (*Confertum*) foliis oblongo-ovatis, obliquis, floribus alaribus confertis, tubo longissimo & tenuissimo. *Cestrum with oblong oval leaves which are oblique, and flowers growing in clusters from the sides of the branches, with a very long slender tube.*
6. **CESTRUM** (*Venenatum*) foliis lanceolatis obliquis, floribus alaribus, pedunculis foliosis. *Cestrum with oblique spear-shaped leaves, flowers proceeding from the sides of the branches, and leafy foot-stalks. Jasminum laurinis foliis, flore pallide luteo, fructu atrocæruleo polypireno venenato.* Sloan. Hist. Jam. 2. p. 196. *Jasmine with Bay leaves, a pale yellow flower, and a dark blue fruit with many seeds, which are poisonous.*

The first sort was many years past raised in the curious gardens of the Dukes of Beaufort, at Badmington, in Gloucestershire, and was from thence communicated to several gardens in England and Holland, where in the latter it passes under the title of Badmington Jasmine to this time. This grows naturally in the island of Cuba, from whence I received the seeds by the title of Dama de Noche, i. e. Lady of the Night; which appellation I suppose was given it, from the flowers sending out a strong odour after the sun is set.

It rises with an upright stalk about six or seven feet high, covered with a grayish bark, and divides upward into many slender branches, which generally incline to one side; and are garnished with leaves placed alternate, which are near four inches long, and one and a half broad, smooth on their upper side, of a pale green, and on their under side they have several transverse veins, and are of a sea-green colour, having short foot-stalks. The flowers are produced at the wings of the leaves, in small clusters, standing upon short foot-stalks, each sustaining four or five

flowers, which have very short empalements, with long slender tubes, which are enlarged at the top, where they are cut into five parts which are reflexed; these are of an herbaceous colour; they appear in August, but are not succeeded by berries in this country; but those which I received from America were small, and of a dark brown colour, inclosing several seeds.

The seeds of the second sort were sent me from the Havannah, by the title of Dama de Dio, or Lady of the Day; this rises with an upright stalk to the height of ten or twelve feet, covered with a smooth light green bark, dividing upward into many smaller branches, garnished with smooth leaves near three inches long, and one and a half broad, of a lively green colour, and the consistence of those of the Spurge Laurel; these are ranged alternately on the branches. Toward the upper part of the shoots come out the flowers from the wings of the leaves, standing in clusters close to the branches; they are very white, shaped like those of the former sort, and smell sweet in the day time, from whence it had the appellation of Lady of the Day. The berries of this are smaller than those of the first sort. This flowers in September, October and November.

The third sort was sent me from Carthage in New Spain, near which place it grows naturally; this rises with a shrubby stalk five or six feet high, covered with a brown bark, and divides upward into many small branches, garnished with spear-shaped leaves, about four inches long, and little more than one broad; they are smooth, of a light green, and have many horizontal veins running from the midrib to the sides, and are placed opposite. From the wings of the leaves, toward the upper part of the branches, are produced the flowers, standing upon branching foot-stalks, each sustaining four or five flowers, whose tubes are swelling at their base, just above the empalement, but contract upward to the mouth, where the petal is cut into five broad segments which spread flat; they are white, but without scent.

The fourth sort was sent me from Carthage with the former. This rises with a shrubby stalk ten or twelve feet high, covered with a light gray bark, and sends out many branches the whole length, garnished with oval spear-shaped leaves, standing without order; they are two inches and a half long, and one and a half broad, of a light green, with slender foot-stalks. The flowers come out in loose spikes from the side, and also the end of the branches, which are shaped like those of the first sort, and are of a whitish green colour, without scent. These are succeeded by roundish purple berries, the size of large Pease, which have a soft juicy pulp, filled with flat seeds.

The fifth sort rises with several shrubby stalks eight or ten feet high, covered with a white smooth bark, sending out many irregular branches, garnished with oblong oval leaves, which at their base are longer on one side, so that the foot-stalk is oblique; they are placed on the branches without order, and are of a pale green. The flowers come out in clusters from the side of the branches, many of them arising from the same point; these have very slender long tubes, which are cut at the top into five acute segments which are erect. They are of a pale yellow, and without scent.

The sixth sort grows naturally in Jamaica, from whence it was sent me by the late Dr. Houlstoun. This rises with a woody stem eight or nine feet high, covered with a smooth brown bark, and sends out many branches on the side which grow erect, garnished with oval spear-shaped leaves, whose foot-stalks are short; they are five inches long, and two broad, smooth, of the consistence with Bay leaves, and are placed alternate on the branches. From the wings of the leaves the flowers are produced, most part of the length of the branches; the foot-stalks of the flowers are garnished with small leaves, standing between each flower in a singular manner, the flowers

N n n

rising

rising one above the other; and between, or opposite to each, is one, and sometimes two leaves, of the same form with those on the branches. The flowers are of a pale yellow, and emit a disagreeable odour. These are succeeded by oval berries of a Violet colour, full of juice, each containing several flat seeds; they are reckoned very poisonous, so have the appellation of Poison Berries in Jamaica.

This has been, by many of the writers on botany, supposed to be the same with the first; but any person who has seen both sorts growing, cannot doubt of their being distinct species; the shape and size of the leaves are very different, as are also their flowers and berries. Some have also supposed that the Parqui of Pere Feuillé, is the same with this, but that is a great mistake; for the flowers of this plant are produced in loose bunches at the extremity of the branches, whereas those of this sort come out from the side, at the foot-stalks of the leaves; so that this plant is certainly different from either of these, but approaches nearest to the third.

The fifth sort I take to be the same as Pere Plumier's *Jasminum aliud arborescens, foliis solani, minus*; for by an imperfect specimen of his plant which was shewn me, the leaves appear the same, but as the specimen was without flower or fruit, so I could not determine it.

The first and second sorts produce their flowers every year in England, but the others do but seldom flower here; but as they retain their leaves all the year, so they make a pretty variety in the stove, during the winter season; and when they flower, the branches are commonly well garnished at their joints with bunches of flowers, so they make a fine appearance at that time.

All these plants grow naturally in very hot countries, so cannot be preserved in England without artificial heat; therefore require to be placed in a warm stove, especially in the winter. The two first are hardier than the others; these I have kept several years in a dry stove, with a moderate share of heat in winter, and in the middle of summer have set them in the open air, in a warm situation. With this management I have found them thrive, and produce flowers much better than when they have been placed in a greater heat; but I have often endeavoured to keep these plants through the winter, in a green-house, or a glass case, without fire, but could never succeed; for by the end of January, they commonly decayed.

The other sorts require a larger share of heat, especially when the plants are young; therefore they should be plunged in the tan-bed of the bark-stove, otherwise they will lose their leaves in winter, if they are not quite destroyed; but after three or four years growth, they will bear to be treated more hardily, provided they are inured to it gradually.

These plants may be propagated from seeds, or by cuttings. Those which come from seeds are always the most vigorous, and straitest plants; but as they do not produce seeds in England, so the other method is generally practised, because their seeds are rarely brought hither.

The best time to plant these cuttings is about the end of May, by which time the shoots will have had time to recover their strength, after their confinement during the winter season. The shoots which come out from the lower part of the stalks, should always be chosen for this purpose. These should be cut about four inches long, and five or six of them may be planted in each halfpenny pot; for the cuttings of most sorts of exotic plants, will succeed better when they are planted in these small pots, than they do in larger, as I have many years experienced. The earth in which these are planted, should be fresh and light, but not full of dung: when the cuttings are planted, the earth must be pressed pretty close to them, and then gently watered; after which the pots must be plunged into a moderate hot-bed of tanners bark, and every day shaded from the sun. They must also have

fresh air admitted to them in warm weather, and two or three times a week refreshed with water. With this management the cuttings will put out roots in five or six weeks, when they should be gradually exposed to the sun; and when they begin to put out shoots, they must have a greater share of fresh air admitted to them, to prevent their drawing up weak; and their waterings should be oftener repeated, but given in small quantities, for their young tender fibres will not endure much wet. When they have made good roots, they should be carefully shaken out of the pots, and each put into a separate small pot, filled with the same sort of earth as before; then give them some water, to settle the earth to their roots, and plunge them again into the tan-bed; observing if any of their leaves hang down, to shade them from the sun in the middle of the day, until they have taken fresh root; after which they should have a large share of air in warm weather, to strengthen them before winter. Their waterings in the summer should be frequent; and if they are sprinkled all over their leaves, it will wash and cleanse them from filth, which will greatly promote their growth; but their roots must not be kept too moist.

In the autumn the plants of the three last sorts must be removed into the bark-stove, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotic plants; but the two first sorts may be treated otherwise, especially when they have obtained strength, yet the first winter they may be managed in the same way as the others. There must be great care had in watering of these plants in winter, for they are all (except the second sort) very impatient of moisture; so that they are soon killed by being over-watered.

If the seeds of these are procured from the countries where they grow naturally, they should be sowed in small pots filled with the earth before directed, and plunged into a moderate hot-bed of tanners bark, giving them now and then a little water. Sometimes the seeds will come up the same year, but they very often lie in the ground till the spring following; so that if the plants do not appear in six or seven weeks after the seeds are sown, they will not come up that season; in which case the pots may be plunged in the tan-bed of the stove, between the other plants, where they will be shaded from the sun, and but little water given them; in this situation they may remain till the following spring, when they should be removed, and plunged into a fresh hot-bed, which will bring up the plants in a short time, provided the seeds were good.

When the young plants are fit to remove, they should be carefully shaken out of the pots, and each planted into a separate pot filled with the before-mentioned earth, and plunged into the hot-bed again, and afterward treated in the same way as hath been directed for the plants raised from cuttings.

CHÆROPHYLLUM. Lin. Gen. Plant. 320. Tourn. Inst. R. H. 314. tab. 166. [*χαίρω*, to rejoice, and *φύλλον*, Gr. a leaf, because the leaves, steeped in wine, and drank, will exhilarate and cheer melancholy persons.] Chervil.

The CHARACTERS are,

It is an umbelliferous plant; the principal umbel is spreading and hath no involucre, composed of several small ones, called rays; the small ones have a five-leaved involucre, which is reflexed; the flowers have five heart-shaped inflexed petals, and five stamina, which are terminated by roundish summits: the germen is situated below the flower, supporting two reflexed styles, crowned with obtuse stigmas. The germen afterward becomes an oblong pointed fruit, dividing in two parts, each having one seed, which is convex on one side and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flowers having five stamina and two styles.

The

The SPECIES are,

2. CHÆROPHYLLUM (*Bulbosum*) caule lævi, geniculis tumidis. Lin. Sp. Plant. 258. *Chervil with a smooth stalk, and swelling joints.* Myrrhis tuberosa & nodosa conyophillon. Mor. Umb. 67. *Tuberous and knotted Myrrh with a Hemlock leaf.*
3. CHÆROPHYLLUM (*Temulum*) caule scabro, geniculis tumidis. Lin. Sp. Plant. 258. *Chervil with a rough stalk, and swelling joints.* Chærophylum sylvestre. C. B. P. 152. *Wild Chervil.*
4. CHÆROPHYLLUM (*Aureum*) caule æquali, foliolis incisis acutis. Lin. Sp. Plant. 258. *Chervil with an equal stalk, and leaves cut into acute segments.* Myrrhis perennis alba minor, foliis hirsutis, semine aureo. Mor. Umb. 282.
5. CHÆROPHYLLUM (*Hirsutum*) caule æquali, foliolis incisis acutis, feminibus subulatis. Lin. Sp. Plant. 371. *Wild Chervil with an equal stalk, whose small leaves are cut acutely, and awl-shaped seeds.* Myrrhis palustris, latifolia rubra. C. B. P. 161.

The first sort grows naturally on the side of highways, and the borders of the fields in most parts of England, so is never cultivated in gardens. It is frequently called Cow Parsley, but for what reason I cannot say, because there are few animals who care to eat it, except the ass; for it is reckoned to have something of the quality of Hemlock, but in a less degree. It is a weed which should be rooted out from all pastures in the spring, for it is one of the most early plants in shooting; so that by the beginning of April the leaves are near two feet high. The seeds of this plant spread greatly over the ground, and as the roots are perennial, they are often very troublesome weeds to destroy.

The second sort grows naturally in Hungary and Istria. This plant hath a thick tuberous root, from which come forth several leaves resembling those of Wild Chervil, which spread horizontally near the ground. The stalks rise six or seven feet high, which are spotted with purple, and garnished with leaves of the same form as those below. The knots at the joints of the stalks swell out on every side, at which is placed one of these divided leaves; the stalks are terminated by small umbels of white flowers, which are succeeded by long narrow seeds. It flowers in June, and the seeds ripen in August. If the seeds of this plant are permitted to scatter, the plants will come up without any farther care, and only require to be kept clean from weeds.

The third sort grows naturally on the sides of foot-walks, and on the borders of woods in many parts of England, so is not cultivated in gardens.

The fourth sort grows naturally in the pastures about Geneva, and in Switzerland; this hath a perennial root, from which come out in the spring many leaves, shaped like those of the first, but narrower, hairy, and more divided. The stalks are channelled, and rise three feet high, garnished with the like leaves; these are terminated by large umbels, formed of many small ones, which are composed of flowers, having five heart-shaped petals, which turn inward; these are succeeded by long pointed seeds. The whole plant has an aromatic smell and taste.

The fifth sort grows naturally on the Alps, and the Helvetian mountains. It is a perennial plant, somewhat resembling the first sort, but their leaves are hairy, and their segments are broader; the stalk rises four feet high, terminated by large umbels of flowers, which in some plants are red, and in others white; these are succeeded by long pointed seeds, two being joined in the same cover.

These plants are preserved in botanic gardens for variety; but as their use either in medicine or the kitchen are not known, they are rarely admitted into other gardens.

CHAMÆROPS. Lin. Gen. Plant. 1084. Chamæriphe. Pont. 10. Dod. Pempt. 820. Dwarf Palm, or Palmetto.

The CHARACTERS are,

It hath male and hermaphrodite flowers in distinct plants; the hermaphrodite flowers are all included in one common spathe or hood, which is compressed and bifid, and the spadix or club is branching; each flower hath a small three-pointed empalement; they have one thick upright petal, which is cut into three parts, and turns inward at the top, and five compressed stamina which join at their base, terminated by narrow twin summits, joined to the interior part of the stamina. They have three roundish germen, each having a distinct style, which is permanent, terminated by pointed stigma. The three germen afterwards become so many round berries, having one cell, each containing a single seed. The male flowers are like the hermaphrodite, but the stamina are not distinct, nor have they any germen.

This genus of plants is joined with the other kinds of Palms by Dr. Linnæus, and placed in the appendix to his Genera Plantarum; but should be ranged in his twenty-third class, or rather made a distinct class by themselves, because their manner of fructification is very different from most other plants.

The SPECIES are,

1. CHAMÆROPS (*Humilis*) frondibus palmatis, plicatis, stipitibus spinosis. Hort. Cliff. 482. *Dwarf Palm with folding palmated leaves, and prickly foot-stalks.* Palma humilis, sc. Chamæriphe. J. B. Hist. 1. 368. *Dwarf Palm, or Palmetto.*
2. CHAMÆROPS (*Glabra*) foliis flabelliformibus, maximis, stipitibus glabris. *Dwarf Palm with very large fan-shaped leaves, and smooth foot-stalks.* Palma non spinosa humilima. *Dwarf Palm without spines, commonly called small Palmetto Royal.*

The first sort grows naturally in Spain, particularly in Andalusia, where, in the sandy land, the roots spread and propagate so fast, as to cover the ground in the same manner as the Fern in England. The leaves of these plants are tied together to make beams for sweeping.

This never rises with an upright stem, but the foot-stalks of the leaves rise immediately from the head of the root, and are armed on each side with strong spines; they are flat on their upper surface, and convex on their under side. The center of the leaves are fastened to the foot-stalk, which spread open like a fan, having many foldings, and at the top are deeply divided like the fingers of a hand; when they first come out, they are closed together like a fan when shut, and are fastened together by strong fibres which run along the borders of the leaves; and when the leaves spread open, these fibres or strings hang from the sides and ends; the borders of the leaves are finely sawed, and have white narrow edgings; they are from nine to eighteen inches long, and near a foot broad in their widest part: as the lower leaves of the plants decay, their vestiges remain, and form a short stump above ground, in the same manner as our common male Fern does; from between the leaves comes out the spadix or club, which sustains the flowers; this is covered with a thin spathe or hood, which falls off when the bunches open and divide.

vide. As all the plants of this sort which I have seen flower were male, I cannot give any particular description of their fructification.

This plant is commonly propagated here by heads, which sometimes separate from the main root; if these are carefully taken off with fibres and planted, they will grow; but the plants so raised are not so good as those which are produced from seeds; so that if good seeds can be procured, that is by much the better way to propagate them. The seeds should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark; these must be refreshed now and then with water. If the seeds are fresh, the plants will come up in two months; these rise with a single long-pointed leaf. When they appear they must be now and then refreshed with water, but they must not have it in too great plenty. If the plants are not too close to each other in the pots, they will not require to be transplanted the first year; therefore they should remain in the tan-bed all the summer, but in warm weather they must have plenty of air admitted to them. In autumn the pots should be removed into the stove, and, if they are plunged into the bark-bed the first winter, it will greatly forward the growth of the plants. The following spring the plants should be carefully turned out of the pots, so as to preserve their roots entire; for all the sorts of Palms have tender roots, which, if they are cut off or broken, frequently kill the plants: then they should be each planted into a separate small pot filled with light, sandy, undunged earth, and plunged into a fresh hot-bed to encourage their taking root; the following summer they should be gradually hardened, by raising the glasses pretty high, so as to admit a large share of air to them, but they should not yet be wholly exposed to the open air. The autumn following the plants may be placed in a dry stove; but as the plants advance and get strength, they may be treated more hardily, and in summer placed in the open air in a warm situation, and in winter may be preserved in a warm green-house without artificial heat.

As the plants advance in growth, they should be put into larger pots; but when this is done, there must be great care taken, that their roots are not cut or broken, nor should they have pots too large. In winter they must have but little water, and if they are exposed to the open air in summer, they will not require much, unless the season proves very warm and dry, in which case they may be sparingly watered two or three times a week.

The second sort grows naturally in the West Indies, where it never rises with a stem; the foot-stalks of the leaves are rounder than those of the former, and have no spines on their sides. When the plants are old their leaves are three or four feet long, and upward of two broad; these are folded in the same manner as those of the first, but the folds are broader, and the leaves are of a darker green; some of these plants have put out slender bunches of male flowers in England, which were too imperfect to form a description.

This sort rises freely from seeds, which may be easily procured from the islands in America; these must be sown in the same manner as the former, and the plants treated in the same way; but as they are natives of a warmer climate, they should be constantly kept in the bark-stove, where, if they are carefully managed, they will make good progress.

I have received seeds from Carolina of a Dwarf Palm, which is very like this, if not the same; but the plants do not make so good progress here, as those which came from Jamaica; the berries were so like, that I could not distinguish them; but as the plants advance, if they are different, it will appear.

CHEIRANTHUS. Lin. Gen. Plant. 730. Leucojum. Tourn. Inst. R. H. 220. tab. 107. Stock Gilliflower and Wall-flower, in French *Giroffier ou Violier*.

The CHARACTERS are,

It hath a four-leaved compressed empalement; the two outer leaves are swelling at their base. The flower hath four petals placed in form of a cross; these are longer than the empalement. It hath six parallel stamina, which are the length of the empalement, two of which are between the swelling leaves of the empalement, the other are a little shorter, and are terminated by erect bifid summits, which are reflexed at the top. It hath a four-cornered prismatic germen as long as the stamina, supporting a very short compressed style, crowned with an oblong divided stigma, which is reflexed and permanent. The germen afterward becomes a long compressed pod with two cells, opening with two valves, filled with compressed seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetrandynamia filiquosa, the flowers having two long and four shorter stamina, and the seeds are lodged in long pods.

The SPECIES are,

1. CHEIRANTHUS (*Erysimoides*) foliis linearilanceolatis dentatis caule recto, filiquis tetragonis. *Cheiranthus with narrow, indented, spear-shaped leaves, an upright stalk, and four-cornered pods. Hesperis leucoii folio serrato, filiquâ quadrangulâ. Tourn. Inst. R. H. 223. Dames Violet with a sawed Wall-flower leaf, and a quadrangular pod.*
2. CHEIRANTHUS (*Integerrimis*) foliis lanceolatis integerrimis, caule erecto, filiquis tetragonis. *Cheiranthus with spear-shaped entire leaves, an upright stalk, and quadrangular pods. Hesperis leucoii folio non serrato, filiquâ quadrangulâ. Tourn. Inst. R. H. 223. Dames Violet with a Wall-flower leaf not sawed, and a quadrangular pod.*
3. CHEIRANTHUS (*Cheiri*) foliis lanceolatis, acutis, glabris ramis angulatis. Hort. Cliff. 334. *Cheiranthus with spear-shaped, pointed, smooth leaves. Leucojum luteum vulgare. C. B. P. Common yellow Leucojum, or Wall-flower.*
4. CHEIRANTHUS (*Angustifolium*) foliis linearibus, unguibus petalorum calyce longioribus. *Cheiranthus with narrow leaves, and the necks of the petals longer than the empalement. Leucojum angustifolium Alpinum flore sulphureo. H. R. Par. Narrow-leaved Wall-flower of the Alps, with a sulphur-coloured flower.*
5. CHEIRANTHUS (*Annuus*) foliis lanceolatis, subdentatis, obtusis, incanis, filiquis cylindricis apice acutis, caule herbaceo. Lin. Sp. Plant. 662. *Cheiranthus with spear-shaped leaves somewhat indented, obtuse, and hoary cylindrical pods, with acute points and an herbaceous stalk. Leucojum incanum minus. C. B. P. 200. Lesser hoary Stock Gilliflower, commonly called the Ten Weeks Stock.*
6. CHEIRANTHUS (*Incanus*) foliis lanceolatis, integerrimis, obtusis, incanis, filiquis apice truncatis, compressis, caule suffruticoso. Hort. Upsal. 187. *Cheiranthus with very entire spear-shaped leaves, which are obtuse and hoary, compressed pods with truncated points, and a shrubby stalk. Leucojum incanum majus. C. B. P. 200. Greater hoary Stock Gilliflower, commonly called the Queen's Stock Gilliflower.*
7. CHEIRANTHUS (*Coccineus*) foliis lanceolatis undatis, caule erecto indiviso. *Cheiranthus with waved spear-shaped leaves, and an upright undivided stalk. Leucojum incanum majus Coccineum. Mor. Hist. 2. 240. Greater hoary Stock Gilliflower with a scarlet flower, commonly called the Brompton Stock Gilliflower.*
8. CHEIRANTHUS (*Albus*) foliis lanceolatis, integerrimis, obtusis, incanis, ramis floriferis axillaribus, caule suffruticoso. *Cheiranthus with hoary, entire, spear-shaped, obtuse leaves, flower branches proceeding from the sides, and a shrubby stalk. Leucojum album five purpureum five violaceum. Ger. The white, purple, or Violet Stock Gilliflower.*
9. CHEIRANTHUS (*Glabrus*) foliis lanceolatis, acutis, petiolatis, viridibus, caule suffruticoso. *Cheiranthus with spear-shaped acute leaves, which are green, having foot-stalks, and a shrubby stalk. Leucojum album odoratissimum, folio viridi. C. B. P. 2. 102. Sweetest white Stock Gilliflower with a green leaf, commonly called white Wall-flower.*

10. CHEIRAN-

10. CHEIRANTHUS (*Senistalis*) foliis conferto-capitatis, recurvatis, undatis. Lin. Sp. Plant. App. 1198. *Cheiranthus with leaves growing close together in heads, which turn backward, and are waved.*
 11. CHEIRANTHUS (*Littoreus*) foliis lanceolatis, subdentatis subtomentosis subcarnosis, petalis emarginatis, siliquis tomentosis. Lin. Sp. 925. *Cheiranthus with spear-shaped, indented, woolly leaves, emarginated petals, and woolly pods. Leucojum maritimum angustifolium. C. B. P. 221. Narrow-leaved Sea Stock Gilliflower.*
 12. CHEIRANTHUS (*Maritimus*) foliis lanceolatis acutiusculis, caule diffuso, antheris eminentibus. Amœn. Acad. 4. p. 280. *Cheiranthus with acute spear-shaped leaves, a diffused stalk, and eminent anthers. Hesperis maritima, lupina, exigua. Tourn. Inst. 223. Small, low, maritime Dames Violet, commonly called Dwarf, or Virginia Stock Gilliflower.*
 13. CHEIRANTHUS (*Chius*) foliis obovatis aveniis emarginatis, siliquis apice subulatis. Hort. Upsal. 187. *Cheiranthus with oval emarginated leaves and pods, whose summits are awl-shaped. Hesperis siliquis hirsutis flore parvo rubello. Hort. Elth. 180. tab. 147. Dames Violet with hairy pods, and a small reddish flower.*
 14. CHEIRANTHUS (*Tricuspidatus*) siliquarum apicibus tridentatis foliis lyratis. Hort. Cliff. 335. *Cheiranthus with pods indented in three parts at the point, and lyre-shaped leaves. Hesperis maritima latifolia siliquâ tricuspidæ. Tourn. Inst. R. H. 223. Broad-leaved maritime Dames Violet, with a three-pointed pod.*
 15. CHEIRANTHUS (*Sinuatis*) foliis tomentosis obtusis subsinuatis, ramis integris, siliquis muricatis. Lin. Sp. 926. *Cheiranthus with woolly, obtuse, sinuated leaves, intire branches, and rough pods. Leucojum maritimum sinuato folio. C. B. P. 200.*
 16. CHEIRANTHUS (*Tristis*) foliis linearibus subsinuatis, floribus sessilibus petalis undatis, caule suffruticoso. Lœfl. *Cheiranthus with linear indented leaves, flowers close to the stalk, waved petals, and a shrubby stalk. Leucojum minus brevior folio, obsolete flore. Barrel. It. 999.*
 17. CHEIRANTHUS (*Lacerus*) foliis lacero-dentatis acuminatis, calycibus pilosis, siliquis nodosis mucronatis. Lin. Sp. 926. *Cheiranthus with torn, indented, pointed leaves, hairy empalements, and knobbed, acute-pointed pods. Leucojum Lusitanicum purpureum, foliis eleganter dentatis. Parad. Bat. 193.*
- The first sort grows naturally in the south of France, in Spain and Italy; this is an annual plant, which rises a foot high, with an angular channelled stalk, which branches upward on every side; these are garnished with long, narrow, green leaves, resembling those of the common Wall-flower, but are sharply indented on their edges, sitting close to the stalks; at the extremity of the branches the flowers are produced in loose spikes; these are yellow, having four petals situated in form of a cross, greatly resembling those of the common yellow Wall-flower, but have no scent; these are succeeded by long four-cornered pods, filled with brown seeds. It flowers in June, and the seeds are ripe in autumn.
- The second sort grows naturally in Hungary and Istria; this is also an annual plant, rising with an upright stalk nearly the same height as the other, but doth not branch out as that doth. The leaves are broader, smoother, and not pointed as those of the other; they stand alternately on the stalk without any visible foot-stalk, and are of a deep green. The flowers come out in loose spikes at the top of the stalks; these are small, and of a pale yellow without scent, and are succeeded by four-cornered pods like those of the former. It flowers, and the seeds are ripe at the same time with the former.
- These two plants have by some persons been supposed the same, but I have cultivated them thirty years, and have never found them alter. If their seeds are permitted to scatter, the plants will come up without care, and will thrive on any soil or situation, and upon walls, or in rubbish, in the same manner as the common Wall-flower.
- The second sort grows naturally upon old walls and

buildings in many parts of England; it is also cultivated in gardens for the fragrantcy of its flowers. When these plants grow upon walls or buildings, they seldom rise more than six or eight inches high, having very tough roots and firm stalks; the leaves are short, and sharp-pointed; and the flowers are small, but in gardens the plants will grow two feet high, and branch out wide on every side; the leaves are broader, and the flowers much larger; but in severe winters, when these plants are frequently killed in the gardens, those upon the walls will receive no injury, though they are much more exposed to the winds and frosts; for as these plants are stunted, and of a firmer texture, having but little juice, the cold never affects them.

There is a variety of this with very double flowers, which is propagated in the gardens from slips planted in the spring, which readily take root. There is one sort of this with variegated leaves, which is preserved in the gardens, but this is not quite so hardy as the plain.

The large, yellow, bloody Wall-flower, is also supposed to be a variety of this, which has been improved by culture; and this I am inclinable to believe, because I have frequently observed many of them degenerate to the common sort; but although I have many years sowed the seeds of the common sort from the walls, yet I could never find them alter, except in being larger, but not any of them approached toward the other varieties. The large bloody Wall-flower will frequently rise with double flowers from seeds, if they are carefully saved from such plants as have five petals; and these double flowers may be propagated by slips as the common sort, but the plants so raised will not produce such large spikes of flowers as those which are propagated by seeds.

There is also another variety with double blood-coloured flowers, whose petals are shorter and more numerous, approaching nearer to the common double Wall-flower, but much larger. This is called the Old Bloody Wall-flower. It is propagated from slips, in the same manner as the other double sorts. There are some intermediate varieties of these flowers, differing in the size and colour of their petals, which the florists distinguish as different; but as they constantly vary from seeds, they do not deserve notice.

The fourth sort grows naturally upon the Alps, and the mountains in Italy, where it rarely rises above six inches high; the leaves are very narrow, and the flowers grow in close spikes at the end of the branches; they are of a pale yellow, or brimstone colour, and the necks of the petals are much longer than the empalement; these have but little scent. When this sort is cultivated in gardens, it grows as large as the common Wall-flower, and makes a finer appearance, for the spikes of flowers are longer, and they grow much closer together; but they have little scent, which occasioned their being first neglected, and at present there are few, if any, of the plants remaining in the English gardens. It was titled the Straw-coloured Wall-flower by the gardeners.

The sorts with single flowers produce seeds in plenty, from which the plants are raised; but the largest and deepest coloured flowers should always be selected for seeds, because from seeds carefully saved, there will be fewer of the plants degenerate. The seeds should be sown in April, upon poor or undunged soil, and when the plants are fit to remove, they should be transplanted into nursery-beds, at about six inches distance each way; observing to water and shade them until they have taken fresh root; after which they will require no farther care, but to keep them clean from weeds all the summer; and at Michaelmas they may be transplanted into the borders of the flower-garden where they are designed to remain, that the plants may get good roots before the frost comes on. This is the method which is commonly practised with these flowers; but if the seeds are sown upon poor land,

O o o where

where they are designed to remain, and not transplanted, they will thrive, and endure the frost in winter much better than those which are removed; so that upon ruins or rubbish the seeds of these plants may be sown, where they will thrive and continue much longer than in good land; and in such places, if they are properly disposed, they will be very ornamental, and their flowers having a strong odour, will perfume the air to a considerable distance.

The Stock Gilliflowers are distinguished from the Wall-flowers by their hoary leaves. These agree with each other in their botanical characters, so are generally included in the same genus; but the gardeners remove them to a considerable distance, and treat them very differently; yet there is so great affinity between them, as that they may be treated in the same manner, and both will grow equally upon old walls or ruins; but as they have been separated by most of the writers on gardening, I have, in compliance with that custom, ranged them accordingly.

The fifth sort is now generally known by the appellation of ten Weeks Stock, but it is what was formerly titled Annual Stock Gilliflower, which of late has been applied to another species, which is biennial. This rises with a round smooth stalk about two feet high, dividing into several branches upward, garnished with spear-shaped hoary leaves, which are rounded at their ends, and placed without order, sometimes being almost opposite, and others alternate, and frequently three or four together of unequal sizes; at the ends of the branches the flowers are produced in loose spikes, which are placed alternate; the empalement of the flower is large, erect, and slightly cut into several acute parts at the top; the petals are large and heart-shaped, spreading open in form of a cross; the pods are long, cylindrical, and have a longitudinal furrow on one side, which opens in two cells, which are filled with flat roundish seeds, having a thin border. It flowers in July and August, and the seeds ripen in October.

Of this sort there are the red, the purple, the white, and striped, with single flowers, and the same colours with double flowers; these are very great ornaments in the borders of the flower-garden in the autumn, when there is a scarcity of other flowers; and if the seeds are sown at two or three different times, the flowers may be continued in succession near three months. The first sowing should be about the middle of February, upon a very slender hot-bed, just to bring up the plants, which must be guarded against frost; and when they are fit to remove, they should be transplanted into the nursery beds, at about three or four inches distance, observing to water and shade them till they have taken root, and afterward to keep them clean from weeds; in these beds they may remain five or six weeks to get strength, and may then be planted into the borders of the flower-garden, where they are to remain: if these are transplanted when there is rain, they will soon take root, after which they will require no farther care. From these early plants good seeds may be expected, therefore some of the finest plants of each colour should be preserved, and marked for seeds, which, when ripe, should be carefully cut before the frost pinches it, and the stalks tied up in small bundles, and hung up in a dry room till the pods are well dried, when the seeds may be rubbed out and preserved for use.

The sixth sort is a biennial plant, though when the seeds are sown early in the spring, the plants often flower the following autumn; but these plants which are so forward, are often killed in winter; therefore it is much better to sow them in May, that the plants may not grow too rank the first season; they will live through the winter, and produce large spikes of flowers the second year.

This is commonly called the Queen's Stock Gilliflower by the gardeners, and differs greatly from the other sorts, though many of the late botanists have supposed they were only feminal variations; but from near forty years experience in the culture of these

plants, I can affirm, that the species here enumerated, do not alter from one to the other, though they frequently vary in the colour of their flowers.

It rises with a strong stalk, which is almost shrubby; a foot high or more, having oblong, spear-shaped, hoary leaves, which are frequently waved on their edges, and turn downward at the extremity; from the stalk is sent out many lateral branches, which are garnished with the same shaped leaves, but smaller; these side branches are each terminated by a loose spike of flowers, each having an oblong woolly empalement, and consist of four large roundish petals, which are indented at the end. These usually appear in May and June, but the same plants frequently continue flowering most part of the summer. The seeds ripen in autumn, and the plants generally perish soon after; but when any of them grow in dry rubbish, they will last two or three years and become shrubby; but those with single flowers, are not worth preserving after they have perfected their seeds. The flowers of this sort vary in their colour; some are of a pale red, others are of a bright red, and some are curiously variegated, but those of the bright red are generally most esteemed. There is always a great number of double flowers produced, if the seeds are well chosen, frequently three parts in four of the plants will be double; and as the plants divide into many branches, they make a fine appearance during their continuance in flower.

The seventh sort is known by the title of Brompton Stock Gilliflower, I suppose from its having been there first cultivated in England. This rises with an upright, strong, undivided stalk, to the height of two feet or more, garnished with long hoary leaves, which are reflexed, and waved on their edges, and at the top form a large head; out of the center of these arises the flower-stalk, which, when the plants are strong, is frequently a foot and a half long, putting out two or three short branches toward the bottom; the flowers of this kind have longer petals than any of the other sorts, and are formed into a pyramidal spike; but those with single flowers are loosely disposed, because the flowers having but few petals, do not fill the spike, as those do which are double; for these often have so many petals, as to render each flower as large and full as small Roses; and when they are of a bright red, make a pretty appearance, being excelled by none of the flowery tribe; but the plants of this sort produce but one spike, in which it differs from all the other kinds, and being constant in this particular, I think is sufficient to establish a distinct species. This sort is generally biennial, though many times the plants are preserved longer; but they are always stronger the first year of their flowering, than they will be after; so that the seeds are sown every spring, to continue a succession of flowering plants.

The eighth sort is the White Stock Gilliflower, which is of longer duration than either of the other sorts. I have frequently had these plants live three or four years, which have become shrubby; their stalks have been three feet high, and branched out on every side, so as to appear like shrubs; these seldom send out flower-stalks from the center of the plant, but it is the side branches which produce the flowers, and these side branches divide into several other, which is not common to the other sorts. There are always many double flowers rise from seeds of this sort, when they are well chosen; some years I have scarce had enough single flowers to preserve the kind. The varieties of this are few, sometimes a few of the plants will produce pale flesh-coloured flowers, and now and then some have been purple; and as that sort of Stock Gilliflower, which is titled the Twickenham Purple, will sometimes come with flowers variegated with white, I have been inclinable to think these two may be varieties of each other; and the rather, because the plants agree with each other in their external habit; for neither of these put out their flower-stems from the center of the plants, but always on their

their side, so that these are undoubtedly a distinct species from the former.

The ninth sort is known by the title of White Wall-flower, among the gardeners and florists. This rises with a greenish stalk a foot high, dividing into many branches, garnished with narrow, smooth, spear-shaped leaves, of a lucid green, and of thicker consistence than those of any of the other sorts; they come out without any order, are near three inches long, and about half an inch broad in the middle; the flowers are produced in loose spikes at the end of the branches, which are of a pure white, and have a great fragrantcy, especially in an evening or in cloudy weather; the flowers are succeeded by oblong compressed pods like those of the other species. There is a variety of this with double flowers, which is propagated by cuttings or slips, in the same manner as the double Wall-flowers; but these plants require protection from great rains, and frost in winter; so if they are planted in pots, and placed under a common frame in winter, where in mild weather they may enjoy the open free air, and be covered from hard rains and frost, they may be preserved several years.

Sometimes many of the plants with double flowers will come up from seeds, but not so frequent as some of the other sorts. I have for several years raised more than one hundred plants in a season, without obtaining one double flower; and from the seeds of these, have the following year had more than half the plants with double flowers: but this is not to be expected often.

The seeds of the tenth sort were sent me by Dr. Linnæus, from Upsal in Sweden. This plant rises about six inches high, with an herbaceous swelling stalk; the leaves are produced in clusters at the top, which are very hoary, waved on their edges, have obtuse points, and set very close to the stalk; the flowers are produced in slender spikes from the side of stalk; these are purple, but not so fragrant as many of the other sorts; the pods are woolly, and recurve backward at the end.

All these sorts flower in May and June, at which time they are the greatest ornament to the flower-garden, therefore deserve our care to cultivate them as much as any of the flowery tribe; but in order to have many double flowers, there must be great care taken in the choice of plants for seeds, without which there can be little hopes of having these flowers in perfection. The only sure way of getting many double flowers, is to make choice of those single flowers which grow near many double ones; for I have always found those seeds which have been saved from plants growing in beds close to each other, where there happened to be many double flowers among them, have produced a much greater number of plants with double flowers, than those which have been saved from plants of the same kinds, which grew single in the borders of the flower-garden; so that there should be a small bed of each kind planted on purpose to save seeds in the flower-nursery; or if they are sown there, and the plants thinned properly when they are young, they need not be transplanted; for I have always observed the plants which have come up from scattered seeds, which have not been transplanted, endure the frost much better than those which have been removed; for as these plants send out horizontal roots from the bottom of their stems, which spread near the surface of the ground, so when they are transplanted, the roots are forced downward out of their natural direction; and if their stalks were grown tall before removal, they are generally planted low in the ground, whereby they are apt to rot, if the ground is moist, or the winter should prove wet; therefore where they can be left unremoved, there will be a better chance of their living through the winter; and as these beds need not be of great extent, so when the winter proves very severe, it will not be much trouble or expence to arch the beds over with hoops, and cover them with mats in frosty weather, by which method they may be always preserved.

The ground where these seeds are sown, must not have any dung, for in rich land the plants will grow very vigorous in summer, but when the frost comes on, or the heavy rains in autumn, either of which will soon destroy them; for these plants will thrive upon rocks or old walls, as was before observed; and in such situations they will live, when all those which are planted in gardens are destroyed. The best time to sow the seeds is about the beginning of May; and if the season should prove dry, it will be proper to shade the beds with mats every day, to prevent the earth from drying too fast; but the covering must be taken off every evening, to admit the dews of night; and they should be gently watered in the evening two or three times a week. When the plants first appear, with their two seed-leaves, they are often attacked by flies, especially in dry hot seasons; therefore to prevent their destroying of the plants, the covering should be continued over them during the heat of the day, and the plants frequently refreshed with water, which will keep them in a growing state, so the flies will not infest them; for I have always observed, they never attack any plants unless they have been stunted in their growth: when the plants have got strength, they will be secure from this danger, and the coverings may be removed; after this the plants will require no farther care but to keep them clean from weeds, and to be thinned to the distance of nine inches or a foot asunder, that they may have proper room to grow, and not draw each other up tall and weak. The plants which are drawn out of these beds to thin them, may be planted in the borders of the flower-garden, where they are designed to remain, and the sooner they are removed, when the plants have got six or eight leaves, the more likely they will be to live through the winter; because their roots will not have extended themselves so far, so cannot be planted deep in the ground, and may take their natural direction; therefore whenever these plants are removed, it is always the best way to do it when they are young.

The farther care of the plants which are left in the beds, will be to cover them in winter with mats; and when they come to flower, all those which are not of good colours, or whose flowers are small, should be drawn out as soon as they appear, that they may not impregnate those which are designed for seeds with their farina; but those with double flowers should by no means be removed, nor should their flowers be cut off, but suffered to fade among the single ones, by which the seeds will be improved; it will also be a sure method of preserving each sort in perfection, to have them separate from each other, in distinct beds; though I think there is no danger of any of the species altering, by the mixture of their farina, but their colours are liable to be changed by it; so that in order to continue those pure, they should not stand too near each other.

The time for sowing the seeds before-mentioned, must be understood to be for the sorts which are biennial; for the annual, or ten Weeks Stock Gilliflower should be for the first season sown in February, as was before directed; and to succeed these, there should be another parcel sown in March; and those who are curious to continue these flowers late in the autumn, should sow a parcel of the seed the latter end of May; and if these last sown plants are upon a warm border, where they may be covered, by placing glasses before them in winter, or covering them with mats, they may be continued in flower till Christmas; and if some of the plants are potted, and put under a hot-bed frame in autumn, where they may enjoy the open air in mild weather, and be screened from hard rains and frost; by which method I have known these plants kept flowering all the winter, when the winters have not been very severe.

There are some who propagate the double Stock Gilliflowers by slips and cuttings, which will take root when properly managed; but the plants so raised are never so strong as those which come from seeds, and

their spikes of flowers are always very short, and have not half the beauty; therefore it is not worth while to practise this method, unless for those sorts which cannot be obtained with any certainty from seed.

The eleventh sort grows naturally in the south of France, Spain, and Italy, near the sea coast. This rises near a foot high, with a ligneous stalk, dividing into many small branches, garnished with narrow hoary leaves, which are entire, and rounded at their extremity; the flowers are produced in loose spikes at the end of the branches, which are smaller than those of either sort before-mentioned, of a bright red at their first appearing, but fade to a purple before they fall off. The stalks, leaves, and the whole plant is very white, and by its woody stalks hath the appearance of a perennial plant, but it generally perishes in autumn. The seeds of this sort should be sown in autumn, upon a warm border, where the plants are designed to remain; when the plants come up, they will require no farther care but to keep them clean from weeds, and thin them where they come up too close. These autumnal plants will flower early in June, so will produce good seeds; but those which are sown in the spring will flower in July and August, so that from these there cannot be any certainty of having ripe seeds: however, by sowing the seeds at two or three different seasons, there may be a succession of flowers continued for three or four months.

The twelfth sort is commonly sown in gardens, sometimes as an edging for borders, but more generally in patches between taller growing flowers: it is titled sometimes Dwarf annual Stock Gilliflower, and by others it hath the appellation of Virginia Stock Gilliflower. This seldom rises more than six inches high, sending out many branches from the root, which intermix and grow irregular; these are garnished with spear-shaped leaves, rounded at their ends, and sit close to the branches; the flowers come out in loose spikes at the end of the branches, which are of a purple colour, composed of four petals in form of a cross, and are succeeded by slender pods like those of the other sorts. If the seeds of this sort are sown in patches, at two or three different times, the first in autumn, the second the latter end of March, and the third the end of April, or the beginning of May, in the borders of the flower-garden, they will make a variety, when intermixed with other low growing annual flowers, for three months.

The thirteenth sort rises near two feet high, sending out many upright branches from the bottom, which are thinly garnished with spear-shaped leaves, the lower ones being a little indented; the flowers come out single, at great distances from each other, toward the upper part of the branches; these are small, of a purplish red colour, and soon fall away, being succeeded by long taper pods, with awl-shaped points. This is an annual plant, which may be treated in the same manner as the last mentioned sort; but as it hath little beauty, it is not often cultivated in gardens. The fourteenth sort grows naturally on the sea coasts in Italy, Spain, and Portugal. This is also an annual plant, which branches out from the root into many declining stalks; the lower leaves are about two inches long, and three quarters of an inch broad, very deeply sinuated on their edges, and hoary; those upon the stalks are of the same form, but much smaller; the flowers are produced from the sides of the stalks singly, and at the top in loose spikes; the empalements of the flowers are covered with a white down, as are also the end of the branches; the flowers are purple, composed of four leaves placed in form of a cross; the pods are about three inches long, taper, woolly, and at their ends are divided into three parts, which spread into a triangle. It flowers in July, and when the season is favourable, the seeds will ripen in autumn; but if the seeds are sown in autumn on a warm border, the plants will live through the winter, and these will flower early in June, so from these good seeds may be obtained from them.

The fifteenth sort grows naturally on the sea coasts in the south of France and Spain, where it continues three or four years; the stalk is erect, and the whole plant is covered with a white down; the lower leaves are broad, spear-shaped, obtuse, and alternately indented; the flowers are flesh-coloured, composed of four petals like the other species, and are succeeded by long woolly pods.

This may be propagated by seeds in the same manner as the other sorts; and if the plants grow in rubbish, they will live through the winter better than in rich earth.

The sixteenth sort is of humble growth, seldom rising above eight or nine inches high; the leaves are very narrow, and indented on their edges; the stalk becomes shrubby, to which the flowers grow very close; these are of a worn out purple colour, so make but little appearance. It grows naturally in Spain and Italy, and is not so hardy as the other sorts, therefore requires some protection in winter.

The seventeenth sort grows naturally in Portugal. This is a low annual plant with pointed leaves, whose borders are indented as if torn; the empalement of the flower is hoary; the flowers have four purple petals placed in form of a cross, which are succeeded by knobbed-pointed pods inclosing flat seeds.

If the seeds of this kind are sown in the spring upon sheltered borders, where the plants are to remain, and they are thinned and kept clean from weeds, the plants will flower in July, and produce ripe seeds in autumn.

CHELIDONIUM. Tourn. Inst. R. H. 231. tab. 116. Lin. Gen. Plant. 572. *Chelidonium majus*. Raii Meth. Plant. 100. *Glaucium*. Tourn. Inst. R. H. tab. 130. *Celandine*, or *Greater Celandine*, in French *Chelidone* or *Eclair*.

The CHARACTERS are,

The flower hath a roundish empalement, composed of two concave obtuse leaves, which fall off; it hath four large roundish petals, which spread open and are narrow at their base; in the center is situated a cylindrical germen, attended by a great number of stamina, which are broad at the top, and are terminated by oblong, compressed, twin summits. Upon the germen is situated a bifid stigma in form of a head. The germen afterward becomes a cylindrical pod, with one or two cells, opening with two valves, and filled with many small seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, intitled Polyandria Monogynia, the flower having many stamina and one style. To this genus he has joined the *Glaucium* of Tournefort, whose characters very well agree with those of *Celandine*, so are very properly brought together.

The SPECIES are,

1. **CHELIDONIUM** (*Majus*) pedunculis umbellatis. Lin. Gen. Plant. 505. *Celandine with an umbellated foot-stalk*. *Chelidonium majus vulgare*. C. B. P. 144. *Greater common Celandine*.
2. **CHELIDONIUM** (*Laciniatum*) foliis quinque lobatis, lobis angustis acute laciniatis. *Celandine whose leaves are composed of five narrow lobes, which are cut into many acute segments*. *Chelidonium majus laciniato flore*. Clus. Hist. 203. *Greater Celandine with a jagged flower*.
3. **CHELIDONIUM** (*Glaucium*) pedunculis unifloris, foliis amplexicaulibus sinuatis, caule glabro. Lin. Sp. Plant. 506. *Celandine with single flowers on the foot-stalks, sinuated leaves which embrace the stalks, and a smooth stalk*. *Glaucium flore luteo*. Tourn. Inst. R. H. 351. *Glaucium with a yellow flower*; and the *Papaver corniculatum luteum*. C. B. P. 171. *Yellow horned Poppy*.
4. **CHELIDONIUM** (*Corniculatum*) pedunculis unifloris, foliis sessilibus pinnatifidis, caule hispido. Lin. Sp. Plant. 506. *Celandine with single flowers upon the foot-stalks, leaves set close to the stalks which have winged points, and a rough stalk*. *Glaucium hirsutum flore Phœnicio*. Tourn. Inst. R. H. 253. *Hairy Glaucium, or horned Poppy, with a scarlet flower*.
5. **CHELIDONIUM** (*Glabrum*) pedunculis unifloris, foliis semiamplexicaulibus, dentatis, glabris. *Celandine with foot-*

C H E

foot-stalks having a single flower, and smooth indented leaves, which half embrace the stalks. Glaucium glabrum flore Phœnicio. Tourn. Inst. 254. Smooth horned Poppy with a scarlet flower.

6. CHELIDONIUM (*Hybridum*) pedunculis unifloris; foliis pinnatifidis, linearibus, caule lævi. filiquis trivalvibus. Lin. Sp. Plant. 724. *Celandine with single flowers upon the foot-stalk, many pointed narrow leaves, and a smooth stalk. Glaucium flore violaceo. Tourn. Inst. 254. Horned Poppy with a Violet-coloured flower.*

The first sort is the common Celandine which is used in medicine, and is esteemed aperitive and cleansing, opening obstructions of the spleen and liver; and is of great use in curing the jaundice and scurvy. This grows naturally on the side of banks; and in shady lanes in many parts of England; so is seldom cultivated in gardens; for if the seeds are permitted to scatter, the ground will be plentifully stored with plants to a considerable distance. It flowers in May, at which time the herb is in the greatest perfection for use.

The second sort is found growing in a few particular places, where the seeds have been formerly sown, or the plants cast out of gardens. This is by some supposed to be only a variety of the first, but I have propagated this by seeds above forty years, and have constantly found the plants produced to be the same as those from which the seeds were saved, and never vary, nor have I ever observed the first alter to this. The leaves of this are divided into narrow long segments, which are deeply jagged on their edges, and the petals of the flower are cut into many parts, in which it differs from the first. If the seeds of this sort are permitted to scatter, they will fill the ground with plants. They both delight in shade. There is a variety of this with double flowers, which generally rises the same from seeds, which is not usual in many other plants; however, this variety may always be preserved by parting the roots.

The third sort is known by the title of Horned Poppy; it was so called from the resemblance which the flower bears to the Poppy, and the long seed-vessel, which is like a horn. It grows naturally upon the sandy and gravelly shores by the sea, in many parts of England, from whence the seeds have been brought into gardens, where it is sometimes allowed to have place for the sake of variety. This plant abounds with a yellow juice which flows out from every part, when broken. It sends out many thick gray leaves, which are deeply jagged; the stalks are strong, smooth, and jointed, which rise near two feet high, and divide into many branches. These are garnished with leaves at each joint; those on the lower part of the stalks are long, broad, and deeply jagged, but the upper leaves are entire and almost heart-shaped: they closely embrace the stalks with their base; from the bosom of the leaves come out the short foot-stalks of the flowers, each supporting one large yellow flower, composed of four broad petals, which spread open like the garden Poppy, in the center of which are a great number of yellow stamina, surrounding a long cylindrical germen, crowned by an arrow-pointed stigma, which is permanent, remaining upon the top of the horned seed-vessel, which grows nine or ten inches long, having a longitudinal furrow on one side, where it opens when ripe, and lets out the seeds. This is a biennial plant, which flowers the second year, and perishes soon after the seeds are ripe.

If the seeds of this plant are permitted to scatter, they will fill the ground near them with plants; so that it is not a proper plant for a flower-garden; but if a few of the seeds are scattered about in rock work, the plants will rise without trouble, and in such places will have a pretty effect. And if the seeds are permitted to scatter, there will always be a supply of young plants; so the only care they will require, is to pull them up when they multiply too fast. It flowers in June and July, and the seeds ripen in autumn.

C H E

The fourth sort grows naturally in Spain, Italy, and some parts of Germany, from whence the seeds have been brought to England. The leaves of it are deeply jagged and hairy; of a pale green, and grow close to the stalks: those at the bottom lie on the ground, and are broader than those above. The stalks are a foot and a half high, having a single jagged leaf placed at each joint; these have many divisions; from their origin to the point, which is extended longer than the lower leaves. The flowers come out from the bosom of the leaves; these are composed of five broad obtuse petals, which are of a dark scarlet colour, and soon fall off. In the center of each is situated an oblong germen, having no style, but supports a bifid stigma; this is attended by a great number of short stamina, terminated by obtuse summits. The germen afterward becomes a long taper pod, on the apex of which the bifid stigma remains, sitting on the middle partition, which divides the pod into two cells, which are filled with small seeds. The flower hath an empalement composed of two hollow leaves, which are closely set with short prickles; this falls away when the flower is expanded. It flowers in June and July, and the seeds ripen in autumn. As the flowers of this plant are but of short duration; they do not make any considerable figure; but the foliage of the plant is very elegant, and might be introduced by way of ornament to furniture with great advantage, being very picturesque: it may also be wrought into patterns for silks, and painted upon porcelain, where it would have a very good effect. If the seeds of this plant are sown in the autumn, they will more certainly grow than those which are sown in the spring; which frequently, in dry seasons, do not come up the same year, or at least not before autumn; whereas those sown in autumn, frequently come up soon after, or if not at that season, do not fail coming up in the spring; and these plants come early to flower, so that good seeds may always be obtained from them. They should be sown where the plants are to remain, and they will require no other care but to thin them where they are too close, and keep them clean from weeds.

The fifth sort differs from the fourth, in having broader leaves, which are not so deeply divided; the whole plant is smooth, and the flowers are larger, but are of the same colour: this is also an annual plant, and requires the same treatment as the last.

The sixth sort grows naturally among the Corn, in some parts of England. This is also an annual plant, whose seeds should be sown in autumn, for those which are sown in the spring seldom succeed. The leaves of this sort are finely jagged, and divided into narrow segments, somewhat like those of Buckhorn Plantain; they are smooth, of a lucid green, and are commonly opposite. The stalks rise little more than a foot high, dividing into two or three branches upward, garnished with small leaves of the same form as those below. The flowers are sustained by slender foot-stalks, which come out from the wings of the leaves; these are composed of four obtuse petals, of a Violet colour, in the center of which is situated a cylindrical germen, attended by a great number of stamina; the germen afterward becomes a long cylindrical pod, like those of the other species. The flowers of this plant are very fugacious, seldom lasting above three or four hours before the petals drop off, especially in clear weather. It flowers in May, and the seeds ripen in July, and the plants soon after perish. If the seeds are permitted to scatter, the plants will come up without care as the others.

CHELONE [χελών, Gr. a tortoise.] Tourn. Art. R. S. 1706. tab. 7. fol. 2. Lin. Gen. Plant. 666.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five parts, and is permanent; the flower is of the ringent kind, having a short cylindrical tube, which is swollen at the chaps, where it is oblong, convex above, and plain below; the mouth is almost closed; the upper lip is obtuse and indented,

P P P

dentel,

dentate, the lower lip is lightly cut into three parts. It hath four stamina, which are inclosed in the backside of the petal, the two side ones being a little longer than the other, which are terminated by oval hairy summits. It hath an oval germen supporting a slender style, crowned by an obtuse stigma; the germen afterward becomes an oval capsule having two cells, which are filled with flat roundish seeds having a border.

This genus of plants is ranged in the second section of Linnæus's thirteenth class, intitled Didynamia Angiospermia, from the flower having two long and two short stamina, and the seeds being included in a capsule.

The SPECIES are,

1. CHELONE (*Glabra*) foliis lanceolatis, acuminatis, sessilibus, obsolete serratis, radice reptatrice. *Chelone* with pointed spear-shaped leaves, set close to the stalks, with small serratures on their edges, and a creeping root. *Chelone* Acadensis flore albo. Tourn. Act. R. Par. 1706. *Chelone* of Acadia, with a white flower.
2. CHELONE (*Purpurea*) foliis lanceolatis, obliquis, petiolatis, oppositis, marginibus acutè serratis. *Chelone* with oblique spear-shaped leaves, growing opposite on foot-stalks, and their borders sharply sawed. *Chelone* floribus speciosis pulcherrimis, colore rosæ damascenæ. Clayt. Flor. Virg. 71. *Chelone* with a very beautiful looking flower, the colour of the Damask Rose.
3. CHELONE (*Hirsuta*) caule foliisque hirsutis. Lin. Sp. Plant. 611. *Chelone* with hairy stalks and leaves. *Digitatis* Virginiana, panacis coloni foliis, flore amplo, pallascente. Pluk. Mant. 64. *Virginia* Foxglove with Clowns all-beal leaves, and a large pale flower.

The first sort grows naturally in most parts of North America. This is called by Joscelyn, in his New England Rarities, the Humming Bird-tree. It hath a pretty thick jointed root, which creeps under ground to a considerable distance, sending up smooth channelled stalks, which rise about two feet high, garnished with two leaves at each joint, standing opposite without foot-stalks; these are three inches and a half long, and about three quarters of an inch broad at their base, where they are broadest, and diminish gradually to a sharp point; they have small serratures on their edges, which scarcely appear. The flowers grow in a close spike at the end of the stalks; they are white, and have but one petal, which is tubular, and narrow at the bottom, but swells upward, almost like the Foxglove flower; the upper side is bent over and convex, but the under is flat, and slightly indented in three parts at the end. When the flowers fall off, the germen turns to an oval capsule sitting in the empalement, filled with roundish compressed seeds, which have a thin border. It flowers in August, and when the autumn proves favourable, the seeds will sometimes ripen in England; but as the plants propagate so fast by their creeping roots, the seeds are seldom regarded. The best time to transplant the roots is in autumn, that they may be well established in the ground before the spring, otherwise they will not flower so strong, especially if the season proves dry; but when they are removed in the spring, it should not be later than the middle of March, by which time their roots will begin to push out new fibres. They will thrive in almost any soil or situation, but their roots are apt to creep too far, if they are not confined, and sometimes intermix with those of other plants; and then their stalks stand so far distant from each other, as to make but little appearance; therefore they should be planted in pots, which will confine their roots, so that in each pot there will be eight or ten stalks growing near each other, when they will make a tolerable good appearance. This plant is very hardy, so is not injured by cold, but it must have plenty of water in hot weather.

The second sort was discovered in Virginia by Mr. Clayton, who sent it to England: the roots of this do not creep so far as those of the first, the stalks are stronger, and the leaves much broader, and are oblique; they are deeply sawed on their edges, and stand upon short foot-stalks: the flowers are of a

bright purple colour, so make a finer appearance. This flowers at the same time with the first, and is propagated by parting of the roots in the same manner.

The third sort I received from New England, where it grows naturally: this is near to the first sort, but the stalks and leaves are very hairy, and the flower is of a purer white. It flowers at the same time with the former, and requires the same treatment.

As these plants flower in the autumn, when there is a scarcity of other flowers, it renders them the more valuable, especially the second sort, whose flowers make a very pretty appearance, when they are strong; and if some of them have a shady situation in the summer, they will flower later in the autumn.

CHENOPODIA-MORUS. See BLITUM.

CHENOPODIUM [*χρηνοπόδιον*, Gr.] Tourn. Inst. R. H. 506. tab. 288. Lin. Gen. Plant. 272: Goosefoot, or Wild Orach.

The CHARACTERS are,

It hath a permanent empalement, composed of five oval concave leaves: the flower hath no petal, but in the center it hath five stamina placed opposite to the leaves of the empalement, and of the same length, terminated by roundish twin summits; it hath a round germen supporting a short double style, crowned by an obtuse stigma. The germen afterward becomes a five-cornered fruit inclosed in the empalement, containing one roundish depressed seed. Linnæus places this genus in the second section of his fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. CHENOPODIUM (*Bonus Henricus*) foliis triangulari-fagittatis, integerrimis spicis compositis aphyllis. Hort. Cliff. 84. Goosefoot with arrow-shaped triangular leaves which are entire. *Chenopodium folio triangulo*. Tourn. Inst. 506. Goosefoot with a triangular leaf, called English Mercury, All Good, or Good Henry.
2. CHENOPODIUM (*Vulvaria*) foliis integerrimis rhombicovatis, floribus conglomeratis axillaribus. Flor. Succ. 216. Goosefoot with entire, oval, rhomboidal leaves, and flowers growing in clusters on the side of the stalks. *Chenopodium foetidum*. Tourn. Inst. 506. Stinking Orach.
3. CHENOPODIUM (*Scoparia*) foliis lineari-lanceolatis, planis, integerrimis. Hort. Cliff. 86. Goosefoot with narrow spear-shaped leaves, which are plain and entire. *Chenopodium lini folio villosa*. Tourn. Inst. R. H. Goosefoot with a hairy Flax leaf, commonly called Belvedere, or Summer Cypress.
4. CHENOPODIUM (*Botrys*) foliis oblongis, sinuatis, racemis nudis multifidis. Hort. Cliff. 84. Goosefoot with oblong sinuated leaves, and naked multifid spikes of flowers. *Chenopodium ambrosioides folio sinuato*. Tourn. Inst. 506. Goosefoot, like Ambrosia, with sinuated leaves, commonly called Oak of Jerusalem.
5. CHENOPODIUM (*Ambrosioides*) foliis lanceolatis, dentatis, racemis foliatis simplicibus. Hort. Cliff. 84. Goosefoot with spear-shaped indented leaves, and single leafy spikes of flowers. *Chenopodium ambrosioides Mexicanum*. Tourn. Inst. 506. Mexican Goosefoot, like Ambrosia, commonly called Oak of Cappadocia.
6. CHENOPODIUM (*Fruticosum*) foliis lanceolatis, dentatis, caule fruticoso. Goosefoot with spear-shaped indented leaves, and a shrubby stalk. *Chenopodium ambrosioides Mexicanum fruticosum*. Boerh. Incl. alt. 2. p. 90. Shrubby Mexican Orach.
7. CHENOPODIUM (*Multifidum*) foliis multifidis, segmentis linearibus, floribus axillaribus sessilibus. Lin. Sp. 320. Goosefoot with multifid leaves, linear segments, and flowers set close to the stalk. *Chenopodium sempervirens, foliis tenuiter laciniatis*. Hort. Elth. 78.

There are many other species of this genus, some of which grow naturally on dunghills and the side of ditches, in most parts of England, where they often become very troublesome weeds; for which reason, I have not enumerated them here.

The first sort is found growing naturally in shady lanes in many parts of England, but it is very doubtful if the seeds have not been cast out of gardens originally,

C H E

Originally, because this plant was formerly cultivated in kitchen-gardens for use; and in some of the northern countries, the people still preserve it in their gardens as an esculent herb; which in the spring season, they dress in the same manner as Spinach, for which it is a substitute. But, as the latter is a much better herb, it has obtained the preference very justly, in all the countries where the culture of the kitchen-garden is understood.

The second sort is very common upon dunghills, and in gardens, in most parts of England: it is seldom cultivated, except in some physic-gardens; for the markets in London are supplied with it by the herb-women, who gather it in the places where it grows wild.

The third sort is sometimes cultivated in gardens; it is a beautiful plant, which is naturally disposed to grow very close and thick, and in as regular a pyramid as if cut by art. The leaves are of a pleasant green; and were it not for that, it hath so much of the appearance of a Cyprus-tree, that at some distance it might be taken for the same, by good judges: the seeds should be sown in autumn; and in the spring, when the plants are come up, they may be planted into pots of good earth, and kept supplied with water in dry weather: these pots may be intermixed with other plants to adorn court-yards, &c. where they will appear very handsome, until their seeds begin to swell and grow heavy, which weigh down and displace the branches; at which time the pots should be removed to some abject part of the garden, to perfect their seeds; which, if permitted to fall upon the ground, will come up the next spring; so that you need be at no more trouble in propagating these plants, but only to transplant them where you intend they should grow.

The fifth sort was formerly used in medicine; but although it still continues in the catalogue of simples annexed to the London Dispensatory, yet is very seldom used at present. This plant may be propagated by sowing the seeds in an open border of good earth in the spring, where it will perfect its seeds in autumn; which, if permitted to shed upon the ground, will arise as the former.

The fourth sort was brought from America, where the seeds are called Worm Seed, I suppose from some quality contained in it, which destroys worms in the body.

This is propagated by sowing the seeds in the spring, as the before-mentioned sort, and will perfect its seed in autumn; after which, the plant decays to the ground: but if the root be preserved in shelter under a common frame in winter, the stalks will rise again the following spring.

The leaves of this plant emit a very strong odour when bruised, somewhat like those of the Ambrosia, for which the plants are preserved in gardens, for the flower hath no beauty. This plant grows naturally in most parts of North America, where it is generally called Worm Seed. It sends up several stalks from the root, which rise about two feet high, garnished with oblong leaves a little indented on their edges, of a light green, and placed alternately on the stalks; the flowers come out from the wings of the leaves on the upper part of the branches, in loose spikes: these appear in July, and the seeds ripen in September; which, if permitted to scatter, the plants will come up the following spring, when a few of them may be transplanted into pots filled with kitchen-garden earth, to be preserved through the winter; and the others may be planted in the common borders, where they will flower and perfect their seeds; but unless the winter is very favourable, the roots will be destroyed.

The seeds of all the species of this genus will succeed best, if they are sown in autumn; for when they are sown in the spring, they frequently lie a whole year before the plants come up; therefore where the seeds of any of them scatter, the plants will come up much better than those which are sown by hand.

C H I

The fifth sort is annual: this also grows naturally in North America, from whence I have frequently received the seeds. It is also a native of many of the warm countries in Europe. This hath many oblong leaves at the bottom, which are deeply sinuated on both sides, somewhat like those of the Oak-tree; from whence it received the title of Oak of Jerusalem. These are purple on their under side, and when bruised, emit a strong odour. The stalks rise about eight or nine inches high, dividing into several smaller branches. The lower part of these is garnished with leaves of the same shape with those below, but are smaller. The flowers grow in naked loose spikes, divided into many parts: they are small, herbaceous, and are succeeded by small round seeds. This sort flowers in June and July, and the seeds ripen in autumn.

The sixth sort hath leaves very like those of the fourth, and have the same scent: but this hath a shrubby stalk, which rises five or six feet high, and divides into many branches. It is a native of America, and must be housed in the winter, for it will not live through the winter in England in the open air. It is easily propagated by cuttings during any of the summer months, which, if planted in a shady border, and duly watered, will soon take root; and then may be planted in pots filled with light earth, and placed in the shade till they have taken new root, after which they may be placed with other hardy exotic plants in a sheltered situation during summer; and when the frost comes on, they must be removed into the green-house; but they only require protection from hard frosts, and should have plenty of air in mild weather. This grows naturally in the Brasils.

The seventh sort grows naturally at Buenos Ayres: this rises with a shrubby stalk three or four feet high, garnished with oblong leaves, which are cut into many linear segments; the flowers sit close to the stalks, which, like the other species of this genus, have no petals, but the empalement incloses five slender stamina: the germen supports two styles, crowned by obtuse stigma.

This is a perennial plant, which retains its leaves through the year, so will add to the variety in a green-house in winter, but has little other beauty to recommend it. This may be propagated by cuttings, which, if planted in a bed of light earth during any of the summer months, and duly shaded and watered, will put out roots; then they may be transplanted into pots, and may be placed with other hardy exotic plants in summer, but must be sheltered from frost in winter.

CHERRY-LAUREL. See PADUS.

CHERRY-TREE. See CERASUS.

CHERVIL. See SCANDIX.

CHESNUT. See CASTANEA.

CHESNUT, the Horse. See ESCULUS.

CHIONANTHUS. Lin. Gen. Plant. 21. The Fringe, or Snowdrop-tree. This title was given to this plant by Dr. Van Royen, from the whiteness of its flowers: the inhabitants of America, where this tree is a native, call it Snowdrop-tree, for the same reason: and the Dutch call it Sneebaum, i. e. Snow-tree, on the same account.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is erect, and cut into four acute parts; the flower is of one petal, having a short spreading tube the length of the empalement, and the upper part is cut into four very long narrow segments, which are erect. It hath two short stamina inserted in the tube of the petal, which are terminated by upright heart-shaped summits. In the center is placed the oval germen, supporting a single style, crowned by an obtuse trifid stigma. The germen afterwards becomes a round berry with one cell, inclosing one hard seed.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia, the flower having two stamina and one style.

We have but one SPECIES of this plant in the English gardens, viz.

CHIONANTHUS pedunculis trifidis trifloris. Lin. Sp. Plant. 8. *Snowdrop-tree, or Fringe-tree, with trifid foot-stalks supporting three flowers.* Amelanchier Virginiana laurocerasi folio. Pet. Hor. Sicc. 241. *Virginia Amelanchier with a Laurel leaf.*

This shrub is common in South Carolina, where it grows by the side of rivulets, and seldom is more than ten feet high: the leaves are as large as those of the Laurel, but are of a much thinner substance; the flowers come out in May, hanging in long bunches, and are of a pure white, from whence the inhabitants call it Snowdrop-tree; and, from the flowers being cut into narrow segments, they give it the name of Fringe-tree. After the flowers have fallen away, the fruit appears, which becomes a black berry, about the size of Sloes, having one hard seed in each.

This tree is now more common in the curious gardens in England, than it was a few years since; there having been many young plants raised from the seeds, which have been brought from America lately: there have also been some plants propagated by layers, though there is great uncertainty of their taking root, which they seldom do in less than two years; nor will they ever take root, unless they are well supplied with water in dry weather.
